for each $(t,\xi) \in \mathbb{I} \times \mathbb{V}$, where ω is a certain comparison function, then $\mathbb{K}$ is locally invariant with respect to f. This condition reduces to the classical Nagumo's tangency condition when applied to $\xi \in \mathbb{K}$, and this simply because, at each such point $\xi \in \mathbb{K}$, $\operatorname{dist}(\xi;\mathbb{K}) = 0$. So, we can easily see that, whenever $\mathbb{K}$ is open, (1.1.6) is automatically satisfied for the choice $\mathbb{V} = \mathbb{K}$. More than this, they prove that, in many situations, the condition above is even necessary for local invariance. The philosophy of this result rests on the simple observation that the local invariance is equivalent to the "$(\mathbb{D},\mathbb{K})$-separating uniqueness" property defined below, while (1.1.6) implies $(\mathbb{D},\mathbb{K})$-separating uniqueness and, even viability, if f is continuous. More precisely, we say that (1.1.1) has the $(\mathbb{D},\mathbb{K})$-*separating uniqueness property* if, for each $(\tau,\xi) \in \mathbb{I} \times \mathbb{D}$ and every solutions $u, v : [\tau, T] \to \mathbb{D}$ of (1.1.1), satisfying $u(\tau) = v(\tau) = \xi$, there exists $c \in (\tau, T]$ such that both $u([\tau,c))$ and $v([\tau,c))$ are included either in $\mathbb{D} \setminus \mathbb{K}$, or in $\mathbb{K}$. In fact, if f is continuous, the Nagumo's tangency condition (1.1.3) combined with $(\mathbb{D},\mathbb{K})$-separating uniqueness is nothing else than a simple rephrasing of the local invariance property. Indeed, *if* $\mathbb{K} \subseteq \mathbb{D} \subseteq \mathbb{R}^n$, *with* $\mathbb{K}$ *closed and* $\mathbb{D}$ *open, and* $f : \mathbb{I} \times \mathbb{D} \to \mathbb{R}^n$ *is continuous, then* $\mathbb{K}$ *is locally invariant with respect to* f *if and only if* (1.1.3) *is satisfied and* (1.1.1) *has the* $(\mathbb{D},\mathbb{K})$-*separating uniqueness property*.

Notations

$B(\xi,\rho)$ — the closed ball in $\mathbb{R}^n$ centered at ξ and of radius $\rho > 0$

$\mathcal{B}_{\mathbb{K}}(\xi)$ — the Bony's tangent cone to $\mathbb{K}$ at ξ

$\mathcal{C}_{\mathbb{K}}(\xi)$ — $\{\eta \in \mathbb{R}^n;\ \lim_{h\downarrow 0,\mu\to\xi} \frac{1}{h}\operatorname{dist}(\mu + h\eta;\mathbb{K}) = 0\}$, i.e. the Clarke's tangent cone to $\mathbb{K}$ at ξ

$\mathbb{D}$ — a domain, i.e. a nonempty and open subset in $\mathbb{R}^n$

$\frac{\mathrm{d}^+}{\mathrm{d}s}$ — the right derivative

$\operatorname{dist}(\xi;\mathbb{K})$ — $\inf\{\|\xi - \eta\|;\ \eta \in \mathbb{K}\}$, i.e. the distance between $\xi \in \mathbb{R}^n$ and $\mathbb{K} \subseteq \mathbb{R}^n$

$\mathcal{F}_{\mathbb{K}}(\xi)$ — $\{\eta \in \mathbb{R}^n;\ \lim_{h\downarrow 0} \frac{1}{h}\operatorname{dist}(\xi + h\eta;\mathbb{K}) = 0\}$, i.e. the Federer's tangent cone to $\mathbb{K}$ at ξ

$F_{\tau,\xi}$ — $\{(s,u(s));\ s \geqslant \tau,\ u \in \mathcal{S}(\tau,\xi)\}$

$F_{\tau,\xi}(t)$ — $\{u(t);\ u \in \mathcal{S}(\tau,\xi)\}$

$\mathbb{I}$ — a nonempty and open interval in $\mathbb{R}$

$\mathbb{J}$ — a nonempty and non-degenerate, i.e. with nonempty interior interval in $\mathbb{R}$

$\mathbb{K}$ — a nonempty subset in $\mathbb{R}^n$

$L^p(\mathbb{S};\mathbb{R}^n)$ — the space of all equivalence classes, with respect to the λ almost everywhere equality, of measurable functions from $\mathbb{S}$ to $\mathbb{R}^n$ whose norms are p-Lebesgue integrable over $\mathbb{S}$

$L^1_{\mathrm{loc}}(\mathbb{I})$ — the space of all equivalence classes, with respect to the λ almost everywhere equality, of measurable functions from $\mathbb{I}$ to $\mathbb{R}$ whose norms are Lebesgue integrable over each compact subset in $\mathbb{I}$

l.s.c. — lower semicontinuous

$\mathbb{N}$ — the set of natural numbers, i.e. $0, 1, \dots n, \dots$

$\mathbb{N}^*$ — the set of strictly positive natural numbers, i.e. $1, 2, \dots n, \dots$

$\mathcal{N}_{\mathbb{K}}(\xi)$ — the cone of normals in the sense of Bony to $\mathbb{K}$ at ξ

$(\mathcal{N}_{\mathbb{K}}(\xi))^*$	— the conjugate of $\mathcal{N}_{\mathbb{K}}(\xi)$, i.e. the set of all $\eta \in \mathbb{R}^n$ satisfying $\langle \eta, \nu \rangle \leqslant 0$ for each $\nu \in \mathcal{N}_{\mathbb{K}}(\xi)$
ν	— a vector which is normal in the sense of Bony to $\mathbb{K}$ at ξ
$\mathbb{R}^n$	— the linear space over $\mathbb{R}$ of all n-tuples of real numbers
$\mathbb{R}$	— the set of real numbers
$\overline{\mathbb{R}}$	— $\mathbb{R} \cup \{-\infty, +\infty\}$, i.e. the extended set of real numbers
$\mathcal{S}(\tau, \xi)$	— the set of all noncontinuable solutions u of $u'(t) = f(t, u(t))$ satisfying $u(\tau) = \xi$
$\mathcal{T}_{\mathbb{K}}(\xi)$	— $\{\eta \in \mathbb{R}^n;\ \liminf_{h \downarrow 0} \frac{1}{h} \operatorname{dist}(\xi + h\eta; \mathbb{K}) = 0\}$, i.e. the Bouligand–Severi's tangent cone to $\mathbb{K}$ at ξ
u.s.c.	— upper semicontinuous
$[x, y]_+$	— the right directional derivative of the norm calculated at x in the direction y

2. Preliminaries

2.1. *Brezis–Browder ordering principle*

The goal of this subsection is to prove a general and very simple principle concerning preorder relations which unifies a number of various results in nonlinear functional analysis, principle due to Brezis and Browder [19]. We notice that this is an ordering principle similar to Zorn's lemma, but based on the *axiom of dependent choice* which, as shown by Feferman [42], turns out to be strictly weaker than *the axiom of choice*. For easy reference we recall:

THE AXIOM OF DEPENDENT CHOICE. *Let $\mathcal{S}$ be a nonempty set and let $\mathcal{R} \subseteq \mathcal{S} \times \mathcal{S}$ be a binary relation with the property that, for each $\xi \in \mathcal{S}$, the set $\{\eta \in \mathcal{S};\ \xi \mathcal{R} \eta\}$ is nonempty. Then, for each $\xi \in \mathcal{S}$, there exists a sequence $(\xi_m)_m$ in $\mathcal{S}$ such that $\xi_0 = \xi$ and $\xi_m \mathcal{R} \xi_{m+1}$ for each $m \in \mathbb{N}$.*

We notice that, in its turn, the axiom of dependent choice implies *the axiom of countable choice* stated below, which is sufficient to prove that a lot of remarkable properties in Real Analysis can be described by means of sequences. We emphasize that the axiom of dependent choice is "far enough" from the axiom of countable choice, as shown recently by Howard and Rubin [57].

THE AXIOM OF COUNTABLE CHOICE. *Let $\mathcal{S}$ be a nonempty set and let $\mathcal{F} = \{\mathbb{F}_m;\ m \in \mathbb{N}\}$ be a countable family of nonempty subsets in $\mathcal{S}$. Then, there exists a sequence $(\xi_m)_m$ with the property that $\xi_m \in \mathbb{F}_m$ for each $m \in \mathbb{N}$.*

Finally, we notice that we preferred this framework simply because the results based on the axiom of dependent choice remain true no matter which initial assumption we make, i.e. no matter if we assume that either the axiom of choice, or its negation, holds true.

Let $\mathcal{S}$ be a nonempty set. A binary relation $\preceq \subseteq \mathcal{S} \times \mathcal{S}$ is a *preorder on $\mathcal{S}$* if it is reflexive, i.e. $\xi \preceq \xi$ for each $\xi \in \mathcal{S}$, and transitive, i.e. $\xi \preceq \eta$ and $\eta \preceq \zeta$ imply $\xi \preceq \zeta$.

DEFINITION 2.1.1. Let $\mathcal{S}$ be a nonempty set, $\preceq$ a preorder on $\mathcal{S}$ and let $\mathcal{M}:\mathcal{S}\to\mathbb{R}\cup\{+\infty\}$ be an increasing function. An *$\mathcal{M}$-maximal element* is an element $\bar{\xi}\in\mathcal{S}$ satisfying $\mathcal{M}(\xi)=\mathcal{M}(\bar{\xi})$, for every $\xi\in\mathcal{S}$ with $\bar{\xi}\preceq\xi$.

THEOREM 2.1.1 (Brezis–Browder ordering principle [19]). *Let $\mathcal{S}$ be a nonempty set, $\preceq$ a preorder on $\mathcal{S}$ and let $\mathcal{M}:\mathcal{S}\to\mathbb{R}\cup\{+\infty\}$ be a function. Suppose that*:

(i) *for any increasing sequence $(\xi_k)_k$ in $\mathcal{S}$, there exists some $\eta\in\mathcal{S}$ such that $\xi_k\preceq\eta$ for all $k\in\mathbb{N}$;*

(ii) *the function $\mathcal{M}$ is increasing.*

Then, for each $\xi_0\in\mathcal{S}$ there exists an $\mathcal{M}$-maximal element $\bar{\xi}\in\mathcal{S}$ satisfying $\xi_0\preceq\bar{\xi}$.

PROOF. Suppose first that the function $\mathcal{M}$ is bounded from above. Let us consider a fixed element $\xi_0\in\mathcal{S}$ and let us construct (inductively) an increasing sequence $(\xi_k)_k$ as follows: if ξ_k is given, let us consider the set $\mathcal{S}_k=\{\xi\in\mathcal{S};\ \xi_k\preceq\xi\}$ and let us denote by $\beta_k=\sup\{\mathcal{M}(\xi);\ \xi\in\mathcal{S}_k\}$. If ξ_k satisfies the conclusion, we have nothing to prove. If not, then $\beta_k>\mathcal{M}(\xi_k)$, and so we get ξ_{k+1} such that $\xi_k\preceq\xi_{k+1}$ and

$$\mathcal{M}(\xi_{k+1})>\beta_k-\frac{\beta_k-\mathcal{M}(\xi_k)}{2}. \tag{2.1.1}$$

We have thus constructed an increasing sequence (here is the point where we have used the axiom of dependent choices) $(\xi_k)_k$ with the property that the sequence $(\mathcal{M}(\xi_k))_k$ is strictly increasing. By the assumption (i), $(\xi_k)_k$ is bounded above in $\mathcal{S}$, i.e., there exists $\bar{\xi}\in\mathcal{S}$ such that $\xi_k\preceq\bar{\xi}$ for every $k\in\mathbb{N}$. We show that this $\bar{\xi}$ satisfies the conclusion. Suppose by contradiction that there exists $\eta\in\mathcal{S}$ such that $\bar{\xi}\preceq\eta$ and $\mathcal{M}(\bar{\xi})<\mathcal{M}(\eta)$. Since $\mathcal{M}$ is bounded from above, the sequence $(\mathcal{M}(\xi_k))_k$ is bounded from above, and thus convergent. Moreover $\lim_{k\to\infty}\mathcal{M}(\xi_k)\leqslant\mathcal{M}(\bar{\xi})$ and $\eta\in\mathcal{S}_k$ for each $k\in\mathbb{N}$. Therefore we have $\beta_k\geqslant\mathcal{M}(\eta)$. From (2.1.1), we deduce

$$2\mathcal{M}(\xi_{k+1})-\mathcal{M}(\xi_k)\geqslant\beta_k\geqslant\mathcal{M}(\eta),$$

for all $k\in\mathbb{N}$. Passing to the limit as $k\to\infty$, we obtain $\mathcal{M}(\bar{\xi})\geqslant\mathcal{M}(\eta)$, which is a contradiction. This achieves the proof under the extra-condition that $\mathcal{M}$ is bounded above.

Consider now the general case, and let us define the auxiliary function $\mathcal{M}_1:\mathcal{S}\to(-\frac{\pi}{2},\frac{\pi}{2}]$ by

$$\mathcal{M}_1(\xi)=\begin{cases}\arctan\bigl(\mathcal{M}(\xi)\bigr) & \text{if } \mathcal{M}(\xi)<+\infty,\\ \dfrac{\pi}{2} & \text{if } \mathcal{M}(\xi)=+\infty.\end{cases}$$

The function $\mathcal{M}_1$ is increasing and bounded from above. Therefore there exists an element $\bar{\xi}\in\mathcal{S}$ which verifies the conclusion with $\mathcal{M}_1$ instead of $\mathcal{M}$. But $\arctan\mathcal{M}(\bar{\xi})=\arctan\mathcal{M}(\xi)$ implies $\mathcal{M}(\bar{\xi})=\mathcal{M}(\xi)$, which completes the proof in the general case. □

In its original formulation of Brezis–Browder ordering principle, it is assumed that $\mathcal{M}$ is bounded from above. In order to handle a larger class of applications this condition has been dropped in Cârjă and Ursescu [25], by obtaining the very slight extension here presented. A simple inspection of the proof shows that the conclusion of Theorem 2.1.1 remains true if (i) is replaced by the weaker condition:

(j) *For any increasing sequence* $(\xi_k)_k$ *in* $\mathcal{S}$ *with the property that the sequence* $(\mathcal{M}(\xi_k))_k$ *is strictly increasing, there exists some* $\eta \in \mathcal{S}$ *such that* $\xi_k \preceq \eta$ *for all* $k \in \mathbb{N}$.

2.2. *Projections*

We begin with:

DEFINITION 2.2.1. A subset $\mathbb{K} \subseteq \mathbb{R}^n$ is *locally closed* if for every $\xi \in \mathbb{K}$ there exists $\rho > 0$ such that $\mathbb{K} \cap B(\xi, \rho)$ is closed.

REMARK 2.2.1. Obviously every closed set is locally closed. Furthermore, if $\mathbb{D}$ is a given open subset in $\mathbb{R}^n$, then every relatively closed subset $\mathbb{K}$ in $\mathbb{D}$ is locally closed too. Indeed, if $\mathbb{K}$ is relatively closed, then $\mathbb{K} = \overline{\mathbb{K}} \cap \mathbb{D}$ and so, for every $\xi \in \mathbb{K}$ there exists $\rho > 0$ such that $B(\xi, \rho) \subseteq \mathbb{D}$. Consequently $\mathbb{K} \cap B(\xi, \rho) = \overline{\mathbb{K}} \cap \mathbb{D} \cap B(\xi, \rho) = \overline{\mathbb{K}} \cap B(\xi, \rho)$ which is closed, and this proves the assertion. Thus, each open subset $\mathbb{K}$ in $\mathbb{R}^n$ is locally closed. There exist however locally closed sets which are neither open, nor closed, nor even closed relatively to $\mathbb{D}$, as for example $\mathbb{K} \subseteq \mathbb{D} \subseteq \mathbb{R}^2$ defined by $\mathbb{D} = \{(x, y) \in \mathbb{R}^2;\ x > 0\}$ and $\mathbb{K} = \{(x, y) \in \mathbb{R}^2;\ 0 < x < 1, y = 0\}$. The set $\mathbb{K}$, which is in fact a line segment in the plane xOy, is locally closed but is neither open, nor closed, nor even closed relatively to $\mathbb{D}$.

We say that $\xi \in \mathbb{R}^n$ *has projection on* $\mathbb{K}$ if there exists $\eta \in \mathbb{K}$ such that $\|\xi - \eta\| = \operatorname{dist}(\xi; \mathbb{K})$. Any $\eta \in \mathbb{K}$ enjoying the above property is called *a projection* of ξ on $\mathbb{K}$, and the set of all projections of ξ on $\mathbb{K}$ is denoted by $\Pi_{\mathbb{K}}(\xi)$.

DEFINITION 2.2.2. An open neighborhood $\mathbb{V}$ of $\mathbb{K}$, with $\Pi_{\mathbb{K}}(\xi) \neq \emptyset$ for each $\xi \in \mathbb{V}$, is called a *proximal neighborhood* of $\mathbb{K}$. If $\mathbb{V}$ is a proximal neighborhood of $\mathbb{K}$, then every single-valued selection, $\pi_{\mathbb{K}} : \mathbb{V} \to \mathbb{K}$, of $\Pi_{\mathbb{K}}$, i.e. $\pi_{\mathbb{K}}(\xi) \in \Pi_{\mathbb{K}}(\xi)$ for each $\xi \in \mathbb{V}$, is a *projection subordinated to* $\mathbb{V}$.

The next lemma, proved in Cârjă and Ursescu [25, Lemma 18], shows that for each locally closed set $\mathbb{K}$, all the points which are sufficiently close to $\mathbb{K}$ do have projections, i.e. each locally closed set $\mathbb{K}$ has one proximal neighborhood.

LEMMA 2.2.1. *Let* $\mathbb{K}$ *be locally closed. Then the set of all* $\xi \in \mathbb{R}^n$ *such that* $\Pi_{\mathbb{K}}(\xi)$ *is nonempty is a neighborhood of* $\mathbb{K}$.

PROOF. Let $\xi \in \mathbb{K}$. Since $\mathbb{K}$ is locally closed, there exists $\rho > 0$ such that $\mathbb{K} \cap B(\xi, \rho)$ is closed. To complete the proof, it suffices to show that, for each $\eta \in \mathbb{K}$ satisfying $\|\xi - \eta\| < \rho/2$, $\Pi_{\mathbb{K}}(\eta)$ is nonempty. Indeed, for each η as above, there exists a sequence $(\zeta_k)_k$ in $\mathbb{K}$ such that $(\|\zeta_k - \eta\|)_k$ converges to $\operatorname{dist}(\eta; \mathbb{K})$. We can suppose, by taking a subsequence if necessary, that $(\zeta_k)_k$ converges to a point $\zeta \in \mathbb{R}^n$. So, we have $\operatorname{dist}(\eta; \mathbb{K}) = \|\zeta - \eta\|$. Clearly, $\|\zeta_k - \xi\| \leqslant \|\zeta_k - \eta\| + \|\eta - \xi\|$ for all $k \in \mathbb{N}$, and consequently $\|\zeta - \xi\| \leqslant \operatorname{dist}(\eta; \mathbb{K}) + \|\eta - \xi\| \leqslant 2\|\eta - \xi\| < \rho$. Finally, $\|\zeta_k - \eta\| < \rho$ for all $k \in \mathbb{N}$ sufficiently large. Therefore $\zeta_k \in \mathbb{K} \cap B(\xi, \rho)$, and since the latter is closed, it follows that $\zeta \in \mathbb{K}$. Thus $\Pi_{\mathbb{K}}(\eta)$ is nonempty, and this completes the proof. □

2.3. *Tangent cones*

The next tangency concept was introduced independently by Bouligand [16] and Severi [89].

DEFINITION 2.3.1. Let $\mathbb{K} \subseteq \mathbb{R}^n$ and $\xi \in \mathbb{K}$. The vector $\eta \in \mathbb{R}^n$ is *tangent in the sense of Bouligand–Severi* to the set $\mathbb{K}$ at the point ξ if

$$\liminf_{h \downarrow 0} \frac{1}{h} \operatorname{dist}(\xi + h\eta; \mathbb{K}) = 0.$$

PROPOSITION 2.3.1. *The set $\mathcal{T}_{\mathbb{K}}(\xi)$ of all vectors which are tangent in the sense of Bouligand–Severi to the set $\mathbb{K}$ at the point ξ is a closed cone.*

PROOF. Let $\xi \in \mathbb{K}$. According to Definition 2.3.1, $\eta \in \mathcal{T}_{\mathbb{K}}(\xi)$ if

$$\liminf_{t \downarrow 0} \frac{1}{t} \operatorname{dist}(\xi + t\eta; \mathbb{K}) = 0.$$

Let $s > 0$ and let us observe that

$$\begin{aligned} \liminf_{t \downarrow 0} \frac{1}{t} \operatorname{dist}(\xi + ts\eta; \mathbb{K}) &= s \liminf_{t \downarrow 0} \frac{1}{ts} \operatorname{dist}(\xi + ts\eta; \mathbb{K}) \\ &= s \liminf_{\tau \downarrow 0} \frac{1}{\tau} \operatorname{dist}(\xi + \tau\eta; \mathbb{K}) = 0. \end{aligned}$$

Hence $s\eta \in \mathcal{T}_{\mathbb{K}}(\xi)$. In order to complete the proof, it remains to show that $\mathcal{T}_{\mathbb{K}}(\xi)$ is a closed set. To this aim let $(\eta_k)_{k \in \mathbb{N}^*}$ be a sequence of elements in $\mathcal{T}_{\mathbb{K}}(\xi)$, convergent to η. We have

$$\begin{aligned} \frac{1}{t} \operatorname{dist}(\xi + t\eta; \mathbb{K}) &\leqslant \frac{1}{t} \left\| t(\eta - \eta_k) \right\| + \frac{1}{t} \operatorname{dist}(\xi + t\eta_k; \mathbb{K}) \\ &= \|\eta - \eta_k\| + \frac{1}{t} \operatorname{dist}(\xi + t\eta_k; \mathbb{K}) \end{aligned}$$

for every $k \in \mathbb{N}^*$. So $\liminf_{t \downarrow 0} \frac{1}{t} \operatorname{dist}(\xi + t\eta; \mathbb{K}) \leqslant \|\eta - \eta_k\|$ for every $k \in \mathbb{N}^*$. Since $\lim_{k \to \infty} \|\eta - \eta_k\| = 0$, it follows that $\liminf_{t \downarrow 0} \frac{1}{t} \operatorname{dist}(\xi + t\eta; \mathbb{K}) = 0$, which achieves the proof. □

Following Bouligand [16], the cone $\mathcal{T}_{\mathbb{K}}(\xi)$ is called *the contingent cone* to the set $\mathbb{K}$ at the point ξ.

PROPOSITION 2.3.2. *A vector $\eta \in \mathbb{R}^n$ belongs to the cone $\mathcal{T}_{\mathbb{K}}(\xi)$ if and only if for every $\varepsilon > 0$ there exist $h \in (0, \varepsilon)$ and $p_h \in B(0, \varepsilon)$ with the property*

$$\xi + h(\eta + p_h) \in \mathbb{K}.$$

PROOF. Obviously $\eta \in \mathcal{T}_{\mathbb{K}}(\xi)$ if and only if, for every $\varepsilon > 0$ there exists $h \in (0, \varepsilon)$ and $z_h \in \mathbb{K}$ such that $\frac{1}{h}\|\xi + h\eta - z_h\| \leqslant \varepsilon$. Now, let us define $p_h = \frac{1}{h}(z_h - \xi - h\eta)$, and let us observe that we have both $\|p_h\| \leqslant \varepsilon$, and $\xi + h(\eta + p_h) = z_h \in \mathbb{K}$, thereby completing the proof. □

A simple but useful consequence is:

COROLLARY 2.3.1. *A vector $\eta \in \mathbb{R}^n$ belongs to the cone $\mathcal{T}_{\mathbb{K}}(\xi)$ if and only if there exist two sequences $(h_m)_m$ in $\mathbb{R}_+$ and $(p_m)_m$ in $\mathbb{R}^n$ with $h_m \downarrow 0$ and $p_m \to 0$ as $m \to \infty$, and such that $\xi + h_m(\eta + p_m) \in \mathbb{K}$ for each $m \in \mathbb{N}$.*

REMARK 2.3.1. We notice that, if ξ is an interior point of the set $\mathbb{K}$, then $\mathcal{T}_{\mathbb{K}}(\xi) = \mathbb{R}^n$. Indeed, in this case there exists $\rho > 0$ such that $B(\xi, \rho) \subset \mathbb{K}$ and, therefore, for $t > 0$ sufficiently small, $\xi + t\eta \in B(\xi, \rho) \subseteq \mathbb{K}$. Obviously, for such numbers $t > 0$, we have $\operatorname{dist}(\xi + t\eta; \mathbb{K}) = 0$, from where it follows the condition in Definition 2.3.1.

An interesting consequence of Corollary 2.3.1 is given below.

THEOREM 2.3.1. *Let $\mathbb{K}_1, \mathbb{K}_2 \subseteq \mathbb{R}^n$ be locally closed. If $\xi \in \mathbb{K}_1 \cap \mathbb{K}_2$ is an interior point of $\mathbb{K}_1 \cup \mathbb{K}_2$, then we have*

$$\mathcal{T}_{\mathbb{K}_1 \cap \mathbb{K}_2}(\xi) = \mathcal{T}_{\mathbb{K}_1}(\xi) \cap \mathcal{T}_{\mathbb{K}_2}(\xi).$$

PROOF. Obviously, for each $\xi \in \mathbb{K}_1 \cap \mathbb{K}_2$, $\mathcal{T}_{\mathbb{K}_1 \cap \mathbb{K}_2}(\xi) \subseteq \mathcal{T}_{\mathbb{K}_1}(\xi) \cap \mathcal{T}_{\mathbb{K}_2}(\xi)$. To prove that, whenever, in addition, ξ is in the interior of $\mathbb{K}_1 \cup \mathbb{K}_2$, the converse inclusion holds true, let $\xi \in \mathbb{K}_1 \cap \mathbb{K}_2$ and let $\eta \in \mathcal{T}_{\mathbb{K}_1}(\xi) \cap \mathcal{T}_{\mathbb{K}_2}(\xi)$. By Corollary 2.3.1, there exist four sequences $(h_m)_m$, $(\tilde{h}_m)_m$ in $\mathbb{R}_+$, $(p_m)_m$ and $(\tilde{p}_m)_m$ in X with $h_m \downarrow 0$, $\tilde{h}_m \downarrow 0$, $p_m \to 0$ and $\tilde{p}_m \to 0$ as $m \to \infty$, and such that $\xi + h_m(\eta + p_m) \in \mathbb{K}_1$ and $\xi + \tilde{h}_m(\eta + \tilde{p}_m) \in \mathbb{K}_2$ for each $m \in \mathbb{K}$. Now, if we assume further that ξ is in the interior of $\mathbb{K}_1 \cup \mathbb{K}_2$, there exists $\rho > 0$ such that $B(\xi, \rho) \subset \mathbb{K}_1 \cup \mathbb{K}_2$. Since $\mathbb{K}_1$ and $\mathbb{K}_2$ are locally closed, diminishing $\rho > 0$ if necessary, we may assume that both $\mathbb{K}_1 \cap B(\xi, \rho)$ and $\mathbb{K}_2 \cap B(\xi, \rho)$ are closed. Let $m_0 \in \mathbb{N}$ be such that, for each $m \geqslant m_0$, we have both $\xi_m = \xi + h_m(\eta + p_m) \in B(\xi, \rho)$ and $\tilde{\xi}_m = \xi + \tilde{h}_m(\eta + \tilde{p}_m) \in B(\xi, \rho)$. As a consequence, if $m \geqslant m_0$, the line segment $[\xi_m, \tilde{\xi}_m] \subseteq B(\xi, \rho) \subseteq \mathbb{K}_1 \cup \mathbb{K}_2$. Since $B(\xi, \rho)$ is connected, while $B(\xi, \rho) \cap \mathbb{K}_1$ and $B(\xi, \rho) \cap \mathbb{K}_2$ are closed, there exists $\eta_m \in [\xi_m, \tilde{\xi}_m] \cap \mathbb{K}_1 \cap \mathbb{K}_2$. Since $\eta_m \in [\xi_m, \tilde{\xi}_m]$, there exists $\theta_m \in [0, 1]$ such that $\eta_m = (1 - \theta_m)\xi_m + \theta_m \tilde{\xi}_m$. So, denoting

$$t_m = (1 - \theta_m)h_m + \theta_m \tilde{h}_m \quad \text{and} \quad q_m = \frac{(1 - \theta_m)h_m}{t_m} p_m + \frac{\theta_m \tilde{h}_m}{t_m} \tilde{p}_m,$$

we have

$$\eta_m = \xi + t_m(\eta + q_m) \in \mathbb{K}_1 \cap \mathbb{K}_2.$$

Finally, observing that $t_m \downarrow 0$ and $q_m \to 0$, and using Corollary 2.3.1, we get the conclusion. □

In the case when $\mathbb{K}_1, \mathbb{K}_2$ are closed subsets in a normed vector space, a similar result was obtained by Quincampoix [84, Corollary 2.3].

The next tangency concept was introduced by Federer [41]. See also Girsanov [49].

DEFINITION 2.3.2. Let $\mathbb{K} \subseteq \mathbb{R}^n$ and $\xi \in \mathbb{K}$. The vector $\eta \in \mathbb{R}^n$ is *tangent in the sense of Federer* to the set $\mathbb{K}$ at the point ξ if

$$\lim_{h \downarrow 0} \frac{1}{h} \operatorname{dist}(\xi + h\eta; \mathbb{K}) = 0.$$

The set of all points $\eta \in \mathbb{R}^n$ which are tangent in the sense of Federer to $\mathbb{K}$ at ξ is denoted by $\mathcal{F}_{\mathbb{K}}(\xi)$. This set is a cone which clearly is included in $\mathcal{T}_{\mathbb{K}}(\xi)$. A not necessarily metrical tangency concept in general topological vector spaces which, in $\mathbb{R}^n$, reduces to that one of Federer [41], is due to Ursescu [95]. As we shall show next, for a continuous function $f : \mathbb{K} \to \mathbb{R}^n$, the following surprising equivalence holds true: $f(\xi) \in \mathcal{T}_{\mathbb{K}}(\xi)$ for each $\xi \in \mathbb{K}$ if and only if $f(\xi) \in \mathcal{F}_{\mathbb{K}}(\xi)$ for each $\xi \in \mathbb{K}$, and this in spite of the fact that $\mathcal{F}_{\mathbb{K}}(\xi) \neq \mathcal{T}_{\mathbb{K}}(\xi)$.

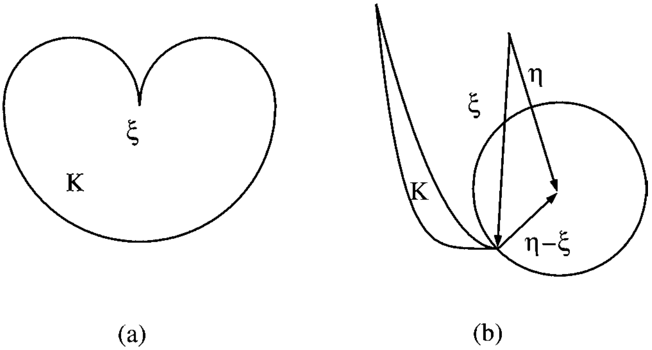
2.4. *The proximal normal cone*

We begin by recalling:

DEFINITION 2.4.1. Let $\xi \in \mathbb{K}$. We say that $\nu \in \mathbb{R}^n$ is *metric normal to* $\mathbb{K}$ *at* ξ, if there exist $\eta \in \mathbb{R}^n$ and $\rho > 0$ such that $B(\eta, \rho)$ contains ξ on its boundary, its interior has empty intersection with $\mathbb{K}$, and $\nu = \eta - \xi$.

In Fig. 1(a) is illustrated a point ξ at which there is no metric normal vector. We notice that we have $\mathcal{T}_{\mathbb{K}}(\xi) = \mathbb{R}^n$. For the case in which there is at least one normal vector to $\mathbb{K}$ at a point ξ, see Fig. 1(b).

DEFINITION 2.4.2. The *proximal normal cone to* $\mathbb{K}$ *at* $\xi \in \mathbb{K}$ is the set of all $\zeta \in \mathbb{R}^n$ of the form $\zeta = \lambda\nu$, where ν is metric normal to $\mathbb{K}$ at ξ and $\lambda \geqslant 0$, whenever such a metric normal ν exists, and $\{0\}$ if there is no metric normal to $\mathbb{K}$ at ξ. We denote this cone by $\mathcal{N}_{\mathbb{K}}(\xi)$.



(a) (b)

Fig. 1.

The use of the term "cone" in Definition 2.4.2, is justified by the simple observation that, for each $\xi \in \mathbb{K}$, $\mathcal{N}_{\mathbb{K}}(\xi)$ is a cone in the usual sense, i.e., for each $\zeta \in \mathcal{N}_{\mathbb{K}}(\xi)$ and $\lambda > 0$, we have $\lambda\zeta \in \mathcal{N}_{\mathbb{K}}(\xi)$.

The next tangency concept was introduced by Ursescu [101]. Let now $\mathbb{S}_{\mathbb{K}}(\xi)$ be the set of all $\eta \in \mathbb{R}^n$ such that $\eta - \xi$ is a metric normal to $\mathbb{K}$ at ξ whenever such a metric normal exists, and $\mathbb{S}_{\mathbb{K}}(\xi) = \{\xi\}$ otherwise. Let $\eta \in \mathbb{S}_{\mathbb{K}}(\xi)$, and let $\mathbb{E}(\xi, \eta) = \{\zeta \in \mathbb{R}^n;\ \|\eta - \zeta\| \geqslant \|\eta - \xi\|\}$. Since $\mathbb{K} \subseteq \mathbb{E}(\xi, \eta)$, for each $\eta \in \mathcal{S}_{\mathbb{K}}(\xi)$, we have

$$\mathcal{T}_{\mathbb{K}}(\xi) \subseteq \mathcal{B}_{\mathbb{K}}(\xi), \tag{2.4.1}$$

where

$$\mathcal{B}_{\mathbb{K}}(\xi) = \bigcap_{\eta \in \mathbb{S}_{\mathbb{K}}(\xi)} \mathcal{T}_{\mathbb{E}(\xi,\eta)}(\xi).$$

One may easily see that $\mathcal{B}_{\mathbb{K}}(\xi)$ is a cone in $\mathbb{R}^n$.

DEFINITION 2.4.3. The set $\mathcal{B}_{\mathbb{K}}(\xi)$, defined as above, is the *Bony tangent cone to* $\mathbb{K}$ *at* ξ, and its elements are the *tangents in the sense of Bony* to $\mathbb{K}$ at $\xi \in \mathbb{K}$.

Let $\|\cdot\|$ be a given norm on $\mathbb{R}^n$. If $x, y \in \mathbb{R}^n$, we denote by $[x, y]_+$ the *right directional derivative of the norm* calculated at x in the direction y, i.e.

$$[x, y]_+ = \lim_{h \downarrow 0} \frac{\|x + hy\| - \|x\|}{h}.$$

If $\|\cdot\|$ is the Euclidean norm, we have

$$[x, y]_+ = \begin{cases} \dfrac{\langle x, y\rangle}{\|x\|} & \text{if } x \neq 0, \\ \|y\| & \text{if } x = 0. \end{cases}$$

REMARK 2.4.1. Taking into account the definitions of both $\mathbb{E}(\xi,\eta)$ and $[\cdot,\cdot]_+$, we easily deduce that $\zeta \in \mathcal{T}_{\mathbb{E}(\xi,\eta)}(\xi)$ if and only if $[\xi-\eta,\zeta]_+ \geqslant 0$. Therefore, $\zeta \in \mathcal{B}_{\mathbb{K}}(\xi)$ if and only if $[-\nu,\zeta]_+ \geqslant 0$ for each ν which is a metric normal to $\mathbb{K}$ at ξ. In particular, when $\mathbb{R}^n$ is endowed with the Euclidean norm, we easily deduce that, for each $\xi \in \mathbb{K}$ and each $\eta \in \mathbb{S}_{\mathbb{K}}(\xi)$, $\mathcal{T}_{\mathbb{E}(\xi,\eta)}(\xi)$ is a closed half-space having the exterior normal $\eta-\xi$. Therefore, in this case, we have

$$\mathcal{B}_{\mathbb{K}}(\xi) = \big(\mathcal{N}_{\mathbb{K}}(\xi)\big)^*,$$

where $(\mathcal{N}_{\mathbb{K}}(\xi))^*$ is the so-called *conjugate cone* of $\mathcal{N}_{\mathbb{K}}(\xi)$, i.e.

$$\big(\mathcal{N}_{\mathbb{K}}(\xi)\big)^* = \big\{\eta \in \mathbb{R}^n;\ \langle \nu,\eta\rangle \leqslant 0,\ \text{for each } \nu \in \mathcal{N}_{\mathbb{K}}(\xi)\big\}.$$

REMARK 2.4.2. If there is no metric normal vector to $\mathbb{K}$ at ξ, we may easily see that $\mathcal{B}_{\mathbb{K}}(\xi) = \mathbb{R}^n$. See also Fig. 1(a).

2.5. *Clarke's tangent cone*

We are now ready to study another useful tangency concept defined by Clarke [32].

DEFINITION 2.5.1. Let $\mathbb{K} \subseteq \mathbb{R}^n$ and $\xi \in \mathbb{K}$. The vector $\eta \in \mathbb{R}^n$ is *tangent in the sense of Clarke* to the set $\mathbb{K}$ at the point ξ if

$$\lim_{\substack{h\downarrow 0\\ \mu\to\xi;\,\mu\in\mathbb{K}}} \frac{1}{h}\,\mathrm{dist}(\mu+h\eta;\mathbb{K}) = 0.$$

We denote by $\mathcal{C}_{\mathbb{K}}(\xi)$ the set of all vectors $\eta \in \mathbb{R}^n$ which are tangent to $\xi \in \mathbb{K}$ in the sense of Clarke. It is not difficult to check out that $\mathcal{C}_{\mathbb{K}}(\xi)$ is a closed convex cone.

REMARK 2.5.1. One may easily see that, for each $\mathbb{K}$ and each $\xi \in \mathbb{K}$, we have

$$\mathcal{C}_{\mathbb{K}}(\xi) \subseteq \mathcal{F}_{\mathbb{K}}(\xi) \subseteq \mathcal{T}_{\mathbb{K}}(\xi) \subseteq \mathcal{B}_{\mathbb{K}}(\xi).$$

We notice that, whenever $\mathbb{K}$ admits a classical tangent space at $\xi \in \mathbb{K}$, all tangent cones previously introduced coincide with that tangent space. This happens for instance if $\mathbb{K}$ is a C^1 curve, or surface or, even if $\mathbb{K}$ is an m-dimensional C^1 manifold. However, if $\mathbb{K}$ is not smooth enough locally around ξ, the inclusions $\mathcal{C}_{\mathbb{K}}(\xi) \subseteq \mathcal{C}_{\mathbb{K}}(\xi) \subseteq \mathcal{T}_{\mathbb{K}}(\xi) \subseteq \mathcal{B}_{\mathbb{K}}(\xi)$ may be strict, as the following example shows.

EXAMPLE 2.5.1 (Necula [73]). Let $\mathbb{K} \subseteq \mathbb{R}^2$ be defined as $\mathbb{K} = \mathbb{K}_1 \cup \mathbb{K}_2$, where

$$\mathbb{K}_1 = \big\{(x,y);\ (x,y) \in \mathbb{R}^2,\ y \leqslant |x|\big\}$$

and

$$\mathbb{K}_2 = \left\{ \left(0, 1/2^m\right);\ m \in \mathbb{N} \right\}$$

and let $\xi = (0, 0) \in \mathbb{K}$. Then, we have

$$\begin{cases} \mathcal{C}_{\mathbb{K}}(\xi) = \{0\}, \\ \mathcal{F}_{\mathbb{K}}(\xi) = \mathbb{K}_1, \\ \mathcal{T}_{\mathbb{K}}(\xi) = \mathbb{K}_1 \cup \left\{(0, y);\ y \geqslant 0\right\}, \\ \mathcal{B}_{\mathbb{K}}(\xi) = \mathbb{R}^2. \end{cases}$$

For a multifunction[2] $F : \mathbb{K} \rightsquigarrow \mathbb{R}^n$, we define

$$\liminf_{\substack{\xi \to \xi_0 \\ \xi \in \mathbb{K}}} F(\xi) = \left\{ \eta \in \mathbb{R}^n;\ \lim_{\substack{\xi \to \xi_0 \\ \xi \in \mathbb{K}}} \operatorname{dist}\bigl(\eta, F(\xi)\bigr) = 0 \right\}.$$

LEMMA 2.5.1. *Let us assume that the norm* $\|\cdot\|$ *on* $\mathbb{R}^n$ *satisfies*

$$[x, y]_+ = -[-x, y]_+$$

for each $x, y \in \mathbb{R}^n$.[3] *Let* $\mathbb{K} \subseteq \mathbb{R}^n$ *be locally closed. Then, for each* $\xi_0 \in \mathbb{K}$, *we have*

$$\liminf_{\xi \to \xi_0; \xi \in \mathbb{K}} \mathcal{B}_{\mathbb{K}}(\xi) = \mathcal{C}_{\mathbb{K}}(\xi_0). \tag{2.5.1}$$

PROOF. We begin by showing that

$$\liminf_{\xi \to \xi_0; \xi \in \mathbb{K}} \mathcal{B}_{\mathbb{K}}(\xi) \subseteq \mathcal{C}_{\mathbb{K}}(\xi_0). \tag{2.5.2}$$

Let $\eta \neq 0$, $\eta \in \liminf_{\xi \to \xi_0; \xi \in \mathbb{K}} \mathcal{B}_{\mathbb{K}}(\xi)$. It follows that, for each $\varepsilon > 0$, there exists $\theta > 0$ such that, for each $\phi \in \mathbb{K} \cap B(\xi_0, \theta)$, we have

$$B(\eta, \varepsilon) \cap \mathcal{B}_{\mathbb{K}}(\phi) \neq \emptyset. \tag{2.5.3}$$

Take a sufficiently small θ so that, for all $\xi \in \mathbb{K} \cap B(\xi_0, \frac{\theta}{4})$ and $t \in [0, \frac{\theta}{4\|\eta\|}]$, we have $\Pi_{\mathbb{K}}(\xi + t\eta) \neq \emptyset$. By virtue of Lemma 2.2.1, this is always possible. With ξ and t as above, let us define $g(t) = \operatorname{dist}(\xi + t\eta; \mathbb{K})$. In order to prove that $\eta \in \mathcal{C}_{\mathbb{K}}(\xi_0)$, it suffices to show that $g(t) \leqslant \varepsilon t$ for each $t \in [0, \frac{\theta}{4\|\eta\|}]$. Further, since $g(0) = 0$, it suffices to show that $g'(t) \leqslant \varepsilon$, whenever $g'(t)$ exists. To this aim, take $\phi \in \Pi_{\mathbb{K}}(\xi + t\eta)$, and let us observe that we have $\phi \in \mathbb{K} \cap B(\xi_0, \theta)$. Indeed,

$$\|\phi - \xi_0\| \leqslant \|\xi + t\eta - \phi\| + \|\xi + t\eta - \xi_0\| \leqslant 2\|\xi + t\eta - \xi_0\| \leqslant \theta,$$

---

[2] A function $F : \mathbb{K} \to \mathcal{P}(\mathbb{R}^n)$, where $\mathcal{P}(\mathbb{R}^n)$ is the class of all subsets of $\mathbb{R}^n$, is called *multifunction* and is denoted by $F : \mathbb{K} \rightsquigarrow \mathbb{R}^n$.

[3] This happens if $\|\cdot\|$ is Gâteaux differentiable.

as claimed. Now, for a sufficiently small $h > 0$, we obtain

$$g(t+h) - g(t) \leqslant \|\xi + t\eta + h\eta - \phi\| - \|\xi + t\eta - \phi\|.$$

Dividing by h and letting $h \downarrow 0$, we get

$$g'(t) \leqslant [\xi + t\eta - \phi, \eta]_+. \tag{2.5.4}$$

Taking into account that $\phi \in \Pi_{\mathbb{K}}(\xi + t\eta)$, from Definition 2.4.1, we deduce that $\xi + t\eta - \phi$ is metric normal to $\mathbb{K}$ at ϕ. In view of (2.5.3), there exists $w \in \mathcal{B}_{\mathbb{K}}(\phi)$ with $\|w - \eta\| \leqslant \varepsilon$. From Remark 2.4.1, we conclude

$$[-\xi - t\eta + \phi, w]_+ \geqslant 0.$$

According to the hypothesis, we have

$$[\xi + t\eta - \phi, \eta]_+ \leqslant [\xi + t\eta - \phi, \eta - w]_+ + [\xi + t\eta - \phi, w]_+ \leqslant \varepsilon.$$

From this inequality and (2.5.4), we get $g'(t) \leqslant \varepsilon$, as claimed. Thus (2.5.2) holds. Since $\mathcal{T}_{\mathbb{K}}(\xi) \subseteq \mathcal{B}_{\mathbb{K}}(\xi)$, to complete the proof, it suffices to show that

$$\mathcal{C}_{\mathbb{K}}(\xi_0) \subseteq \liminf_{\xi \to \xi_0; \xi \in \mathbb{K}} \mathcal{T}_{\mathbb{K}}(\xi).$$

So, let $\eta \in \mathcal{C}_{\mathbb{K}}(\xi_0)$ and let $\xi_m \in \mathbb{K}$ with $\xi_m \to \xi_0$. The idea is to find $\eta_m \in \mathcal{T}_{\mathbb{K}}(\xi_m)$ with $\eta_m \to \eta$. This would imply that $\eta \in \liminf_{\xi \to \xi_0; \xi \in \mathbb{K}} \mathcal{T}_{\mathbb{K}}(\xi)$. To this end, let us observe that, since $\eta \in \mathcal{C}_{\mathbb{K}}(\xi_0)$, for every $\varepsilon > 0$, there exist $m_\varepsilon \in \mathbb{N}$ and $h_\varepsilon > 0$ such that, for all $0 < h < h_\varepsilon$ and $m \geqslant m_\varepsilon$, we have

$$\operatorname{dist}(\xi_m + h\eta; \mathbb{K}) < h\varepsilon.$$

Fix m as above and take $\mu_m^h \in \mathbb{K}$ with $\|\mu_m^h - \xi_m - h\eta\| < h\varepsilon$. Let us consider

$$\eta_m^h = \frac{1}{h}\big(\mu_m^h - \xi_m\big).$$

Since $\|\eta_m^h - \eta\| \leqslant \varepsilon$, $\{\eta_m^h;\ h < 0 < h_\varepsilon\}$ is bounded and therefore it has a limit point η_m as $h \downarrow 0$. In its turn, η_m satisfies $\|\eta_m - \eta\| \leqslant \varepsilon$. A simple computational argument shows that $\eta_m \in \mathcal{T}_{\mathbb{K}}(\xi_m)$ and this completes the proof. □

REMARK 2.5.2. From Lemma 2.5.1, and Remarks 2.4.1 and 2.5.1, we easily deduce

$$\liminf_{\xi \to \xi_0; \xi \in \mathbb{K}} \mathcal{F}_{\mathbb{K}}(\xi) = \liminf_{\xi \to \xi_0; \xi \in \mathbb{K}} \mathcal{T}_{\mathbb{K}}(\xi) = \liminf_{\xi \to \xi_0; \xi \in \mathbb{K}} \mathcal{B}_{\mathbb{K}}(\xi) = \mathcal{C}_{\mathbb{K}}(\xi_0). \tag{2.5.5}$$

Concerning the equalities (2.5.5), as far as we know, the main and most difficult part, i.e. the equality of the second term to the last one has been proved independently by Ursescu [96] and by Cornet [36] in $\mathbb{R}^n$. See also Treiman [93] for the proof of the inclusion $\liminf_{\xi\to\xi_0;\xi\in\mathbb{K}} \mathcal{T}_{\mathbb{K}}(\xi) \subseteq \mathcal{C}_{\mathbb{K}}(\xi_0)$ in general Banach spaces. We emphasize that there are examples showing that the converse inclusion does not hold in infinite-dimensional Banach spaces. See, for instance, Treiman [93]. We notice that Ursescu [96] proves a characterization of $\mathcal{C}_{\mathbb{K}}(\xi)$ in general Banach spaces, pertaining also an immediate proof of Treiman's main result in [93].

PROPOSITION 2.5.1. *Let $\mathbb{K} \subseteq \mathbb{R}^n$ be locally closed and let $f:\mathbb{K}\to\mathbb{R}^n$ be continuous. Then, the following conditions are equivalent*:

(i) *for each $\xi\in\mathbb{K}$, $f(\xi)\in\mathcal{C}_{\mathbb{K}}(\xi)$,*
(ii) *for each $\xi\in\mathbb{K}$, $f(\xi)\in\mathcal{T}_{\mathbb{K}}(\xi)$,*
(iii) *for each $\xi\in\mathbb{K}$, $f(\xi)\in\mathcal{B}_{\mathbb{K}}(\xi)$.*

In general, if $\mathcal{G}:\mathbb{K}\rightsquigarrow\mathbb{R}^n$ is such that $\mathcal{C}_{\mathbb{K}}(\xi)\subseteq\mathcal{G}(\xi)\subseteq\mathcal{B}_{\mathbb{K}}(\xi)$ for each $\xi\in\mathbb{K}$, then each one of the conditions above is equivalent to:

(iv) *for each $\xi\in\mathbb{K}$, $f(\xi)\in\mathcal{G}(\xi)$.*

PROOF. In view of Remark 2.5.1, it suffices to show that (i) is equivalent to (iii). But this easily follows from Lemma 2.5.1 and this completes the proof. □

We notice that the equivalences in Proposition 2.5.1 were called to our attention by Ursescu [101].

3. Problems of viability

3.1. *Nagumo's viability theorem*

We begin with some background material we will need subsequently.

DEFINITION 3.1.1. Let $\mathbb{K}\subseteq\mathbb{R}^n$ be nonempty and $f:\mathbb{I}\times\mathbb{K}\to\mathbb{R}^n$. The subset $\mathbb{K}$ is *viable* with respect to f if for every $(\tau,\xi)\in\mathbb{I}\times\mathbb{K}$ there exists $T\in\mathbb{I}$, $T>\tau$, such that (1.1.1) has at least one solution, $u:[\tau,T]\to\mathbb{K}$, satisfying $u(\tau)=\xi$.

We can now proceed to the main result in this section.

THEOREM 3.1.1 (Nagumo [70]). *Let $\mathbb{K}\subset\mathbb{R}^n$ be a nonempty and locally closed set and let $f:\mathbb{I}\times\mathbb{K}\to\mathbb{R}^n$ be a continuous function. The necessary and sufficient condition in order that $\mathbb{K}$ be viable with respect to f is that, for every $(t,\xi)\in\mathbb{I}\times\mathbb{K}$, $f(t,\xi)\in\mathcal{T}_{\mathbb{K}}(\xi)$.*

3.2. *Proof of the necessity*

PROOF. In order to prove the necessity let $(t,\xi)\in\mathbb{I}\times\mathbb{K}$. Then, there exist $T\in\mathbb{I}$, $T>t$, and a function $u:[t,T]\to\mathbb{K}$, satisfying $u(t)=\xi$ and $u'(s)=f(s,u(s))$ for every $s\in[t,T]$. Consequently, we have

$$\lim_{h\downarrow 0}\frac{1}{h}\left\|\xi+hf(t,\xi)-u(t+h)\right\|=\lim_{h\downarrow 0}\left\|f\big(t,u(t)\big)-\frac{u(t+h)-u(t)}{h}\right\|=0.$$

But, this relation shows that, for every $(t,\xi)\in\mathbb{I}\times\mathbb{K}$, $f(t,\xi)\in\mathcal{T}_{\mathbb{K}}(\xi)$ and the proof of the necessity is complete.

We notice that, in fact, we have proved much more than claimed by the necessity part of Theorem 3.1.1. Namely, we deduced:

THEOREM 3.2.1. *If $\mathbb{K}$ is viable with respect to $f:\mathbb{I}\times\mathbb{K}\to\mathbb{R}^n$, then, for each $(t,\xi)\in\mathbb{I}\times\mathbb{K}$, we have*

$$\lim_{h\downarrow 0}\frac{1}{h}\operatorname{dist}\big(\xi+hf(t,\xi);\mathbb{K}\big)=0.$$

We notice that in Theorem 3.2.1 neither $\mathbb{K}$ is assumed to be locally closed, nor f to be continuous.

3.3. *Existence of approximate solutions*

PROOF OF THEOREM 3.1.1 (Continued). For the sake of simplicity, we divide the proof of the sufficiency into three steps. In the first one we shall prove the existence of a family of approximate solutions for the Cauchy problem (1.1.2) defined on intervals of the form $[\tau,c]$, with $c\in\mathbb{I}$. In the second step we will show that the problem (1.1.2) admits such approximate solutions, all defined on an interval $[\tau,T]$ independent of the "approximation order". Finally, in the last step, we shall prove the uniform convergence on $[\tau,T]$ of a sequence of such approximate solutions to a solution of the problem (1.1.2).

Let $(\tau,\xi)\in\mathbb{I}\times\mathbb{K}$ be arbitrary and let us choose $\rho>0$, $M>0$ and $T\in\mathbb{I}$, $T>\tau$, such that $B(\xi,\rho)\cap\mathbb{K}$ be closed,

$$\left\|f(t,x)\right\|\leqslant M \tag{3.3.1}$$

for every $t\in[\tau,T]$ and $x\in B(\xi,\rho)\cap\mathbb{K}$, and

$$(T-\tau)(M+1)\leqslant\rho. \tag{3.3.2}$$

The existence of these three numbers is ensured by the fact that $\mathbb{K}$ is locally closed (from where it follows the existence of $\rho>0$), by the continuity of f which implies its boundedness on $[\tau,T]\times B(\xi,\rho)$, and so the existence of $M>0$, and by the fact that $T\in\mathbb{I}$, $T>\tau$, can be chosen as close to τ as we wish. We will show that, once fixed an $\varepsilon \in (0,1)$ and the three numbers above, there exist three functions: $\sigma : [\tau, T] \to [\tau, T]$, nondecreasing, $g : [\tau, T] \to \mathbb{R}^n$, Riemann integrable and $u : [\tau, T] \to \mathbb{R}^n$, continuous, such that:

(i) $t - \varepsilon \leqslant \sigma(t) \leqslant t$ for every $t \in [\tau, T]$;
(ii) $\|g(t)\| \leqslant \varepsilon$ for every $t \in [\tau, T]$;
(iii) $u(\sigma(t)) \in B(\xi, \rho) \cap \mathbb{K}$ for every $t \in [\tau, T]$ and $u(T) \in B(\xi, \rho) \cap \mathbb{K}$;
(iv) u satisfies

$$u(t) = \xi + \int_\tau^t f\big(\sigma(s), u\big(\sigma(s)\big)\big)\,\mathrm{d}s + \int_\tau^t g(s)\,\mathrm{d}s$$

for every $t \in [\tau, T]$.

For the sake of simplicity, in all that follows, we will say that such a triple (σ, g, u) is an *ε-approximate solution* to the Cauchy problem (1.1.2) on the interval $[\tau, T]$. □

The first step. Let $\tau \in \mathbb{I}$, $\xi \in \mathbb{K}$ and let $\rho > 0$, $M > 0$ and $T \in \mathbb{I}$, $T > \tau$, be fixed as above. Let $\varepsilon \in (0,1)$. We begin by showing the existence of an ε-approximate solution on an interval $[\tau, c]$ with $c \in (\tau, T]$. Since for every $(t, \xi) \in \mathbb{I} \times \mathbb{K}$, $f(t, \xi) \in \mathcal{T}_{\mathbb{K}}(\xi)$, from Proposition 2.3.2, it follows that there exists $c \in (\tau, T]$, $c - \tau \leqslant \varepsilon$ and $p \in \mathbb{R}^n$ with $\|p\| \leqslant \varepsilon$ such that $\xi + (c - \tau) f(\tau, \xi) + (c - \tau) p \in \mathbb{K}$. At this point, we can define the functions $\sigma : [\tau, c] \to [\tau, c]$, $g : [\tau, c] \to \mathbb{R}^n$ and $u : [\tau, c] \to \mathbb{R}^n$ by

$$\begin{cases} \sigma(t) = \tau & \text{for } t \in [\tau, c], \\ g(t) = p & \text{for } t \in [\tau, c], \\ u(t) = \xi + (t - \tau) f(\tau, \xi) + (t - \tau) p & \text{for } t \in [\tau, c]. \end{cases}$$

One can readily see that the triple (σ, g, u) is an ε-approximate solution to the Cauchy problem (1.1.2) on the interval $[\tau, c]$. Indeed the conditions (i), (ii) and (iv) are obviously fulfilled, while (iii) follows from (3.3.1), (3.3.2) and (i). Indeed, let us observe that $u(\sigma(t)) = \xi$, and therefore we have $u(\sigma(t)) \in B(\xi, \rho) \cap \mathbb{K}$ for every $t \in [\tau, c]$. Obviously $u(c) \in \mathbb{K}$. Moreover, by (3.3.1) and (3.3.2), we have

$$\big\|u(c) - \xi\big\| \leqslant (c - \tau)\big\|f(\tau, \xi)\big\| + (c - \tau)\|p\| \leqslant (T - \tau)(M + 1) \leqslant \rho$$

for every $t \in [\tau, c]$. Thus (iii) is also satisfied.

The second step. Now, we will prove the existence of an ε-approximate solution defined on the whole interval $[\tau, T]$. To this aim we shall make use of Brezis–Browder Theorem 2.1.1, as follows. Let $\mathcal{S}$ be the set of all ε-approximate solutions to the problem (1.1.2) having the domains of definition of the form $[\tau, c]$ with $c \in (\tau, T]$. On $\mathcal{S}$ we define the relation "$\preceq$" by $(\sigma_1, g_1, u_1) \preceq (\sigma_2, g_2, u_2)$ if the domain of definition $[\tau, c_1]$ of the first triple is included in the domain of definition $[\tau, c_2]$ of the second triple, and the two ε-approximate solutions coincide on the common part of the domains. Obviously "$\preceq$" is a preorder relation on $\mathcal{S}$. Let us show first that each increasing sequence $((\sigma_m, g_m, u_m))_{m \in \mathbb{N}}$ is bounded from above. Indeed, let $((\sigma_m, g_m, u_m))_m$ be an increasing sequence, and let $c^* = \lim_m c_m$, where $[\tau, c_m]$ denotes the domain of definition of (σ_m, g_m, u_m). Clearly, $c^* \in (\tau, T]$. We will show that there exists at least one element, $(\sigma^*, g^*, u^*) \in \mathcal{S}$, defined on $[\tau, c^*]$ and satisfying $(\sigma_m, g_m, u_m) \preceq (\sigma^*, g^*, u^*)$ for each $m \in \mathbb{N}$. In order to do this, we have to prove first that there exists $\lim_m u_m(c_m)$. For each $m, k \in \mathbb{N}$, $m \leqslant k$, we have $u_m(s) = u_k(s)$ for all $s \in [\tau, c_m]$. Taking into account (iii), (iv) and (3.3.1), we deduce

$$\begin{aligned}\left\|u_m(c_m) - u_k(c_k)\right\| &\leqslant \int_{c_m}^{c_k} \left\|f\big(\sigma_k(s), u_k\big(\sigma_k(s)\big)\big)\right\| \mathrm{d}s + \int_{c_m}^{c_k} \left\|g_k(s)\right\| \mathrm{d}s \\ &\leqslant (M + \varepsilon)|c_k - c_m|\end{aligned}$$

for every $m, k \in \mathbb{N}$, which proves that there exists $\lim_{m\to\infty} u_m(c_m)$. Since for every $m \in \mathbb{N}$, $u_m(c_m) \in B(\xi, \rho) \cap \mathbb{K}$, and the latter is closed, it readily follows that $\lim_{m\to\infty} u_m(c_m) \in B(\xi, \rho) \cap \mathbb{K}$. Furthermore, because all the functions in the set $\{\sigma_m;\ m \in \mathbb{N}\}$ are nondecreasing, with values in $[\tau, c^*]$, and satisfy $\sigma_m(c_m) \leqslant \sigma_p(c_p)$ for every $m, p \in \mathbb{N}$ with $m \leqslant p$, there exists $\lim_{m\to\infty} \sigma_m(c_m)$ and this limit belongs to $[\tau, c^*]$. This shows that we can define the triple of functions $(\sigma^*, g^*, u^*) : [\tau, c^*] \to [\tau, c^*] \times \mathbb{R}^n \times \mathbb{R}^n$ by

$$\sigma^*(t) = \begin{cases} \sigma_m(t) & \text{for } t \in [\tau, c_m],\ m \in \mathbb{N}, \\ \lim\limits_{m\to\infty} \sigma_m(c_m) & \text{for } t = c^*, \end{cases}$$

$$g^*(t) = \begin{cases} g_m(t) & \text{for } t \in [\tau, c_m],\ m \in \mathbb{N}, \\ 0 & \text{for } t = c^*, \end{cases}$$

$$u^*(t) = \begin{cases} u_m(t) & \text{for } t \in [\tau, c_m],\ m \in \mathbb{N}, \\ \lim\limits_{m\to\infty} u_m(c_m) & \text{for } t = c^*. \end{cases}$$

One can easily see that (σ^*, g^*, u^*) is an ε-approximate solution which is a majorant for $((\sigma_m, g_m, u_m))_m$. Let us define the function $\mathcal{M} : \mathcal{S} \to \mathbb{R} \cup \{+\infty\}$ by $\mathcal{M}((\sigma, g, u)) = c$, where $[\tau, c]$ is the domain of definition of (σ, g, u). Clearly $\mathcal{M}$ satisfies the hypotheses of Brezis–Browder Theorem 2.1.1. Then, $\mathcal{S}$ contains at least one $\mathcal{M}$-maximal element $(\bar\sigma, \bar g, \bar u)$, defined on $[\tau, \bar c]$. In other words, if $(\tilde\sigma, \tilde g, \tilde u) \in \mathcal{S}$, defined on $[\tau, \tilde c]$, satisfies $(\bar\sigma, \bar g, \bar u) \preceq (\tilde\sigma, \tilde g, \tilde u)$, then we necessarily have $\bar c = \tilde c$. We will show next that $\bar c = T$. Indeed, let us assume by contradiction that $\bar c < T$. Then, taking into account the fact that $\bar u(\bar c) \in B(\xi, \rho) \cap \mathbb{K}$, we deduce that

$$\begin{aligned}\left\|\bar u(\bar c) - \xi\right\| &\leqslant \int_\tau^{\bar c} \left\|f\big(\bar\sigma(s), \bar u\big(\bar\sigma(s)\big)\big)\right\| \mathrm{d}s + \int_\tau^{\bar c} \left\|\bar g(s)\right\| \mathrm{d}s \leqslant (\bar c - \tau)(M + \varepsilon) \\ &\leqslant (\bar c - \tau)(M + 1) < (T - \tau)(M + 1) \leqslant \rho.\end{aligned}$$

Then, as $\bar u(\bar c) \in \mathbb{K}$ and $f(\bar c, \bar u(\bar c)) \in \mathcal{T}_{\mathbb{K}}(\bar u(\bar c))$, there exist $\delta \in (0, T - \bar c)$, $\delta \leqslant \varepsilon$ and $p \in \mathbb{R}^n$ such that $\|p\| \leqslant \varepsilon$ and $\bar u(\bar c) + \delta f(\bar c, \bar u(\bar c)) + \delta p \in \mathbb{K}$. From the inequality above, it follows that we can diminish δ if necessary, in order to have $\|\bar{u}(\bar{c})+\delta[f(\bar{c},\bar{u}(\bar{c}))+p]-\xi\|\leqslant\rho$. Let us define the functions $\sigma:[\tau,\bar{c}+\delta]\to[\tau,\bar{c}+\delta]$ and $g:[\tau,\bar{c}+\delta]\to\mathbb{R}^n$ by

$$\sigma(t)=\begin{cases}\bar{\sigma}(t) & \text{for } t\in[\tau,\bar{c}],\\ \bar{c} & \text{for } t\in(\bar{c},\bar{c}+\delta],\end{cases}$$

$$g(t)=\begin{cases}\bar{g}(t) & \text{for } t\in[\tau,\bar{c}],\\ p & \text{for } t\in(\bar{c},\bar{c}+\delta].\end{cases}$$

Clearly, g is Riemann integrable on $[\tau,\bar{c}+\delta]$ and $\|g(t)\|\leqslant\varepsilon$ for every $t\in[\tau,\bar{c}+\delta]$. In addition, for every $t\in[\tau,\bar{c}+\delta]$, $\sigma(t)\in[\tau,\bar{c}]$, and therefore $\bar{u}(\sigma(t))$ is well-defined and belongs to the set $B(\xi,\rho)\cap\mathbb{K}$. Accordingly, we can define $u:[\tau,\bar{c}+\delta]\to\mathbb{R}^n$ by

$$u(t)=\xi+\int_\tau^t f\big(\sigma(s),\bar{u}\big(\sigma(s)\big)\big)\,\mathrm{d}s+\int_\tau^t g(s)\,\mathrm{d}s$$

for every $t\in[\tau,\bar{c}+\delta]$. Clearly u coincides with $\bar{u}$ on $[\tau,\bar{c}]$ and then it readily follows that u, σ and g satisfy all the conditions in (i) and (ii). In order to prove (iii) and (iv), let us observe that

$$u(t)=\begin{cases}\bar{u}(t) & \text{for } t\in[\tau,\bar{c}],\\ u(\bar{c})+(t-\bar{c})f\big(\bar{c},\bar{u}(\bar{c})\big)+(t-\bar{c})p & \text{for } t\in(\bar{c},\bar{c}+\delta].\end{cases}$$

Then u satisfies the equation in (iv). Since

$$u\big(\sigma(t)\big)=\begin{cases}\bar{u}\big(\bar{\sigma}(t)\big) & \text{for } t\in[\tau,\bar{c}],\\ \bar{u}(\bar{c}) & \text{for } t\in[\bar{c},\bar{c}+\delta],\end{cases}$$

it follows that $u(\sigma(t))\in B(\xi,\rho)\cap\mathbb{K}$. Furthermore, from the choice of δ and p, we have both $u(\bar{c}+\delta)=\bar{u}(\bar{c})+\delta f(\bar{c},\bar{u}(\bar{c}))+\delta p\in\mathbb{K}$, and

$$\big\|u(\bar{c}+\delta)-\xi\big\|=\big\|\bar{u}(\bar{c})+\delta f\big(\bar{c},\bar{u}(\bar{c})\big)+\delta p-\xi\big\|\leqslant\rho$$

and consequently u satisfies (iii). Thus $(\sigma,g,u)\in\mathcal{S}$. Furthermore, since $(\bar{\sigma},\bar{g},\bar{u})\preceq(\sigma,g,u)$ and $\bar{c}<\bar{c}+\delta$, it follows that $(\bar{\sigma},\bar{g},\bar{u})$ is not an $\mathcal{M}$-maximal element. But this is absurd. This contradiction can be eliminated only if each maximal element in the set $\mathcal{S}$ is defined on $[\tau,T]$.

3.4. *Convergence of approximate solutions*

The third step. Let $(\varepsilon_k)_{k\in\mathbb{N}}$ be a sequence from $(0,1)$ decreasing to 0 and let $((\sigma_k,g_k,u_k))_{k\in\mathbb{N}}$ be a sequence of ε_k-approximate solutions defined on $[\tau,T]$. From (i) and (ii), it follows that

$$\lim_{k\to\infty}\sigma_k(t)=t\quad\text{and}\quad\lim_{k\to\infty}g_k(t)=0\tag{3.4.1}$$

uniformly on $[\tau, T]$. On the other hand, from (iii), (iv) and (3.3.2), we have

$$\begin{aligned}\|u_k(t)\| &\leqslant \|u_k(t)-\xi\| + \|\xi\| \\ &\leqslant \int_\tau^T \|f(\sigma_k(s), u_k(\sigma_k(s)))\|\,\mathrm{d}s + \int_\tau^T \|g_k(s)\|\,\mathrm{d}s + \|\xi\| \\ &\leqslant (T-\tau)(M+1) + \|\xi\| \leqslant \rho + \|\xi\|\end{aligned}$$

for every $k \in \mathbb{N}$ and every $t \in [\tau, T]$. Hence, the sequence $(u_k)_{k\in\mathbb{N}}$ is uniformly bounded on $[\tau, T]$. Again from (iv), we have

$$\begin{aligned}\|u_k(t)-u_k(s)\| &\leqslant \left|\int_s^t \|f(\sigma_k(\tau), u_k(\sigma_k(\tau)))\|\,\mathrm{d}\tau\right| + \left|\int_s^t \|g_k(\tau)\|\,\mathrm{d}\tau\right| \\ &\leqslant (M+1)|t-s|\end{aligned}$$

for every $t, s \in [\tau, T]$. Consequently the sequence $(u_k)_{k\in\mathbb{N}}$ is equicontinuous on $[\tau, T]$. From Arzelà–Ascoli theorem—see Vrabie [106, Theorem 8.2.1, p. 320]—it follows that, at least on a subsequence, $(u_k)_{k\in\mathbb{N}}$ is uniformly convergent on $[\tau, T]$ to a function $u : [\tau, T] \to \mathbb{R}^n$. Taking into account of (iii), (3.4.1) and of the fact that $B(\xi, \rho) \cap \mathbb{K}$ is closed, we deduce that $u(t) \in B(\xi, \rho) \cap \mathbb{K}$ for every $t \in [\tau, T]$. Passing to the limit in the equation

$$u_k(t) = \xi + \int_\tau^t f(\sigma_k(\tau), u_k(\sigma_k(s)))\,\mathrm{d}s + \int_\tau^t g_k(s)\,\mathrm{d}s$$

and taking into account (3.4.1), we deduce that

$$u(t) = \xi + \int_\tau^t f(s, u(s))\,\mathrm{d}s$$

for every $t \in [\tau, T]$, which achieves the proof of the theorem. □

From Remark 2.3.1 combined with Theorem 3.1.1, we deduce Peano's local existence theorem 1.1.1. We mention that Theorem 1.1.2 too is a direct consequence of Theorem 3.1.1 combined with the observation below.

REMARK 3.4.1. Let $\mathbb{D}$ be a nonempty and open subset in $\mathbb{R}^n$ and let $U : \mathbb{D} \to \mathbb{R}$ be a function of class C^1 with $\nabla U(\xi) \neq 0$ on $\mathbb{D}$. Let $c \in \mathbb{R}$ be such that $\mathbb{K} = \{\xi \in \Omega;\ U(\xi) = c\}$ is nonempty. Then $\eta \in \mathbb{R}^n$ is tangent to $\mathbb{K}$ at the point $\xi \in \mathbb{K}$ if and only if $\langle \eta, \nabla U(\xi)\rangle = 0$. In other words, in this case, $\mathcal{T}_{\mathbb{K}}(\xi)$ coincides with the set of vectors in the tangent plane to $\mathbb{K}$ at ξ. Indeed, let us observe that a vector $\eta \in \mathcal{T}_{\mathbb{K}}(\xi)$ if and only if there exists a function $u : [0, 1] \to \mathbb{K}$ with $u(0) = \xi$, differentiable at $t = 0$, with $u'(0) = \eta$, and such that

$$\lim_{t\downarrow 0} \frac{1}{t} \|\xi + t\eta - u(t)\| = 0.$$

But, in the particular case of the set $\mathbb{K}$ considered, this relation holds if and only if $\langle \eta, \nabla U(\xi)\rangle = 0$, which achieves the proof.

Summing up, and using Proposition 2.5.1, we deduce:

THEOREM 3.4.1. *Let* $\mathbb{K}$ *be a nonempty and locally closed subset in* $\mathbb{R}^n$ *and let* $f : \mathbb{I} \times \mathbb{K} \to \mathbb{R}^n$ *be continuous. Then the following conditions are equivalent*:

(i) *for every* $(t, \xi) \in \mathbb{I} \times \mathbb{K}$, $f(t, \xi) \in \mathcal{C}_{\mathbb{K}}(\xi)$,
(ii) *for every* $(t, \xi) \in \mathbb{I} \times \mathbb{K}$, $f(t, \xi) \in \mathcal{T}_{\mathbb{K}}(\xi)$,
(iii) *for every* $(t, \xi) \in \mathbb{I} \times \mathbb{K}$, $f(t, \xi) \in \mathcal{B}_{\mathbb{K}}(\xi)$,
(iv) *the set* $\mathbb{K}$ *is viable with respect to* f.

In general, if $\mathcal{G} : \mathbb{K} \rightsquigarrow \mathbb{R}^n$ *is such that* $\mathcal{C}_{\mathbb{K}}(\xi) \subseteq \mathcal{G}(\xi) \subseteq \mathcal{B}_{\mathbb{K}}(\xi)$ *for each* $\xi \in \mathbb{K}$, *then each one of the conditions above is equivalent to*

(v) *for each* $\xi \in \mathbb{K}$, $f(t, \xi) \in \mathcal{G}(\xi)$.

3.5. *Existence of noncontinuable solutions*

In this section we will prove some results concerning the existence of noncontinuable, or even global solutions to (1.1.1). We recall that a solution $u : [\tau, T) \to \mathbb{K}$ to (1.1.1) is called *noncontinuable*, if there is no other solution $v : [\tau, \widetilde{T}) \to \mathbb{K}$ of the same equation, with $T < \widetilde{T}$ and satisfying $u(t) = v(t)$ for all $t \in [\tau, T)$. The solution u is called *global* if $T = \sup \mathbb{I}$. The next theorem follows from Brezis–Browder Theorem 2.1.1.

THEOREM 3.5.1. *Let* $\mathbb{K} \subseteq \mathbb{R}^n$ *be nonempty and let* $f : \mathbb{I} \times \mathbb{K} \to \mathbb{R}^n$ *be a possibly discontinuous function. Then, the following conditions are equivalent*:

(i) $\mathbb{K}$ *is viable with respect to* f,
(ii) *for each* $(\tau, \xi) \in \mathbb{I} \times \mathbb{K}$ *there exists at least one noncontinuable solution* $u : [\tau, T) \to \mathbb{K}$ *of* (1.1.1), *satisfying* $u(\tau) = \xi$.

PROOF. Clearly (ii) implies (i). To prove that (i) implies (ii) it suffices to show that every solution u can be continued up to a noncontinuable one. To this aim, we will make use of Brezis–Browder Theorem 2.1.1. Let $\mathcal{S}$ be the set of all solutions to (1.1.1). On $\mathcal{S}$ which, by virtue of (i), is nonempty, we define the binary relation "$\preceq$" by $u \preceq v$ if the domain $[\tau, T_v)$ of v is larger that the domain $[\tau, T_u)$ of u, i.e. $T_u \leqslant T_v$, and $u(t) = v(t)$ for all $t \in [\tau, T_u)$. Clearly "$\preceq$" is a preorder on $\mathcal{S}$. Next, let $(u_m)_m$ be an increasing sequence in $\mathcal{S}$, and let us denote by $[\tau, T_m)$ the domain of definition of u_m. Let $T^* = \lim_{m\to\infty} T_m$, which can be finite, or not, and let us define $u^* : [\tau, T^*) \to \mathbb{K}$ by $u^*(t) = u_m(t)$ for each $t \in [\tau, T_m)$. Since $(T_m)_m$ is increasing and $u_m(t) = u_k(t)$ for each $m \leqslant k$ and each $t \in [\tau, T_m)$, u^* is well-defined and belongs to $\mathcal{S}$. Moreover, u^* is a majorant of $(u_m)_m$. Thus each increasing sequence in $\mathcal{S}$ is bounded from above. Moreover, the function $\mathcal{M} : \mathcal{S} \to \mathbb{R} \cup \{+\infty\}$, defined by $\mathcal{M}(v) = T_v$, for each $v \in \mathcal{S}$, is monotone, and therefore we are in the hypotheses of Theorem 2.1.1. Accordingly, for $u \in \mathcal{S}$, there exists at least one element $\bar{u} \in \mathcal{S}$ with $u \preceq \bar{u}$ and, in addition, $\bar{u} \preceq \tilde{u}$ implies $T_{\tilde{u}} = T_{\bar{u}}$. But this means that $\bar{u}$ is noncontinuable, and, of course, that it extends u. The proof is complete. □

THEOREM 3.5.2. *Let $\mathbb{K}$ be a nonempty and locally closed subset in $\mathbb{R}^n$, and let $f: \mathbb{I} \times \mathbb{K} \to \mathbb{R}^n$ be a continuous function. Then a necessary and sufficient condition in order that for each $(\tau, \xi) \in \mathbb{I} \times \mathbb{K}$ there exists at least one noncontinuable solution to* (1.1.1) *satisfying $u(\tau) = \xi$ is one of the five equivalent conditions in Theorem* 3.4.1.

PROOF. In view of Theorem 3.4.1, each one of the first five conditions is equivalent to the viability of $\mathbb{K}$ with respect to f. The conclusion follows from Theorem 3.5.1, and the proof is complete. □

In order to obtain global existence, some extra growth conditions on f are needed. We discuss below a very natural one, introduced in a more general framework in Vrabie [102, Definition 3.2.1, p. 95].

DEFINITION 3.5.1. A function $f: \mathbb{I} \times \mathbb{K} \to \mathbb{R}^n$ is called *positively sublinear* if there exists a norm $\|\cdot\|$ on $\mathbb{R}^n$ such that, for each $T \in \mathbb{I}$, there exist $a > 0$, $b \in \mathbb{R}$ and $c > 0$ satisfying

$$\big\|f(t,\xi)\big\| \leqslant a\|\xi\| + b$$

for each $(t, \xi) \in \mathbb{K}_+^c(f)$, where

$$\mathbb{K}_+^c(f) = \big\{(t,\xi) \in \mathbb{I} \times \mathbb{K};\ t \leqslant T,\ \|\xi\| > c \text{ and } \big[\xi, f(t,\xi)\big]_+ > 0\big\}.$$

As concerns the existence of global solutions we have:

THEOREM 3.5.3. *Let $\mathbb{K}$ be a nonempty and closed subset in $\mathbb{R}^n$, and let $f: \mathbb{I} \times \mathbb{K} \to \mathbb{R}^n$ be a continuous and positively sublinear function. Then a necessary and sufficient condition in order that for each $(t, \xi) \in \mathbb{I} \times \mathbb{K}$ there exists at least one global solution to* (1.1.1) *satisfying $u(\tau) = \xi$ is each one of the five equivalent conditions in Theorem* 3.4.1.

PROOF. Clearly, each one of the five conditions is necessary. To complete the proof it suffices to show that, whenever $\mathbb{K}$ is viable with respect to f, then, for each $(\tau, \xi) \in \mathbb{I} \times \mathbb{K}$, there exists at least one global solution $u: [\tau, T) \to \mathbb{K}$ to (1.1.1) satisfying $u(\tau) = \xi$. To this aim, let $(\tau, \xi) \in \mathbb{I} \times \mathbb{K}$ and let $u: [\tau, T) \to \mathbb{K}$ be a noncontinuable solution to (1.1.1) satisfying $u(\tau) = \xi$. We will show that $T = \sup \mathbb{I}$. To this aim, let us assume the contrary, i.e., that $T < \sup \mathbb{I}$. In particular, this means that $T < +\infty$. Since $u'(s) = f(s, (u(s))$ for all $s \in [\tau, T)$, we deduce

$$\big[u(s), u'(s)\big]_+ = \big[u(s), f\big(s, u(s)\big)\big]_+.$$

Since $[u(s), u'(s)]_+ = \frac{\mathrm{d}^+}{\mathrm{d}s}(\|u(s)\|)$ for $s \in [\tau, T)$, where $\|\cdot\|$ is the norm whose existence is ensured by Definition 3.5.1, integrating from τ to t the last equality, we get successively

$$\big\|u(t)\big\| = \|\xi\| + \int_\tau^t \big[u(s), f\big(s, u(s)\big)\big]_+ \mathrm{d}s$$

$$
\begin{aligned}
&= \|\xi\| + \int_{\{\tau \leqslant s \leqslant t;\, \|u(s)\| \leqslant c\}} \big[u(s), f\big(s, u(s)\big)\big]_+ \, \mathrm{d}s \\
&\quad + \int_{\{\tau \leqslant s \leqslant t;\, \|u(s)\| > c\}} \big[u(s), f\big(s, u(s)\big)\big]_+ \, \mathrm{d}s \\
&\leqslant \|\xi\| + c\lambda\big(\big\{s \in [\tau, t];\ \big\|u(s)\big\| \leqslant c\big\}\big) \\
&\quad + \int_{\{\tau \leqslant s \leqslant t;\, \|u(s)\| > c\}} \big[a\big\|u(s)\big\| + b\big] \, \mathrm{d}s \\
&\leqslant \|\xi\| + (b + c)(T - \tau) + a \int_\tau^t \big\|u(s)\big\| \, \mathrm{d}s.
\end{aligned}
$$

Here, as usual, λ denotes the Lebesgue measure on $\mathbb{R}$. Thanks to Gronwall's inequality—see Vrabie [106, Lemma 1.5.2, p. 46]—u is bounded on $[\tau, T)$ and, since $T < +\infty$, it follows that $\{f(t, u(t));\ t \in [\tau, T)\}$ is bounded. Therefore u is globally Lipschitz on $[\tau, T)$ and accordingly there exists $\lim_{t \uparrow T} u(t) = u^*$. Since $\mathbb{K}$ is closed and $T < \sup \mathbb{I}$, it follows that $(T, u^*) \in \mathbb{I} \times \mathbb{K}$. Using this observation and recalling that $\mathbb{K}$ is viable with respect to f, we conclude that u can be continued to the right of T. But this is absurd, because u is noncontinuable. This contradiction can be eliminated only if $T = \sup \mathbb{I}$, and this achieves the proof. □

As, whenever $\mathbb{K}$ is compact, each continuous function $f : \mathbb{I} \times \mathbb{K} \to \mathbb{R}^n$ is positively sublinear, from Theorem 3.5.3 it readily follows:

COROLLARY 3.5.1. *Let $\mathbb{K}$ be a nonempty and compact subset of $\mathbb{R}^n$, and let $f : \mathbb{I} \times \mathbb{K} \to \mathbb{R}^n$ be continuous. Then a necessary and sufficient condition in order that for each $(\tau, \xi) \in \mathbb{I} \times \mathbb{K}$ there exists at least one solution, $u : [\tau, T) \to \mathbb{K}$ to* (1.1.1), *satisfying $T = \sup \mathbb{I}$ and $u(\tau) = \xi$, is any one of the five equivalent conditions in Theorem* 3.4.1.

3.6. *Viability of the relative closure*

PROPOSITION 3.6.1 (Roxin [86]). *Let $\mathbb{D} \subseteq \mathbb{R}^n$ be open, let $\mathbb{K} \subseteq \mathbb{D}$ and let $f : \mathbb{I} \times \mathbb{D} \to \mathbb{R}^n$ be continuous. If $\mathbb{K}$ is viable with respect to f, then its closure relative to $\mathbb{D}$, $\overline{\mathbb{K}}^{\mathbb{D}}$, is also viable with respect to f.*

PROOF. Let $\tau \in \mathbb{I}$ and let $(\xi_k)_k$ be a sequence in $\mathbb{K}$ convergent to $\xi \in \overline{\mathbb{K}}^{\mathbb{D}}$. Since $\mathbb{K}$ is viable with respect to f, there exists a sequence $(u(\cdot, \xi_k))_k$ of $\mathbb{K}$-valued noncontinuable solutions to (1.1.1) satisfying $u(\tau, \xi_k) = \xi_k$, for $k = 1, 2, \ldots$. It is well known that the intersection of the domains of this sequence contains a nontrivial interval $[\tau, T]$. See, for instance, Vrabie [106, Lemma 3.2.1, p. 107]. Moreover, diminishing T if necessary, we may assume that there exists $\rho > 0$ such that $u(t, \xi_k) \in B(\xi, \rho) \subseteq \mathbb{D}$, for all $k \in \mathbb{N}$, and $t \in [\tau, T]$. By a compactness argument involving Arzelà–Ascoli theorem, we conclude that, on a subsequence at least, we have $\lim_{k \to \infty} u(\cdot, \xi_k) = u(\cdot, \xi)$ uniformly on $[\tau, T]$. Thus $u(t, \xi) \in \overline{\mathbb{K}}^{\mathbb{D}}$ for all $t \in [\tau, T]$, and this completes the proof. □

3.7. *Comparison and viability*

The next theorem, called to our attention by Ursescu [101], gives a characterization of the viability of an epigraph of a certain function in the terms of a differential inequality. Similar results can be found in Clarke et al. [33, p. 266]. Throughout, we denote by $[D_+x](t)$ the *right lower Dini derivative* of the function x at t, i.e.

$$[D_+x](t) = \liminf_{h\downarrow 0} \frac{x(t+h)-x(t)}{h}.$$

THEOREM 3.7.1. *Let* $\omega : \mathbb{I}\times\mathbb{R}_+ \to \mathbb{R}$ *and* $v : [\tau, T) \to \mathbb{R}_+$ *be continuous, with* $[\tau, T) \subseteq \mathbb{I}$. *Then*

$$\operatorname{epi}(v) = \bigl\{(t,\eta);\ v(t) \leqslant \eta,\ t \in [\tau, T)\bigr\}$$

is viable with respect to $(t, y) \mapsto (1, \omega(t, y))$ *if and only if* v *satisfies*

$$[D_+v](t) \leqslant \omega\bigl(t, v(t)\bigr) \tag{3.7.1}$$

for each $t \in [\tau, T)$.

PROOF. *Sufficiency*. It suffices to show that the set $\{(t, v(t));\ t \in [\tau, T)\}$, included in the boundary $\partial\operatorname{epi}(v)$ of $\operatorname{epi}(v)$, satisfies the Nagumo's tangency condition (1.1.3). From (3.7.1) it follows that

$$\left[D_+\left(v(\cdot) - \int_\tau^{\cdot} \omega\bigl(s, v(s)\bigr)\,\mathrm{d}s\right)\right](t) \leqslant 0$$

for each $t \in [\tau, T)$. Thus, in view of a classical result in Hobson [56, p. 365], we necessarily have that $t \mapsto v(t) - \int_\tau^t \omega(s, v(s))\,\mathrm{d}s$ is non-increasing on $[\tau, T]$. So, for each $t \in [\tau, T)$ and $h > 0$ such that $t + h < T$, we have

$$\left(t+h, v(t) + \int_t^{t+h} \omega\bigl(s, v(s)\bigr)\,\mathrm{d}s\right) \in \operatorname{epi}(v),$$

and therefore

$$\begin{aligned}
&\operatorname{dist}\bigl(\bigl(t, v(t)\bigr) + h\bigl(1, \omega\bigl(t, v(t)\bigr)\bigr); \operatorname{epi}(v)\bigr)\\
&\quad\leqslant \left\|\bigl(t, v(t)\bigr) + h\bigl(1, \omega\bigl(t, v(t)\bigr)\bigr) - \left(t+h, v(t) + \int_t^{t+h} \omega\bigl(s, v(s)\bigr)\,\mathrm{d}s\right)\right\|\\
&\quad= \left|h\omega\bigl(t, v(t)\bigr) - \int_t^{t+h} \omega\bigl(s, v(s)\bigr)\,\mathrm{d}s\right|.
\end{aligned}$$

Dividing by $h > 0$ and passing to $\liminf$ for $h \downarrow 0$ we get (1.1.3) and this completes the proof of the sufficiency.

Necessity. Let us assume that $\operatorname{epi}(v)$ is viable with respect to the function $(t, y) \mapsto (1, \omega(t, y))$, let $t \in [\tau, T)$, and let (s, x) be a solution to $s' = 1$, $x'(s) = \omega(s, x(s))$, satisfying the initial conditions $s(0) = t$ and $x(0) = v(t)$, and which remains in $\operatorname{epi}(v)$. We have

$$\frac{v(t+h) - v(t)}{h} \leqslant \frac{x(h) - x(0)}{h}.$$

Accordingly

$$[D_+ v](t) \leqslant \omega\big(s(0), x(0)\big) = \omega\big(t, v(t)\big),$$

and this achieves the proof of the necessity. □

DEFINITION 3.7.1. A function $\omega : \mathbb{I} \times [0, a) \to \mathbb{R}$, $0 < a \leqslant +\infty$, is a *comparison* function if $\omega(t, 0) = 0$ for each $t \in [0, a)$, and for each $[\tau, T) \subseteq \mathbb{I}$, the only continuous function $x : [\tau, T) \to [0, a)$, satisfying

$$\begin{cases} [D_+ x](t) \leqslant \omega\big(t, x(t)\big) & \text{for all } t \in [\tau, T), \\ x(\tau) = 0, \end{cases}$$

is the null function.

COROLLARY 3.7.1. *Let $\omega : \mathbb{I} \times \mathbb{R}_+ \to \mathbb{R}$ be continuous and such that, for each $\tau \in \mathbb{I}$, the Cauchy problem $y'(t) = \omega(t, y(t))$, $y(\tau) = 0$ has only the null solution. Then ω is a comparison function.*

PROOF. Let $v : [\tau, T] \to \mathbb{R}_+$ be any solution to (3.7.1). By Theorem 3.7.1, $\operatorname{epi}(v)$ is viable with respect to $(t, y) \mapsto (1, \omega(t, y))$. So, the unique solution $y : [\tau, T) \to \mathbb{R}_+$ of the Cauchy problem $y'(t) = \omega(t, y(t))$, $y(\tau) = 0$ satisfies $0 \leqslant v(t) \leqslant y(t) = 0$. □

3.8. *Viable preordered subsets*

Let us assume now that $\mathbb{K}$ is a nonempty subset in $\mathbb{R}^n$, and let "$\preceq$" be a *preorder* on $\mathbb{K}$, i.e. a reflexive and transitive binary relation. For our later purposes, it is convenient to identify "$\preceq$" with the multifunction $\mathcal{P} : \mathbb{K} \rightsquigarrow \mathbb{K}$, defined by

$$\mathcal{P}(\xi) = \{\eta \in \mathbb{K};\ \xi \preceq \eta\}$$

for each $\xi \in \mathbb{K}$, and called also a preorder. We say that a preorder "$\preceq$", or $\mathcal{P}$ is *closed* if "$\preceq$" is a closed subset in $\mathbb{R}^n \times \mathbb{R}^n$. Let $f : \mathbb{I} \times \mathbb{K} \to \mathbb{R}^n$, and let us consider the differential equation (1.1.1). We say that "$\preceq$", or $\mathcal{P}$, is *viable with respect to* f if for each $(\tau, \xi) \in \mathbb{I} \times \mathbb{K}$, there exist $[\tau, T] \subseteq \mathbb{I}$ and a solution $u : [\tau, T] \to \mathbb{R}^n$ of (1.1.1) satisfying $u(\tau) = \xi$, $u(t) \in \mathbb{K}$ for each $t \in [\tau, T]$ and u is "$\preceq$"-monotone on $[\tau, T]$, i.e., for each $\tau \leqslant s \leqslant t \leqslant T$, we have $u(s) \preceq u(t)$. The next lemma in Cârjă and Ursescu [25] is the main tool in our forthcoming analysis.

LEMMA 3.8.1. *Let $f : \mathbb{I} \times \mathbb{K} \to \mathbb{R}^n$ be continuous and let $\mathcal{P}$ be a preorder on $\mathbb{K}$. If $\mathcal{P}$ is viable with respect to f then, for each $\xi \in \mathbb{K}$, $\mathcal{P}(\xi)$ is viable with respect to f. If $\mathcal{P}$ is closed in $\mathbb{R}^n \times \mathbb{R}^n$ and, for each $\xi \in \mathbb{K}$, $\mathcal{P}(\xi)$ is viable with respect to f, then $\mathcal{P}$ is viable with respect to f.*

PROOF. Clearly, if $\mathcal{P}$ is viable with respect to f, then, for all $\xi \in \mathbb{K}$, $\mathcal{P}(\xi)$ is viable with respect to f.

Now, if $\mathcal{P}$ is closed, then, for each $\xi \in \mathbb{K}$, $\mathcal{P}(\xi)$ is a fortiori closed. Let us assume that, for each $\xi \in \mathbb{K}$, $\mathcal{P}(\xi)$ is viable with respect to f. Let $(\tau, \xi) \in \mathbb{I} \times \mathbb{K}$. We shall show that there exist $[\tau, T] \subseteq \mathbb{I}$ and at least one solution $u : [\tau, T] \to \mathbb{K}$ of (1.1.1), with $u(\tau) = \xi$, and such that $u([s, T]) \subseteq \mathcal{P}(u(s))$ for each $s \in [\tau, T]$. To this aim, we proceed in several steps.

In the first step, we note that, by standard qualitative arguments—see, for instance, Vrabie [106, Lemma 3.2.1, p. 107]—one can show that there exists $T > \tau$, $T \in \mathbb{I}$, such that for every noncontinuable solution $u : [\tau, T_m) \to \mathbb{K}$ to (1.1.1) with $u(\tau) = \xi$ we have $T < T_m$. Since $\mathcal{P}(\xi)$ is viable with respect to f, there exists a solution $u : [\tau, T] \to \mathbb{K}$ of (1.1.1) with $u(\tau) = \xi$ and $u([\tau, T]) \subseteq \mathcal{P}(\xi)$.

In the second step, we remark that, for every solution $v : [\tau, T] \to \mathbb{K}$ to (1.1.1), with $v(\tau) = \xi$ and $v([\tau, T]) \subseteq \mathcal{P}(\xi)$, and for every $\nu \in [\tau, T)$, there exists a solution $w : [\tau, T] \to \mathbb{K}$ to (1.1.1) such that w equals v on $[\tau, \nu]$ and $w([\nu, T]) \subseteq \mathcal{P}(w(\nu))$.

In the third step, we observe that, thanks to the first two steps, for every nonempty and finite subset S of $[\tau, T)$, with $\tau \in S$, there exists a solution $u : [\tau, T] \to \mathbb{K}$ of (1.1.1) satisfying both $u(\tau) = \xi$ and $u([s, T]) \subseteq \mathcal{P}(u(s))$ for all $s \in S$.

In the fourth step, we consider a sequence $(S_k)_{k \in \mathbb{N}}$ of nonempty finite subsets of $[\tau, T)$ such that $\tau \in S_k$, $S_k \subseteq S_{k+1}$ for each $n \in \mathbb{N}$, and the set $S = \cup_{k \in \mathbb{N}} S_k$ is dense in $[\tau, T]$. For example, we can take

$$S_k = \left\{ \tau + \frac{i}{2^k}(T - \tau);\ i \in \left\{0, 1, \ldots, 2^k - 1\right\} \right\}.$$

Further, we shall make use of the third step to get a sequence of solutions $(u_k : [\tau, T] \to \mathbb{K})_k$ to (1.1.1), satisfying $u_k(\tau) = \xi$ and such that $u_k([s, T]) \subseteq \mathcal{P}(u_k(s))$ for each $k \in \mathbb{N}$ and each $s \in S_k$. Now, by virtue of Arzelà–Ascoli theorem, we can assume, taking a subsequence if necessary, that the sequence $(u_k)_k$ converges uniformly on $[\tau, T]$ to a solution $u : [\tau, T] \to \mathbb{K}$ of (1.1.1). Clearly $u(\tau) = \xi$.

In the fifth step, we show that $u([s, T]) \subset \mathcal{P}(u(s))$ for all $s \in S$. Indeed, given s as above, there exists $k \in \mathbb{N}$ such that $s \in S_k$. Then $s \in S_m$ and $u_m([s, T]) \subseteq \mathcal{P}(u_m(s))$ for all $m \in \mathbb{N}$ with $k \leqslant m$. At this point, the closedness of the graph of $\mathcal{P}$ shows that $u([s, T]) \subset \mathcal{P}(u(s))$.

In the sixth and final step, taking into account that S is dense in $[\tau, T]$, u is continuous on $[\tau, T]$ and the graph of $\mathcal{P}$ is closed, we conclude that the preceding relation holds for every $s \in [\tau, T]$, and this completes the proof. □

THEOREM 3.8.1. *Let $\mathcal{P}$ be a closed preorder on $\mathbb{K}$ and let $f : \mathbb{I} \times \mathbb{K} \to \mathbb{R}^n$ be continuous. Then a necessary and sufficient condition in order that $\mathcal{P}$ be viable with respect to f is the tangency condition below*:

$$f(t,\xi) \in \mathcal{T}_{\mathcal{P}(\xi)}(\xi)$$

for each $(t,\xi) \in \mathbb{I} \times \mathbb{K}$.

PROOF. The proof follows immediately from Lemma 3.8.1. □

4. Problems of invariance

This section follows very closely Cârjă et al. [24].

4.1. *Preliminary facts*

Let $\mathbb{D}$ be a domain in $\mathbb{R}^n$, $\mathbb{K} \subseteq \mathbb{D}$ a locally closed subset, and let us consider the ordinary differential equation (1.1.1), where $f : \mathbb{I} \times \mathbb{D} \to \mathbb{R}^n$ is a given function.

DEFINITION 4.1.1. The subset $\mathbb{K}$ is *locally invariant* with respect to f if for each $(\tau,\xi) \in \mathbb{I} \times \mathbb{K}$ and each solution $u : [\tau, c] \to \mathbb{D}$, $c \in \mathbb{I}$, $c > \tau$, of (1.1.1), satisfying the initial condition $u(\tau) = \xi$, there exists $T \in (\tau, c]$ such that $u(t) \in \mathbb{K}$ for each $t \in [\tau, T]$. It is *invariant* if it satisfies the above condition of local invariance with $T = c$.

The relationship between viability and local invariance is clarified in

REMARK 4.1.1. If f is continuous on $\mathbb{I} \times \mathbb{D}$ and $\mathbb{K}$ is locally invariant with respect to f, then $\mathbb{K}$ is viable with respect to f. The converse of this assertion is no longer true, as we can see from the following example.

EXAMPLE 4.1.1. Let $\mathbb{D} = \mathbb{R}$, $\mathbb{K} = \{0\}$ and let $f : \mathbb{R} \to \mathbb{R}$ be defined by $f(u) = 3\sqrt[3]{u^2}$ for every $u \in \mathbb{R}$. Then $\mathbb{K}$ is viable with respect to f but $\mathbb{K}$ is not locally invariant with respect to f, because the differential equation $u'(t) = f(u(t))$ has at least two solutions which satisfy $u(0) = 0$, i.e. $u \equiv 0$ and $v(t) = t^3$.

A simple necessary and sufficient condition of invariance is stated below.

THEOREM 4.1.1. *Let $\mathbb{D}$ be a domain, $\mathbb{K} \subseteq \mathbb{D}$ a nonempty and locally closed subset and $f : \mathbb{I} \times \mathbb{D} \to \mathbb{R}^n$ a continuous function with the property that the associated Cauchy problem has the uniqueness property. Then, a necessary and sufficient condition in order that $\mathbb{K}$ be invariant with respect to f is that, for every $(t,\xi) \in \mathbb{I} \times \mathbb{K}$, $f(t,\xi) \in \mathcal{T}_{\mathbb{K}}(\xi)$.*

PROOF. The conclusion follows from Theorem 3.1.1 and Remark 4.1.1. □

Theorem 4.1.1 says that, in general, if $\mathbb{K}$ is viable with respect to $f_{|\mathbb{I}\times\mathbb{K}}$ and (1.1.1) has the uniqueness property, then $\mathbb{K}$ is locally invariant with respect to f. The preceding example shows that this is no longer true if we assume that $\mathbb{K}$ is viable with respect to f and merely $u'(t) = f_{|\mathbb{I}\times\mathbb{K}}(t, u(t))$ has the uniqueness property.

REMARK 4.1.2. Moreover, if $f:\mathbb{I}\times\mathbb{D}\to\mathbb{R}^n$ is continuous and there exists one and only one point $\xi\in\mathbb{D}$ such that the differential equation (1.1.1) has at least two solutions u and v satisfying $u(\tau)=v(\tau)=\xi$, then, $\mathbb{K}=\{u(t);\ t\in[\tau,T]\}$ is viable with respect to f but it is not locally invariant with respect to f.

The next example reveals another interesting fact about local invariance. It shows that the local invariance of $\mathbb{K}$ with respect to f can take place even if $u'(t)=f_{|\mathbb{I}\times\mathbb{K}}(t,u(t))$ has not the uniqueness property.

EXAMPLE 4.1.2. Let $\mathbb{K}=\{(x,y)\in\mathbb{R}^2;\ y\geqslant 0\}$ and let $f:\mathbb{R}^2\to\mathbb{R}^2$ be defined by

$$f\big((x,y)\big)=\begin{cases}(1,0) & \text{if } (x,y)\in\mathbb{R}^2\setminus\mathbb{K},\\ \big(1,3\sqrt[3]{y^2}\big) & \text{if } (x,y)\in\mathbb{K}.\end{cases}$$

Obviously $\mathbb{K}$ is locally invariant with respect to $f_{|\mathbb{K}}$ but $u'(t)=f_{|\mathbb{K}}(u(t))$ has not the uniqueness property. The latter assertion follows from the remark that, from each point, $(x,0)$ (on the boundary of $\mathbb{K}$), we have at least two solutions to $u'(t)=f(u(t))$, $u(t)=(t+x,0)$ and $v(t)=(t+x,t^3)$ satisfying $u(0)=v(0)=(x,0)$.

4.2. *Sufficient conditions for local invariance*

Our first sufficient condition for local invariance says that, whenever there exists an open neighborhood $\mathbb{V}\subseteq\mathbb{D}$ of $\mathbb{K}$ such that f satisfies the "exterior tangency" condition

$$\liminf_{h\downarrow 0}\frac{1}{h}\big[\operatorname{dist}\big(\xi+hf(t,\xi);\mathbb{K}\big)-\operatorname{dist}(\xi;\mathbb{K})\big]\leqslant\omega\big(t,\operatorname{dist}(\xi;\mathbb{K})\big)\tag{4.2.1}$$

for each $(t,\xi)\in\mathbb{I}\times\mathbb{V}$, where ω is a comparison function in the sense of Definition 3.7.1, then $\mathbb{K}$ is locally invariant with respect to f. More precisely, we have:

THEOREM 4.2.1. *Let $\mathbb{K}\subseteq\mathbb{D}\subseteq\mathbb{R}^n$, with $\mathbb{K}$ locally closed and $\mathbb{D}$ open, and let $f:\mathbb{I}\times\mathbb{D}\to\mathbb{R}^n$. If* (4.2.1) *is satisfied, then $\mathbb{K}$ is locally invariant with respect to f.*

PROOF. Let $\mathbb{V}\subseteq\mathbb{D}$ be the open neighborhood of $\mathbb{K}$ whose existence is ensured by (4.2.1), and let $\omega:\mathbb{I}\times[0,a)\to\mathbb{R}$ the corresponding comparison function. Let $\xi\in\mathbb{K}$ and let $u:[\tau,c]\to\mathbb{V}$ be any solution to (1.1.1) satisfying $u(\tau)=\xi$. Diminishing c if necessary, we may assume that there exists $\rho>0$ such that $B(\xi,\rho)\cap\mathbb{K}$ is closed, $u(t)\in B(\xi,\rho/2)$ and, in addition, $\operatorname{dist}(u(t);\mathbb{K})<a$ for each $t\in[\tau,c]$. Let $g:[\tau,c]\to\mathbb{R}_+$ be defined by $g(t)=\operatorname{dist}(u(t);\mathbb{K})$ for each $t\in[\tau,c]$. Let $t\in[\tau,c)$ and $h>0$ with $t+h\in[\tau,c]$. We have

$$\begin{aligned}g(t+h)&=\operatorname{dist}\big(u(t+h);\mathbb{K}\big)\\&\leqslant h\left\|\frac{u(t+h)-u(t)}{h}-u'(t)\right\|+\operatorname{dist}\big(u(t)+hu'(t);\mathbb{K}\big).\end{aligned}$$

Therefore

$$\frac{g(t+h)-g(t)}{h} \leqslant \alpha(h) + \frac{\operatorname{dist}(u(t)+hu'(t);\mathbb{K}) - \operatorname{dist}(u(t);\mathbb{K})}{h},$$

where

$$\alpha(h) = \left\| \frac{u(t+h)-u(t)}{h} - u'(t) \right\|.$$

Since $u'(t) = f(t, u(t))$ and $\lim_{h\downarrow 0} \alpha(h) = 0$, passing to the inf-limit in the inequality above for $h \downarrow 0$, and taking into account that $\mathbb{V}$, $\mathbb{K}$, and f satisfy (4.2.1), we get

$$[D_+ g](t) \leqslant \omega\big(t, g(t)\big)$$

for each $t \in [\tau, c)$. So, $g(t) \equiv 0$ which means that $u(t) \in \overline{\mathbb{K}} \cap B(\xi, \rho/2)$. But $\overline{\mathbb{K}} \cap B(\xi, \rho/2) \subseteq \mathbb{K} \cap B(\xi, \rho)$, and this achieves the proof. □

REMARK 4.2.1. Clearly, (4.2.1) is satisfied with $\omega = \omega_f$, where the function $\omega_f : \mathbb{I} \times [0, a) \to \overline{\mathbb{R}}$, $a = \sup_{\xi\in\mathbb{V}} \operatorname{dist}(\xi;\mathbb{K})$ is defined by

$$\omega_f(t,x) = \sup_{\substack{\xi\in\mathbb{V} \\ \operatorname{dist}(\xi;\mathbb{K})=x}} \liminf_{h\downarrow 0} \frac{1}{h}\big[\operatorname{dist}\big(\xi + hf(t,\xi);\mathbb{K}\big) - \operatorname{dist}(\xi;\mathbb{K})\big] \tag{4.2.2}$$

for each $(t, x) \in \mathbb{I} \times [0, a)$.

So, Theorem 4.2.1 can be reformulated as:

THEOREM 4.2.2. *Let $\mathbb{K} \subseteq \mathbb{D} \subseteq \mathbb{R}^n$, with $\mathbb{K}$ locally closed and $\mathbb{D}$ open, and let $f : \mathbb{I} \times \mathbb{D} \to \mathbb{R}^n$. If there exists an open neighborhood $\mathbb{V}$ of $\mathbb{K}$ with $\mathbb{V} \subseteq \mathbb{D}$ such that ω_f defined by* (4.2.2) *is a comparison function, then $\mathbb{K}$ is locally invariant with respect to f.*

4.3. *Viability and comparison imply exterior tangency*

DEFINITION 4.3.1. Let $\mathbb{K} \subseteq \mathbb{D} \subseteq \mathbb{R}^n$. We say that a function $f : \mathbb{I} \times \mathbb{D} \to \mathbb{R}^n$ has *the comparison property with respect to* $(\mathbb{D}, \mathbb{K})$ if there exist a proximal neighborhood $\mathbb{V} \subseteq \mathbb{D}$ of $\mathbb{K}$, one projection $\pi_{\mathbb{K}} : \mathbb{V} \to \mathbb{K}$ subordinated to $\mathbb{V}$, and one comparison function $\omega : \mathbb{I} \times [0, a) \to \mathbb{R}$, with $a = \sup_{\xi\in\mathbb{V}} \operatorname{dist}(\xi;\mathbb{K})$, such that

$$\big[\xi - \pi_{\mathbb{K}}(\xi), f(t,\xi) - f\big(t, \pi_{\mathbb{K}}(\xi)\big)\big]_+ \leqslant \omega\big(t, \|\xi - \pi_{\mathbb{K}}(\xi)\|\big) \tag{4.3.1}$$

for each $(t, \xi) \in \mathbb{I} \times \mathbb{V}$.

Let us observe that (4.3.1) is automatically satisfied for each $(t,\xi)\in\mathbb{I}\times\mathbb{K}$, and therefore, in Definition 4.3.1, we have only to assume that (4.3.1) holds for each $(t,\xi)\in\mathbb{I}\times[\mathbb{V}\setminus\mathbb{K}]$.

DEFINITION 4.3.2. The function $f:\mathbb{I}\times\mathbb{D}\to\mathbb{R}^n$ is called:

(i) $(\mathbb{D},\mathbb{K})$-*Lipschitz* if there exist a proximal neighborhood $\mathbb{V}\subseteq\mathbb{D}$ of $\mathbb{K}$, a subordinated projection $\pi_{\mathbb{K}}:\mathbb{V}\to\mathbb{K}$, and $L>0$, such that

$$\left\|f(t,\xi)-f\big(t,\pi_{\mathbb{K}}(\xi)\big)\right\|\leqslant L\left\|\xi-\pi_{\mathbb{K}}(\xi)\right\|$$

for each $(t,\xi)\in\mathbb{I}\times[\mathbb{V}\setminus\mathbb{K}]$;

(ii) $(\mathbb{D},\mathbb{K})$-*dissipative* if there exist a proximal neighborhood $\mathbb{V}\subseteq\mathbb{D}$ of $\mathbb{K}$, and a projection, $\pi_{\mathbb{K}}:\mathbb{V}\to\mathbb{K}$, subordinated to $\mathbb{V}$, such that

$$\big[\xi-\pi_{\mathbb{K}}(\xi),\,f(t,\xi)-f\big(t,\pi_{\mathbb{K}}(\xi)\big)\big]_+\leqslant 0$$

for each $(t,\xi)\in\mathbb{I}\times[\mathbb{V}\setminus\mathbb{K}]$.

REMARK 4.3.1. We notice that, if we assume that (4.3.1), or either of the conditions (i), or (ii) in Definition 4.3.2 is satisfied for ξ replaced by ξ_1 and $\pi_{\mathbb{K}}(\xi)$ replaced by ξ_2 with $\xi_1,\xi_2\in\mathbb{V}$, as considered in Kenmochi and Takahashi [60], then, for each $[\tau,T]\subseteq\mathbb{I}$ and $\xi\in\mathbb{K}$, there exists at most one solution $u:[\tau,T]\to\mathbb{K}$ to (1.1.1) satisfying $u(\tau)=\xi$. On contrary, in this more general frame, it may happen that, for certain (or for all) $[\tau,T]\subseteq\mathbb{I}$ and $\xi\in\mathbb{K}$, (1.1.1) have at least two solutions $u,v:[\tau,T]\to\mathbb{K}$ satisfying $u(\tau)=v(\tau)=\xi$.

Let $\mathbb{V}$ be a proximal neighborhood of $\mathbb{K}$, and let $\pi_{\mathbb{K}}:\mathbb{V}\to\mathbb{K}$ be a projection subordinated to $\mathbb{V}$. If $f:\mathbb{I}\times\mathbb{V}\to\mathbb{K}$ is a function with the property that, for each $t\in\mathbb{I}$ and $\eta\in\mathbb{K}$, the restriction of $f(t,\cdot)$ to the "segment"

$$\mathbb{V}_\eta=\big\{\xi\in\mathbb{V}\setminus\mathbb{K};\ \pi_{\mathbb{K}}(\xi)=\eta\big\}$$

is dissipative, then f is $(\mathbb{D},\mathbb{K})$-dissipative.

It is easy to see that if f is either $(\mathbb{D},\mathbb{K})$-Lipschitz, or $(\mathbb{D},\mathbb{K})$-dissipative, then it has the comparison property with respect to $(\mathbb{D},\mathbb{K})$. We notice that there are examples showing that there exist functions f which, although neither $(\mathbb{D},\mathbb{K})$-Lipschitz, nor $(\mathbb{D},\mathbb{K})$-dissipative, do have the comparison property. Moreover, there exist functions which, although $(\mathbb{D},\mathbb{K})$-Lipschitz, are not Lipschitz on $\mathbb{D}$, as well as, functions which although $(\mathbb{D},\mathbb{K})$-dissipative, are not dissipative on $\mathbb{D}$. In fact, these two properties describe merely the local behavior of f at the interface between $\mathbb{K}$ and $\mathbb{D}\setminus\mathbb{K}$. We include below two examples: the first one of an $(\mathbb{D},\mathbb{K})$-Lipschitz function which is not locally Lipschitz, and the second one of a function which, although non-dissipative, is $(\mathbb{D},\mathbb{K})$-dissipative. We notice that both examples refer to the autonomous case.

EXAMPLE 4.3.1. The graph of an $(\mathbb{D},\mathbb{K})$-Lipschitz function $f:\mathbb{R}\to\mathbb{R}$ which is not Lipschitz is illustrated in Fig. 2. Here $\mathbb{K}=[a,b]$ and $\mathbb{D}$ is any open subset in $\mathbb{R}$ including $\mathbb{K}$.

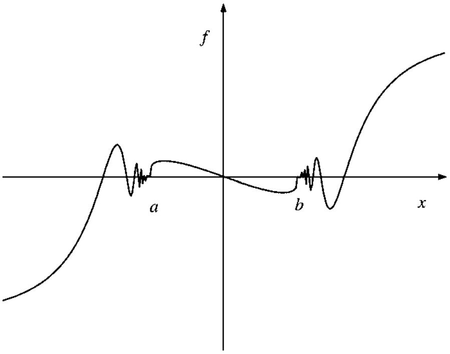


Fig. 2.

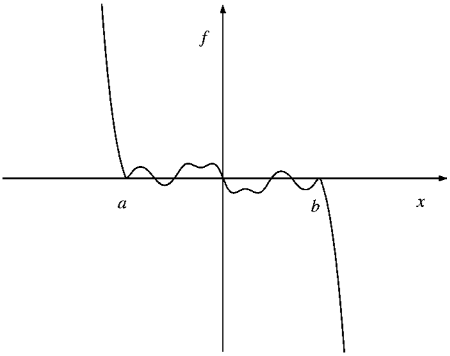

Fig. 3.

EXAMPLE 4.3.2. The graph of a function $f:\mathbb{R}\to\mathbb{R}$ which is $(\mathbb{D},\mathbb{K})$-dissipative but not dissipative is illustrated in Fig. 3. This time, $\mathbb{K}$ is either $(-\infty,\beta]$, or $[\alpha,+\infty)$, or $[\alpha,\beta]$ with $\alpha\leqslant a\leqslant b\leqslant\beta$, and $\mathbb{D}$ is any open subset in $\mathbb{R}$ including $\mathbb{K}$.

We begin with:

THEOREM 4.3.1. *Let* $\mathbb{K}\subseteq\mathbb{D}\subseteq\mathbb{R}^n$, *with* $\mathbb{K}$ *locally closed and* $\mathbb{D}$ *open, and let* $f:\mathbb{I}\times\mathbb{D}\to\mathbb{R}^n$. *If* f *has the comparison property with respect to* $(\mathbb{D},\mathbb{K})$, *and* (1.1.3) *is satisfied, then* (4.2.1) *holds true.*

PROOF. Let $\mathbb{V}\subseteq\mathbb{D}$ be the open neighborhood of $\mathbb{K}$ as in Definition 4.3.1, let $\xi\in\mathbb{V}$ and $[t,T)\subseteq\mathbb{I}$. Let $\rho>0$ and let $\pi_{\mathbb{K}}$ be the selection of $\Pi_{\mathbb{K}}$ as in Definition 4.3.1. Let $h>0$ with $t+h\in[t,T]$. Taking into account that $\|\xi-\pi_{\mathbb{K}}(\xi)\|=\operatorname{dist}(\xi;\mathbb{K})$, we have

$$\begin{aligned}&\operatorname{dist}\bigl(\xi+hf(t,\xi);\mathbb{K}\bigr)-\operatorname{dist}(\xi;\mathbb{K})\\&\quad\leqslant\bigl\|\xi-\pi_{\mathbb{K}}(\xi)+h\bigl[f(t,\xi)-f\bigl(t,\pi_{\mathbb{K}}(\xi)\bigr)\bigr]\bigr\|\end{aligned}$$

$$-\left\|\xi-\pi_{\mathbb{K}}(\xi)\right\|+\operatorname{dist}\bigl(\pi_{\mathbb{K}}(\xi)+hf\bigl(t,\pi_{\mathbb{K}}(\xi)\bigr);\mathbb{K}\bigr).$$

Dividing by h, passing to the inf-limit for $h\downarrow 0$, and using (1.1.3), we get

$$\begin{aligned}&\liminf_{h\downarrow 0}\frac{1}{h}\bigl[\operatorname{dist}\bigl(\xi+hf(t,\xi);\mathbb{K}\bigr)-\operatorname{dist}(\xi;\mathbb{K})\bigr]\\&\quad\leqslant\bigl[\xi-\pi_{\mathbb{K}}(\xi),f(t,\xi)-f\bigl(t,\pi_{\mathbb{K}}(\xi)\bigr)\bigr]_{+}\\&\quad\leqslant\omega\bigl(t,\left\|\xi-\pi_{\mathbb{K}}(\xi)\right\|\bigr).\end{aligned}$$

But this inequality shows that (4.2.1) holds, and this completes the proof. □

In the specific case in which f is continuous, we have:

THEOREM 4.3.2. *Let $\mathbb{K}\subseteq\mathbb{D}\subseteq\mathbb{R}^n$, with $\mathbb{K}$ locally closed and $\mathbb{D}$ open, and let $f:\mathbb{I}\times\mathbb{D}\to\mathbb{R}^n$ be continuous. Let us assume that f has the comparison property with respect to* $(\mathbb{D},\mathbb{K})$*, and one of the four conditions below is satisfied*:

(i) *for every $(t,\xi)\in\mathbb{I}\times\mathbb{K}$, $f(t,\xi)\in\mathcal{C}_{\mathbb{K}}(\xi)$,*
(ii) *for every $(t,\xi)\in\mathbb{I}\times\mathbb{K}$, $f(t,\xi)\in\mathcal{T}_{\mathbb{K}}(\xi)$,*
(iii) *for every $(t,\xi)\in\mathbb{I}\times\mathbb{K}$, $f(t,\xi)\in\mathcal{B}_{\mathbb{K}}(\xi)$,*
(iv) *the set $\mathbb{K}$ is viable with respect to f.*

Then (4.2.1) *is also satisfied.*

In general, if $\mathcal{G}:\mathbb{K}\rightsquigarrow\mathbb{R}^n$ satisfies $\mathcal{C}_{\mathbb{K}}(\xi)\subseteq\mathcal{G}(\xi)\subseteq\mathcal{B}_{\mathbb{K}}(\xi)$ for each $\xi\in\mathbb{K}$ and:

(v) *for every $(t,\xi)\in\mathbb{I}\times\mathbb{K}$, $f(t,\xi)\in\mathcal{G}(\xi)$,*

then (4.2.1) *is satisfied too.*

PROOF. The conclusion follows from Theorem 3.4.1. □

4.4. *Sufficient conditions for invariance. Revisited*

The next sufficient condition for invariance follows from Theorems 4.2.1 and 4.3.2.

THEOREM 4.4.1. *Let $\mathbb{K}\subseteq\mathbb{D}\subseteq\mathbb{R}^n$, with $\mathbb{K}$ locally closed and $\mathbb{D}$ open, and let $f:\mathbb{I}\times\mathbb{D}\to\mathbb{R}^n$. If f has the comparison property with respect to* $(\mathbb{D},\mathbb{K})$*, and satisfies one of the conditions* (i), (ii), (iii), *or* (v) *in Theorem* 4.3.2, *then $\mathbb{K}$ is locally invariant with respect to f.*

Now, let $\mathbb{K}\subseteq\mathbb{R}^n$ and let $\mathbb{V}$ be an open neighborhood of $\mathbb{K}$.

DEFINITION 4.4.1. A function $g:\mathbb{V}\to\mathbb{K}$ is *a proximal generalized distance* if:

(i) g is Lipschitz continuous on bounded subsets in $\mathbb{V}$,
(ii) $g(\xi)=0$ if and only if $\xi\in\mathbb{K}$.

If $\mathbb{K}$ is closed, a typical example of proximal generalized distance is offered by $g(\xi) = \alpha(\operatorname{dist}(\xi;\mathbb{K}))$, where $\alpha : [0,+\infty) \to [0,+\infty)$ is Lipschitz on bounded subsets, $\alpha(0) = 0$ and $\alpha(r) \neq 0$ if $r \neq 0$, while $\operatorname{dist}(\xi;\mathbb{K})$ is the usual distance from ξ to $\mathbb{K}$. We notice that if there exists a proximal generalized distance $g : \mathbb{V} \to [0,+\infty)$, then $\mathbb{K}$ is locally closed. Indeed, since $\mathbb{K} = \{\xi \in \mathbb{V};\ g(\xi) = 0\}$ and g is continuous, $\mathbb{K}$ is relatively closed in $\mathbb{V}$. But $\mathbb{V}$ is open and thus $\mathbb{K}$ is locally closed, as claimed.

THEOREM 4.4.2. *Let $\mathbb{K} \subseteq \mathbb{D} \subseteq \mathbb{R}^n$, and let $f : \mathbb{I} \times \mathbb{D} \to \mathbb{R}^n$. If there exist an open neighborhood $\mathbb{V}$ of $\mathbb{K}$, with $\mathbb{V} \subseteq \mathbb{D}$, a proximal generalized distance $g : \mathbb{V} \to \mathbb{R}_+$ and a comparison function $\omega : \mathbb{I} \times [0,a) \to \mathbb{R}$ such that*

$$\liminf_{h \downarrow 0} \frac{1}{h}\big[g\big(\xi + hf(t,\xi)\big) - g(\xi)\big] \leqslant \omega\big(t, g(\xi)\big) \tag{4.4.1}$$

for each $(t,\xi) \in \mathbb{I} \times \mathbb{V}$, then $\mathbb{K}$ is locally invariant with respect to f.

PROOF. The proof follows closely that one of Theorem 4.2.1, with the mention that here one has to use the obvious inequality $g(\lambda) \leqslant g(\eta) + L\|\lambda - \eta\|$ for each $\lambda, \eta \in B(\xi,\rho) \cap \mathbb{V}$, where $L > 0$ is the Lipschitz constant of g on $B(\xi,\rho) \cap \mathbb{V}$. □

In order to obtain a simple, but useful, extension of Theorem 4.2.1, some observations are needed. Namely, if $g : \mathbb{V} \to [0,+\infty)$ is a generalized distance, we may consider the generalized tangency condition

$$\liminf_{h \downarrow 0} \frac{1}{h} g\big(\xi + hf(t,\xi)\big) = 0 \tag{4.4.2}$$

for each $(t,\xi) \in \mathbb{I} \times \mathbb{K}$, and one may ask whether this implies viability, whenever, of course f is continuous. The answer to this question is in the negative as the simple example below shows.

EXAMPLE 4.4.1. Let $\mathbb{K}$ be locally closed, let $\mathbb{V}$ be any open neighborhood of $\mathbb{K}$ and let $g : \mathbb{V} \to [0,+\infty)$ be defined as $g(\xi) = \operatorname{dist}^2(\xi;\mathbb{K})$ for each $\xi \in \mathbb{V}$. Further, let $f : \mathbb{I} \times \mathbb{K} \to \mathbb{R}^n$ be a continuous function such that $\mathbb{K}$ is not viable with respect to f. We can always find such a function whenever $\mathbb{K}$ is not open. Now, since

$$g\big(\xi + hf(t,\xi)\big) \leqslant \big\|\xi + hf(t,\xi) - \xi\big\|^2 \leqslant h^2\big\|f(t,\xi)\big\|^2$$

for each $(t,\xi) \in \mathbb{I} \times \mathbb{K}$, (4.4.2) is trivially satisfied. So, the generalized tangency condition (4.4.2) does not imply the viability of $\mathbb{K}$ with respect to f.

This example shows that if g is a proximal generalized distance, and g^2 satisfies (4.4.2), it may happen that g does not satisfy (4.4.2). Therefore it justifies why, in the next result, we assume explicitly that (4.4.2) holds true, even though it is automatically satisfied by g^2.

THEOREM 4.4.3. *Let* $\mathbb{K} \subseteq \mathbb{D} \subseteq \mathbb{R}^n$, *and let* $f : \mathbb{I} \times \mathbb{D} \to \mathbb{R}^n$. *If there exist an open neighborhood* $\mathbb{V}$ *of* $\mathbb{K}$, *with* $\mathbb{V} \subseteq \mathbb{D}$, *and a proximal generalized distance* $g : \mathbb{V} \to \mathbb{R}_+$ *satisfying* (4.4.2) *and such that*

$$\liminf_{h \downarrow 0} \frac{1}{2h} \big[g^2\big(\xi + hf(t, \xi)\big) - g^2(\xi) \big] \leqslant g(\xi)\omega\big(t, g(\xi)\big) \tag{4.4.3}$$

for each $(t, \xi) \in \mathbb{I} \times \mathbb{V}$, *then* $\mathbb{K}$ *is locally invariant with respect to* f.

PROOF. We have only to observe that, in the presence of (4.4.2), (4.4.3) and (4.4.1) are equivalent, and to apply Theorem 4.4.2. □

Using Theorem 4.4.3, we will prove next some other sufficient conditions for invariance expressed in the terms of a generalized Lipschitz projection. Namely, a subset $\mathbb{K}$ is a *Lipschitz retract* if there exist an open neighborhood $\mathbb{V}$ of $\mathbb{K}$ and a Lipschitz continuous map, $r : \mathbb{V} \to \mathbb{K}$, with $r(\xi) = \xi$ if and only if $\xi \in \mathbb{K}$. The function r as above is a *generalized Lipschitz projection*. For each Lipschitz retract $\mathbb{K}$, one can define a proximal generalized distance, $g : \mathbb{V} \to [0, +\infty)$, by $g(\xi) = \|r(\xi) - \xi\|$ for all $\xi \in \mathbb{V}$. Consequently, each Lipschitz retract is locally closed. Moreover, each open subset $\mathbb{K}$ is Lipschitz retract (take $\mathbb{V} = \mathbb{K}$ and r the identity). Another simple example of a Lipschitz retract is given by a closed subset $\mathbb{K}$ which has an open neighborhood $\mathbb{V}$ for which there exists a single-valued continuous projection $\pi_{\mathbb{K}} : \mathbb{V} \to \mathbb{K}$, i.e. $\operatorname{dist}(\xi; \mathbb{K}) = \|\pi_{\mathbb{K}}(\xi) - \xi\|$ for each $\xi \in \mathbb{V}$. In the latter case we say that $\mathbb{K}$ is *a proximate retract*. It should be noticed that the class of Lipschitz retract subsets is strictly larger than that of proximate retracts as the simple example below shows.

EXAMPLE 4.4.2. Take $\mathbb{R}^2$, endowed with the usual Hilbert structure and let us observe that the set

$$\mathbb{K} = \big\{(x, y) \in \mathbb{R}^2;\ y \leqslant |x|\big\},$$

although Lipschitz retract, is not a proximate retract. Indeed, let $\mathbb{V} = \mathbb{R}^2$, and let $r((x, y))$ be defined, either as (x, y) if $(x, y) \in \mathbb{K}$, or as $(x, |x|)$ if $(x, y) \in \mathbb{V} \setminus \mathbb{K}$. It is easy to verify that r is a generalized Lipschitz projection with Lipschitz constant $\sqrt{2}$, and thus $\mathbb{K}$ is a Lipschitz retract. However, $\mathbb{K}$ is not a proximate retract since any selection $\pi_{\mathbb{K}}$ of the projection $\Pi_{\mathbb{K}}$ is discontinuous at each point $(0, y)$, with $y > 0$.

We emphasize that all the results which will follow can be reformulated to hold also for locally Lipschitz retracts, i.e. for those subsets $\mathbb{K}$ satisfying: *for each* $\xi \in \mathbb{K}$ *there exists* $\rho > 0$ *such that* $B(\xi; \rho) \cap \mathbb{K}$ *is Lipschitz retract*, but for the sake of simplicity we confined ourselves to the simpler case of Lipschitz retracts. First, let $\mathbb{K}$ be Lipschitz retract with the corresponding generalized Lipschitz projection $r : \mathbb{V} \to \mathbb{K}$. In the next two results, we will assume that the norm on $\mathbb{R}^n$ is defined by means of an inner product, i.e. $\|x\|^2 = \langle x, x\rangle$ for each $x \in \mathbb{R}^n$.

THEOREM 4.4.4. *Let $\mathbb{D} \subseteq \mathbb{R}^n$ be open and let $f : \mathbb{I} \times \mathbb{D} \to \mathbb{R}^n$. Let us assume that $\mathbb{K} \subseteq \mathbb{D}$ is Lipschitz retract with generalized Lipschitz projection $r : \mathbb{V} \to \mathbb{K}$ satisfying*

$$\liminf_{h\downarrow 0} \frac{1}{h} \big\| r\big(\xi + hf(t,\xi)\big) - \xi - hf(t,\xi)\big\| = 0 \tag{4.4.4}$$

for each $(t,\xi) \in \mathbb{I} \times \mathbb{K}$. Assume, in addition, that there exists a comparison function $\omega : \mathbb{I} \times [0,a) \to \mathbb{R}$, with $a = \sup_{\xi\in\mathbb{V}} \|r(\xi) - \xi\|$ such that

$$\begin{aligned}&\liminf_{h\downarrow 0} \frac{1}{h} \big\langle r\big(\xi + hf(t,\xi)\big) - r(\xi) - hf(t,\xi), r(\xi) - \xi\big\rangle \\ &\quad\leqslant \big\|r(\xi) - \xi\big\| \omega\big(t, \big\|r(\xi) - \xi\big\|\big)\end{aligned} \tag{4.4.5}$$

for each $(t,\xi) \in \mathbb{I} \times \mathbb{V}$. Then $\mathbb{K}$ is locally invariant with respect to f.

PROOF. Let us define $g(\xi) = \|r(\xi) - \xi\|$ for each $\xi \in \mathbb{V}$, and let $L > 0$ be the Lipschitz constant of r. Let us observe that

$$\begin{aligned}&g^2(\xi + h\eta) - g^2(\xi) \\ &\quad= \big\langle r(\xi + h\eta) - (\xi + h\eta) - \big(r(\xi) - \xi\big), r(\xi + h\eta) - (\xi + h\eta) + \big(r(\xi) - \xi\big)\big\rangle \\ &\quad= \big\langle r(\xi + h\eta) - r(\xi), r(\xi + h\eta) + r(\xi) - 2\xi\big\rangle \\ &\qquad - h\big\langle \eta, 2r(\xi + h\eta) - 2\xi\big\rangle + h^2\|\eta\|^2 \\ &\quad= \big\|r(\xi + h\eta) - r(\xi)\big\|^2 + 2\big\langle r(\xi + h\eta) - r(\xi), r(\xi) - \xi\big\rangle \\ &\qquad - h\big\langle \eta, 2r(\xi + h\eta) - 2\xi\big\rangle + h^2\|\eta\|^2 \\ &\quad\leqslant \big(L^2 + 1\big)h^2\|\eta\|^2 + 2\big\langle r(\xi + h\eta) - r(\xi), r(\xi) - \xi\big\rangle - 2h\big\langle \eta, r(\xi + h\eta) - \xi\big\rangle.\end{aligned}$$

Therefore,

$$\begin{aligned}&\liminf_{h\downarrow 0} \frac{1}{2h} \big[g^2(\xi + h\eta) - g^2(\xi)\big] \\ &\quad\leqslant \liminf_{h\downarrow 0} \frac{1}{h} \big\langle r(\xi + h\eta) - r(\xi), r(\xi) - \xi\big\rangle - \big\langle \eta, r(\xi) - \xi\big\rangle.\end{aligned}$$

Since, by (4.4.4), g satisfies (4.4.2), taking $\eta = f(t,\xi)$ and using (4.4.5) and Theorem 4.4.3, we get the conclusion. □

A consequence of Theorem 4.4.4 is stated below.

THEOREM 4.4.5. *Let $\mathbb{K} \subseteq \mathbb{D}$, with $\mathbb{D}$ open, and let $f : \mathbb{I} \times \mathbb{D} \to \mathbb{R}^n$. Let us assume that $\mathbb{K}$ is a Lipschitz retract with the generalized Lipschitz projection $r : \mathbb{V} \to \mathbb{K}$ satisfying* (4.4.4).

Let us assume in addition that, for each $t \in \mathbb{I}$ and $\xi \in \mathbb{V}$, there exists the directional derivative, $r'(\xi)[f(t,\xi)]$, of r, at ξ in the direction $f(t,\xi)$, and

$$\big\langle r'(\xi)\big[f(t,\xi)\big] - f(t,\xi), r(\xi) - \xi\big\rangle \leqslant \big\|r(\xi) - \xi\big\|\omega\big(t, \big\|r(\xi) - \xi\big\|\big), \tag{4.4.6}$$

where $\omega : \mathbb{I} \times [0, a) \to \mathbb{R}$ is a comparison function, and $a = \sup_{\xi \in \mathbb{V}} \|r(\xi) - \xi\|$. Then $\mathbb{K}$ is locally invariant with respect to f.

PROOF. It is easy to see that, in this specific case, (4.4.6) is equivalent to (4.4.5) and this completes the proof. □

REMARK 4.4.1. Let $\mathbb{K}$ be a Lipschitz retract subset and let $r : \mathbb{V} \to \mathbb{K}$ be the corresponding generalized Lipschitz projection. Let $f : \mathbb{I} \times \mathbb{K} \to \mathbb{R}^n$ be a continuous function, let $a = \sup_{\xi \in \mathbb{V}} \|r(\xi) - \xi\|$, and let us define the function $\omega : \mathbb{I} \times [0, a) \to \overline{\mathbb{R}}_+$ by $\omega(t, 0) = 0$ and

$$\omega(t,x) = \sup_{\substack{\xi \in \mathbb{V} \\ \|r(\xi)-\xi\|=x}} \frac{\langle r'(\xi)[f(t,\xi)] - f(t,\xi), r(\xi) - \xi\rangle}{\|r(\xi) - \xi\|} \tag{4.4.7}$$

for each $(t,x) \in \mathbb{I} \times (0,a)$. From Theorem 4.4.5, it follows that $\mathbb{K}$ is invariant with respect to f if (4.4.4) is satisfied and ω, defined by (4.4.7), is a comparison function. Furthermore, if $\mathbb{K} \subseteq \mathbb{R}^n$ is a closed linear subspace in $\mathbb{R}^n$, and r is the projection of $\mathbb{R}^n$ on $\mathbb{K}$, then r is linear, and $r'(\xi)[\eta] = r(\eta)$ for each $\xi, \eta \in \mathbb{R}^n$. So, in this case, the condition (4.4.4) is equivalent to $f(\mathbb{I} \times \mathbb{K}) \subseteq \mathbb{K}$. Take $\mathbb{V} = \{\xi \in \mathbb{R}^n;\ \operatorname{dist}(\xi; \mathbb{K}) < \rho\}$, for some fixed $\rho > 0$, and let us observe that the function ω, defined by (4.4.7), is given by $\omega(t,0) = 0$ and

$$\omega(t,x) = \sup_{\substack{\xi \in \mathbb{V} \\ \|r(\xi)-\xi\|=x}} \frac{\langle r(f(t,\xi)) - f(t,\xi), r(\xi) - \xi\rangle}{\|r(\xi) - \xi\|} \tag{4.4.8}$$

for each $(t,x) \in \mathbb{I} \times (0,\rho)$. Hence, if $f(\mathbb{I} \times \mathbb{K}) \subseteq \mathbb{K}$, and ω defined by (4.4.8) is a comparison function, then $\mathbb{K}$ is invariant with respect to (1.1.1).

4.5. *When tangency implies exterior tangency?*

Next, we will prove that, in special circumstances, the tangency condition (1.1.3) for a function $f : \mathbb{I} \times \mathbb{K} \to \mathbb{R}$ comes from the exterior tangency condition (4.2.1) for a suitably defined extension $\tilde{f} : \mathbb{I} \times \mathbb{D} \to \mathbb{R}$ of f. More precisely, we have:

THEOREM 4.5.1. *Let $f : \mathbb{I} \times \mathbb{K} \to \mathbb{R}^n$ be a given function satisfying* (1.1.3). *If $\mathbb{V} \subseteq \mathbb{R}^n$ is a proximal neighborhood of $\mathbb{K}$ and $r : \mathbb{V} \to \mathbb{K}$ is a projection subordinated to $\mathbb{V}$, then $\tilde{f} : \mathbb{I} \times \mathbb{V} \to \mathbb{R}^n$, defined by $\tilde{f}(t,\cdot) = f(t, r(\cdot))$ satisfies* (4.2.1).

PROOF. Let $\xi \in \mathbb{V}$ and $h > 0$. We have

$$\begin{aligned}&\operatorname{dist}\big(\xi + h\tilde{f}(t,\xi);\mathbb{K}\big) - \operatorname{dist}(\xi;\mathbb{K})\\&\quad\leqslant \big\|\xi - r(\xi)\big\| + \operatorname{dist}\big(r(\xi) + hf\big(t, r(\xi)\big);\mathbb{K}\big) - \big\|\xi - r(\xi)\big\|\\&\quad= \operatorname{dist}\big(r(\xi) + hf\big(t, r(\xi)\big);\mathbb{K}\big).\end{aligned}$$

Dividing by $h > 0$ and passing to lim inf for $h \downarrow 0$, we get

$$\liminf_{h\downarrow 0}\frac{1}{h}\big[\operatorname{dist}\big(\xi + h\tilde{f}(t,\xi);\mathbb{K}\big) - \operatorname{dist}(\xi;\mathbb{K})\big] \leqslant 0.$$

So, (4.2.1) holds true with $\omega \equiv 0$, and the proof is complete. □

It should be noticed that, the conclusion of Theorem 4.5.1 is no longer true if we are looking for a continuous extension $\tilde{f}$ of a continuous function f satisfying (1.1.3), as the next example shows.

EXAMPLE 4.5.1. This example is adapted from Aubin and Cellina [3, p. 203]. Let $\mathbb{K}_1 = \{(x, 3\sqrt[3]{x^2});\ x \in \mathbb{R}_+\}$, $\mathbb{K}_2 = \{(x, 3\sqrt[3]{x^2});\ x \in \mathbb{R}_-\}$ and let $\mathbb{K} = \mathbb{K}_1 \cup \mathbb{K}_2$. If $\xi \in \mathbb{K}_1$, we define $f(\xi)$ as the unit clockwise oriented tangent vector to $\mathbb{K}_1$ at ξ, and if $\xi \in \mathbb{K}_2$, we define $f(\xi)$ as the unit counterclockwise oriented tangent vector to $\mathbb{K}_1$ at ξ. Of course, $f((0,0)) = (0,1)$. Thus $f : \mathbb{K} \to \mathbb{R}^2$ is continuous and $f(\xi) \in \mathcal{T}_{\mathbb{K}}(\xi)$ for each $\xi \in \mathbb{K}$. By virtue of Theorem 1.1.3, $\mathbb{K}$ is viable with respect to f. Let $\tilde{f}$ be any continuous extension of f to an open neighborhood $\mathbb{V}$ of the origin. We may assume that for each $v \in \mathbb{V}$, $\tilde{f}_2(v) \geqslant \frac{1}{2}$.

In fact, the equation $u'(t) = f(u(t))$ subjected to $u(0) = (0,0)$ has two local solutions $u, v : [0,\delta] \to \mathbb{K}$, with $u([0,\delta]) \subseteq \mathbb{K}_1$ and $v([0,\delta]) \subseteq \mathbb{K}_2$. Diminishing $\delta > 0$, we may assume that no solution to $u'(t) = \tilde{f}(u(t))$, $u(0) = (0,0)$, can escape from $\mathbb{V}$. Now, if we assume that $\mathbb{K}$ is invariant with respect to $\tilde{f}$, we have

$$F_{0,(0,0)}(\delta) = \big\{u(\delta);\ u'(t) = \tilde{f}\big(u(t)\big),\ \text{for all } t \in [0,\delta],\ u(0) = (0,0)\big\} \subseteq \mathbb{K},$$

and by virtue of a classical result due to Kneser—see Theorem 7.5.1—we know that $F_{0,(0,0)}(\delta)$ is connected, and therefore, we conclude that there exists at least one solution $w : [0,\delta] \to \mathbb{K}$ of $u'(t) = \tilde{f}(u(t))$, $u(0) = (0,0)$ with $w(\delta) = (0,0)$. But this is impossible, because $w_2(\delta) \geqslant \frac{1}{2}\delta$.

However, if f is continuous and $\mathbb{K}$ is smooth enough, by the very same proof we deduce:

THEOREM 4.5.2. *Let $f : \mathbb{I} \times \mathbb{K} \to \mathbb{R}^n$ be a continuous function satisfying* (1.1.3). *If there exists a proximal neighborhood $\mathbb{V} \subseteq \mathbb{R}^n$ of $\mathbb{K}$, and a continuous projection $r : \mathbb{V} \to \mathbb{K}$ subordinated to $\mathbb{V}$, then f can be extended to a continuous function $\tilde{f} : \mathbb{I} \times \mathbb{V} \to \mathbb{R}^n$ satisfying* (4.2.1).

4.6. *Local invariance and monotonicity*

We say that the preorder "$\preceq$" is *locally invariant with respect to* f if for each $(\tau,\xi)\in\mathbb{I}\times\mathbb{K}$, each solution $u:[\tau,c]\to\mathbb{D}$, $c\in(\tau,b]$, of (1.1.1) satisfying $u(\tau)=\xi$, there exists $T\in(\tau,c]$ such that $u(t)\in\mathbb{K}$ for each $t\in[\tau,T]$ and u is "$\preceq$"-monotone on $[\tau,T]$, i.e., for each $\tau\leqslant s\leqslant t\leqslant T$, we have $u(s)\preceq u(t)$. We recall that, for each $\xi\in\mathbb{K}$, $\mathcal{P}(\xi)=\{\eta\in\mathbb{K};\ \xi\preceq\eta\}$.

REMARK 4.6.1. The preorder "$\preceq$" is locally invariant with respect to f if and only if for each $(\tau,\xi)\in\mathbb{I}\times\mathbb{K}$, each solution $u:[\tau,c]\to\mathbb{D}$, $c\in(\tau,b]$, of (1.1.1) satisfying $u(\tau)=\xi$, there exists $T\in(\tau,c]$ such that, for each $s\in[\tau,T]$ and $t\in[s,T]$, we have $u(t)\in\mathcal{P}(u(s))$.

In contrast with Lemma 3.8.1, the next lemma is almost obvious.

LEMMA 4.6.1. *The preorder "$\preceq$" is locally invariant with respect to f if and only if for each $\xi\in\mathbb{K}$, $\mathcal{P}(\xi)$ is locally invariant with respect to f.*

COROLLARY 4.6.1. *If for each $\xi\in\mathbb{K}$ there exists an open neighborhood $\mathbb{V}\subseteq\mathbb{D}$ of ξ and a comparison function $\omega:\mathbb{I}\times[0,a)\to\mathbb{R}$, with $a=\sup_{\eta\in\mathbb{V}}\operatorname{dist}(\eta;\mathcal{P}(\xi))$, and such that*

$$\liminf_{h\downarrow 0}\frac{1}{h}\big[\operatorname{dist}\big(\eta+hf(t,\eta);\mathcal{P}(\xi)\big)-\operatorname{dist}\big(\eta;\mathcal{P}(\xi)\big)\big]\leqslant\omega\big(t,\operatorname{dist}\big(\eta;\mathcal{P}(\xi)\big)\big)$$

for each $(t,\eta)\in\mathbb{I}\times\mathbb{V}$, then "$\preceq$" is locally invariant with respect to f.

COROLLARY 4.6.2. *If, for each $\xi\in\mathbb{K}$, f has the comparison property with respect to $(\mathbb{D},\mathcal{P}(\xi))$ and, for each $(t,\eta)\in\mathbb{I}\times\mathcal{P}(\xi)$, we have*

$$\liminf_{h\downarrow 0}\frac{1}{h}\operatorname{dist}\big(\eta+hf(t,\eta);\mathcal{P}(\xi)\big)=0,$$

then "$\preceq$" is locally invariant with respect to f.

5. Carathéodory solutions

5.1. *A Lebesgue type derivation theorem*

In this section we extend some of the previously established results to a more general case allowing the function f to be discontinuous with respect to the time variable. This case is very important in the study of some control problems to be analyzed in the sequel, when even starting with a continuous function $(t,v,u)\mapsto f(t,v,u)$, due to the discontinuities of the optimal control $t\mapsto v^*(t)$, we have to consider a very irregular right-hand side $(t,u)\mapsto f(t,v^*(t),u)$ which is only measurable with respect to t. First we recall:

DEFINITION 5.1.1. A function $f : \mathbb{I} \times \mathbb{K} \to \mathbb{R}^n$ is *of Carathéodory type*, if it satisfies the three conditions below.

(H$_1$) For every $\xi \in \mathbb{K}$ the function $f(\cdot, \xi)$ is measurable on $\mathbb{I}$.

(H$_2$) For almost every $t \in \mathbb{I}$ the function $f(t, \cdot)$ is continuous on $\mathbb{K}$.

(H$_3$) For every $m > 0$, there exists a function $\ell_m \in L^1_{\mathrm{loc}}(\mathbb{I})$ such that $\|f(t,u)\| \leqslant \ell_m(t)$ for almost every $t \in \mathbb{I}$ and for all $u \in B(0,m) \cap \mathbb{K}$.

DEFINITION 5.1.2. A function $u : [\tau, T] \to \mathbb{K}$ is a *Carathéodory solution* to the differential equation (1.1.1) if u is absolutely continuous on $[\tau, T]$ and satisfies $u'(t) = f(t, u(t))$ a.e. for $t \in [\tau, T]$.

DEFINITION 5.1.3. We say that $\mathbb{K}$ is *Carathéodory viable* with respect to $f : \mathbb{I} \times \mathbb{K} \to \mathbb{R}^n$ if for each $(\tau, \xi) \in \mathbb{I} \times \mathbb{K}$ there exist $T \in \mathbb{I}$, $T > \tau$ and a Carathéodory solution $u : [\tau, T] \to \mathbb{K}$ to (1.1.1), satisfying $u(\tau) = \xi$.

Clearly, if $\mathbb{K}$ is viable with respect to f, then it is Carathéodory viable, but not conversely. In order to prove some necessary and sufficient conditions for Carathédory viability, we recall first a Lebesgue type derivation theorem due to Scorza Dragoni [88]. For more general results see Frankowska et al. [45] and Cârjă and Monteiro Marques [21].

THEOREM 5.1.1. *Assume* (H$_1$), (H$_2$) *and* (H$_3$). *Then there exists a negligible subset* $\mathbb{Z}$ *of* $\mathbb{I}$ *such that, for every* $t \in \mathbb{I} \setminus \mathbb{Z}$ *and every* $\xi \in \mathbb{K}$, *one has*

$$\lim_{h \downarrow 0} \frac{1}{h} \int_t^{t+h} f\big(s, u(s)\big)\,\mathrm{d}s = f(t, \xi) \tag{5.1.1}$$

for all continuous functions $u : \mathbb{I} \to \mathbb{K}$ *with* $u(t) = \xi$.

In order to prove Theorem 5.1.1, we recall for easy reference a specific form of a Lusin type continuity result due to Scorza Dragoni [87]. For more general results see Berliocchi and Lasry [10] and Kucia [63].

Here and thereafter, λ denotes the usual Lebesgue measure on $\mathbb{R}$.

THEOREM 5.1.2 (Scorza Dragoni [87]). *Let* $f : \mathbb{I} \times \mathbb{K} \to \mathbb{R}^n$ *be a function that satisfies* (H$_1$) *and* (H$_2$). *Then, for each* $\varepsilon > 0$, *there exists a closed set* $\mathbb{A} \subseteq \mathbb{I}$ *such that* $\lambda(\mathbb{I} \setminus \mathbb{A}) < \varepsilon$ *and the restriction of* f *to* $\mathbb{A} \times \mathbb{K}$ *is continuous.*

We note that the conclusion of Theorem 5.1.2 holds also true if $\mathbb{I}$ is replaced by any Lebesgue measurable subset in $\mathbb{R}$, while $\mathbb{K}$ and $\mathbb{R}^n$ are replaced by two separable metric spaces X and respectively Y. We can now proceed to the proof of Theorem 5.1.1.

PROOF OF THEOREM 5.1.1. Since $\mathbb{I}$ is a countable union of finite length intervals, it suffices to consider the case when $\mathbb{I}$ is of finite length. For each $\gamma > 0$, we shall obtain a set $\mathbb{L}_\gamma \subset \mathbb{I}$, with $\lambda(\mathbb{I} \setminus \mathbb{L}_\gamma) < \gamma$, and such that (5.1.1) holds for all $t \in \mathbb{L}_\gamma$. Finally, since $\lambda(\mathbb{I} \setminus \mathbb{L}_\gamma) < \gamma$, it will suffice to consider $\mathbb{Z} = \cap_m (\mathbb{I} \setminus \mathbb{L}_{1/m})$.

Let $\gamma > 0$ and let us observe that, by virtue of Theorem 5.1.2, it follows that there exists a compact set $\mathbb{A}_\gamma \subseteq \mathbb{I}$ such that $\lambda(\mathbb{I} \setminus \mathbb{A}_\gamma) < \gamma$, and the restriction of f to $\mathbb{A}_\gamma \times \mathbb{K}$ is continuous.

We define $\mathbb{L}_\gamma \subseteq \mathbb{A}_\gamma$ as the set of density points of $\mathbb{A}_\gamma$ which are also Lebesgue points of the functions $\tilde{\ell}_m : \mathbb{I} \to \mathbb{R}$, given by $\tilde{\ell}_m(t) = \ell_m(t)\chi_{\mathbb{I}\setminus\mathbb{A}_\gamma}(t)$, where ℓ_m is given by (H3), $m = 1, 2, \ldots$. It is known that $\lambda(\mathbb{L}_\gamma) = \lambda(\mathbb{A}_\gamma)$ and, by definition, for $t \in \mathbb{L}_\gamma$ we have

$$\begin{aligned} &\lim_{t\in\mathbb{J};\lambda(\mathbb{J})\to 0} \frac{\lambda(\mathbb{A}_\gamma \cap \mathbb{J})}{\lambda(\mathbb{J})} = 1, \\ &\lim_{t\in\mathbb{J};\lambda(\mathbb{J})\to 0} \frac{1}{\lambda(\mathbb{J})} \int_{\mathbb{J}} \left|\tilde{\ell}_m(s) - \tilde{\ell}_m(t)\right| \mathrm{d}s = 0, \end{aligned} \tag{5.1.2}$$

where $\mathbb{J}$ denotes intervals of positive length.

Let $t \in \mathbb{L}_\gamma$. Consider a continuous function $u : \mathbb{I} \to \mathbb{K}$, and denote by $\xi = u(t)$. Then, there is $m \geqslant 1$ such that $\|u(\theta)\| < m$ for all $\theta \in [t, t+\delta]$, where $\delta > 0$ is sufficiently small. Let $\varepsilon > 0$ be arbitrary. We can further assume that, for all $\theta \in \mathbb{A}_\gamma \cap [t, t+\delta]$,

$$\left\| f\big(\theta, u(\theta)\big) - f(t, \xi)\right\| \leqslant \frac{\varepsilon}{3}. \tag{5.1.3}$$

By taking a smaller δ if necessary, in view of (5.1.2), we can also ensure that

$$\frac{1}{s}\int_{[t,t+s]\setminus\mathbb{A}_\gamma} \ell_m(\theta)\,\mathrm{d}\theta \leqslant \frac{\varepsilon}{3}, \tag{5.1.4}$$

for every $s \in (0, \delta)$, and also

$$\frac{\lambda([t, t+s] \setminus \mathbb{A}_\gamma)}{s} \left\| f(t, \xi)\right\| \leqslant \frac{\varepsilon}{3} \tag{5.1.5}$$

for every $s \in (0, \delta)$. Then, by (5.1.3), for $s \in (0, \delta)$, we have

$$\frac{1}{s}\int_{[t,t+s]\cap\mathbb{A}_\gamma} \left\| f\big(\theta, u(\theta)\big) - f(t, \xi)\right\| \mathrm{d}\theta \leqslant \frac{\varepsilon}{3}\frac{\lambda([t, t+s] \cap \mathbb{A}_\gamma)}{s} \leqslant \frac{\varepsilon}{3},$$

while by (5.1.4) and (5.1.5) we have

$$\begin{aligned} &\frac{1}{s}\int_{[t,t+s]\setminus\mathbb{A}_\gamma} \left\| f\big(\theta, u(\theta)\big) - f(t, \xi)\right\| \mathrm{d}\theta \\ &\quad\leqslant \frac{1}{s}\int_{[t,t+s]\setminus\mathbb{A}_\gamma} \big(\ell_m(\theta) + \left\| f(t, \xi)\right\|\big)\,\mathrm{d}\theta \\ &\quad\leqslant \frac{1}{s}\int_{[t,t+s]\setminus\mathbb{A}_\gamma} \ell_m(\theta)\,\mathrm{d}\theta + \frac{\lambda([t, t+s] \setminus \mathbb{A}_\gamma)}{s}\left\| f(t, \xi)\right\| \leqslant 2\frac{\varepsilon}{3}. \end{aligned}$$

Finally, we have

$$\left\| \frac{1}{s} \int_t^{t+s} f\big(\theta, u(\theta)\big)\, \mathrm{d}\theta - f(t,\xi) \right\| \leqslant \varepsilon,$$

for all $s \in (0, \delta)$ and this completes the proof. □

Using similar arguments we can prove:

THEOREM 5.1.3. *Assume* (H$_1$), (H$_2$) *and* (H$_3$). *Then there exists a negligible subset* $\mathbb{Z}$ *of* $\mathbb{I}$ *such that*, *for every* $t \in \mathbb{I} \setminus \mathbb{Z}$ *and every* $\xi \in \mathbb{K}$, *one has*

$$\lim_{h \downarrow 0} \frac{1}{h} \int_t^{t+h} f\big(s, v(h)\big)\, \mathrm{d}s = f(t,\xi)$$

for all functions $v : [0, +\infty) \to \mathbb{K}$ *satisfying* $\lim_{h\downarrow 0} v(h) = \xi$.

PROOF. The proof proceeds similarly with that one of Theorem 5.1.1 up to and including the sentence: "Let $t \in \mathbb{L}_\gamma$." We continue as follows. There is $m \geqslant 1$ such that $\|v(h)\| < m$ for $h \in (0, \delta)$ where $\delta > 0$ is sufficiently small. Let $\varepsilon > 0$ be arbitrary. We can assume that, for all $\theta \in \mathbb{A}_\gamma \cap [t, t+\delta]$ and $h \in (0, \delta)$,

$$\big\| f\big(\theta, v(h)\big) - f(t,\xi) \big\| \leqslant \frac{\varepsilon}{3}.$$

By taking a smaller δ if necessary, in view of (5.1.2), we can also ensure that (5.1.4) and (5.1.5) hold. From now on, the proof follows the very same way as that one of Theorem 5.1.1, with the observation that, here, $f(\theta, u(\theta))$ should be replaced by $f(\theta, v(h))$, wherever it appears. □

5.2. *Characterizations of Carathéodory viability*

We are now ready to prove the main characterizations of Carathéodory viability.

THEOREM 5.2.1. *Suppose that* $\mathbb{K}$ *is locally closed and* $f : \mathbb{I} \times \mathbb{K} \to \mathbb{R}^n$ *is of Carathéodory type. Then the following conditions are equivalent*:

(i) *there exists a negligible set* $\mathbb{Z} \subset \mathbb{I}$ *such that for every* $t \in \mathbb{I} \setminus \mathbb{Z}$ *and for every* $\xi \in \mathbb{K}$, $f(t,\xi) \in \mathcal{C}_{\mathbb{K}}(\xi)$,

(ii) *there exists a negligible set* $\mathbb{Z} \subset \mathbb{I}$ *such that for every* $t \in \mathbb{I} \setminus \mathbb{Z}$ *and for every* $\xi \in \mathbb{K}$, $f(t,\xi) \in \mathcal{T}_{\mathbb{K}}(\xi)$,

(iii) *there exists a negligible set* $\mathbb{Z} \subseteq \mathbb{I}$ *such that for every* $t \in \mathbb{I} \setminus \mathbb{Z}$ *and for every* $\xi \in \mathbb{K}$, $f(t,\xi) \in \mathcal{B}_{\mathbb{K}}(\xi)$,

(iv) *for each* $\xi \in \mathbb{K}$ *there exists a negligible set* $\mathbb{Z}_\xi \subseteq \mathbb{I}$ *such that for every* $t \in \mathbb{I} \setminus \mathbb{Z}_\xi$, $f(t,\xi) \in \mathcal{C}_{\mathbb{K}}(\xi)$,

(v) *for each* $\xi \in \mathbb{K}$ *there exists a negligible set* $\mathbb{Z}_\xi \subseteq \mathbb{I}$ *such that for every* $t \in \mathbb{I} \setminus \mathbb{Z}_\xi$, $f(t,\xi) \in \mathcal{T}_{\mathbb{K}}(\xi)$,

(vi) *for each* $\xi \in \mathbb{K}$ *there exists a negligible set* $\mathbb{Z}_\xi \subseteq \mathbb{I}$ *such that for every* $t \in \mathbb{I} \setminus \mathbb{Z}_\xi$, $f(t,\xi) \in \mathcal{B}_{\mathbb{K}}(\xi)$,

(vii) $\mathbb{K}$ *is Carathéodory viable with respect to* f.

In general, if $\mathcal{G} : \mathbb{K} \rightsquigarrow \mathbb{R}^n$ *is such that* $\mathcal{C}_{\mathbb{K}}(\xi) \subseteq \mathcal{G}(\xi) \subseteq \mathcal{B}_{\mathbb{K}}(\xi)$ *for each* $\xi \in \mathbb{K}$, *then each one of the conditions below*:

(viii) *there exists a negligible set* $\mathbb{Z} \subseteq \mathbb{I}$ *such that for every* $t \in \mathbb{I} \setminus \mathbb{Z}$ *and for every* $\xi \in \mathbb{K}$, $f(t,\xi) \in \mathcal{G}(\xi)$,

(ix) *for each* $\xi \in \mathbb{K}$ *there exists a negligible set* $\mathbb{Z}_\xi \subseteq \mathbb{I}$ *such that for every* $t \in \mathbb{I} \setminus \mathbb{Z}_\xi$, $f(t,\xi) \in \mathcal{G}(\xi)$,

is equivalent to each one of the seven conditions above.

In order to prove Theorem 5.2.1, we need two auxiliary lemmas.

LEMMA 5.2.1. *Let* $\mathbb{K} \subseteq \mathbb{R}^n$ *be locally closed, let* $f : \mathbb{I} \times \mathbb{K} \to \mathbb{R}^n$ *be a function of Carathéodory type, let* $[\tau, T] \subseteq \mathbb{I}$, $\xi \in \mathbb{K}$, *and let* $\rho > 0$ *be such that* $\mathbb{K} \cap B(\xi,\rho)$ *is closed and there exists* $\ell \in L^1(\tau,T)$ *such that* $\|f(s,\eta)\| \leqslant \ell(s)$ *a.e. for* $s \in [\tau,T]$ *and for all* $\eta \in \mathbb{K} \cap B(\xi,\rho)$. *Then the family*

$$\mathcal{F} = \left\{ f(\cdot,\eta);\ \eta \in \mathbb{K} \cap B(\xi,\rho) \right\}$$

is compact in $L^1(\tau,T;\mathbb{R}^n)$.

PROOF. Let $(f(\cdot,\eta_m))_m$ be a sequence in $\mathcal{F}$. Since for all $m \in \mathbb{N}$, we have $\eta_m \in \mathbb{K} \cap B(\xi,\rho)$ and the latter is compact, there exist a subsequence of $(\eta_m)_m$, denoted for simplicity again by $(\eta_m)_m$, and $\eta \in \mathbb{K} \cap B(\xi,\rho)$, such that $\lim_m \eta_m = \eta$. It readily follows that $\lim_m f(s,\eta_m) = f(s,\eta)$ a.e. for $s \in [\tau,T]$. Since $\|f(s,\eta_m)\| \leqslant \ell(s)$ a.e. for $s \in [\tau,T]$ and for all $m \in \mathbb{N}$, by virtue of Lebesgue dominated convergence theorem, we deduce that

$$\lim_m \int_\tau^T \left\| f(s,\eta_m) - f(s,\eta) \right\| \mathrm{d}s = 0,$$

and this achieves the proof. □

LEMMA 5.2.2. *Let* $\mathbb{K} \subseteq \mathbb{R}^n$ *be locally closed, let* $f : \mathbb{I} \times \mathbb{K} \to \mathbb{R}^n$ *be a function of Carathéodory type, let* $[\tau, T] \subseteq \mathbb{I}$ *with* $T < \sup \mathbb{I}$, *let* $h > 0$ *with* $T + h < \sup \mathbb{I}$ *and let* $f_h : [\tau,T] \times \mathbb{K} \to \mathbb{R}^n$ *be defined by*

$$f_h(t,\xi) = \frac{1}{h} \int_t^{t+h} f(s,\xi)\,\mathrm{d}s$$

for each $(t,\xi) \in [\tau,T] \times \mathbb{K}$. *Then* f_h *is continuous on* $[\tau,T] \times \mathbb{K}$.

PROOF. Let $(t,\xi) \in [\tau,T] \times \mathbb{K}$. Since $\mathbb{K}$ is locally closed and f satisfies (H_3), there exist $\rho > 0$ and $\ell \in L^1(\tau,T)$ such that $K \cap B(\xi,\rho)$ is closed and $\|f(s,\eta)\| \leqslant \ell(s)$ a.e. for

$s \in [\tau, T]$ and for all $\eta \in K \cap B(\xi, \rho)$. Then, for each θ with $[t+\theta, t+h+\theta] \subset \mathbb{I}$, and each $\eta \in K \cap B(\xi, \rho)$, we have

$$\begin{aligned}
&\big\| f_h(t+\theta, \eta) - f_h(t, \xi) \big\| \\
&\quad = \left\| \frac{1}{h} \int_{t+\theta}^{t+\theta+h} f(s, \eta)\, \mathrm{d}s - \frac{1}{h} \int_{t}^{t+h} f(s, \xi)\, \mathrm{d}s \right\| \\
&\quad \leqslant \frac{1}{h} \int_{t}^{t+h} \big\| f(s+\theta, \eta) - f(s, \eta) \big\|\, \mathrm{d}s + \frac{1}{h} \int_{t}^{t+h} \big\| f(s, \eta) - f(s, \xi) \big\|\, \mathrm{d}s.
\end{aligned}$$

In view of Lemma 5.2.1 and Theorem A.1.1, we have

$$\lim_{\theta \to 0} \int_{t}^{t+h} \big\| f(s+\theta, \eta) - f(s, \eta) \big\|\, \mathrm{d}s = 0$$

uniformly for $\eta \in \mathbb{K} \cap B(\xi, \rho)$. Next, using condition (H_2) in Definition 5.1.1, the fact that $\| f(s, \eta) \| \leqslant \ell(s)$ a.e. for $s \in [t, t+h]$ and for all $\eta \in \mathbb{K} \cap B(\xi, \rho)$, by virtue of Lebesgue dominated convergence theorem, we deduce that

$$\lim_{\eta \to \xi} \int_{t}^{t+h} \big\| f(s, \eta) - f(s, \xi) \big\|\, \mathrm{d}s = 0,$$

relation which, along with the preceding one, shows that

$$\lim_{(\theta, \eta) \to (0, \xi)} \big\| f_h(t+\theta, \eta) - f_h(t, \xi) \big\| = 0,$$

and this completes the proof. □

We can now proceed to the proof of Theorem 5.2.1.

PROOF OF THEOREM 5.2.1. In view of Theorem 3.4.1, (i) (ii) and (iii) are equivalent. Furthermore (i) implies (iv), (iv) implies (v) and (v) implies (vi). In order to show that the first seven conditions are equivalent, it remains to prove that (vi) implies (vii) and (vii) implies (ii). Let us prove that (vi) implies (vii). To this aim, let $\mathbb{V}$ be an open neighborhood of $\mathbb{K}$ such that $\Pi_{\mathbb{K}}(\xi) \neq \emptyset$ for each $\xi \in \mathbb{V}$. The existence of the set $\mathbb{V}$, enjoying the specified properties, is ensured by Lemma 2.2.1. Let $\ell \in L^1_{\mathrm{loc}}(\mathbb{I})$ and let $(\tau, \xi) \in \mathbb{I} \times \mathbb{K}$ be arbitrary. We claim that we can choose $\rho > 0$ and $T \in \mathbb{I}$ with $\tau < T < \sup \mathbb{I}$, such that $B(\xi, \rho) \cap \mathbb{K}$ is closed, $B(\xi, \rho) \subseteq \mathbb{V}$,

$$\big\| f(t, u) \big\| \leqslant \ell(t) \tag{5.2.1}$$

a.e. for $t \in [\tau, T]$ and for each $u \in B(\xi, \rho)$, and

$$\int_{\tau}^{T} \ell(s)\, \mathrm{d}s \leqslant \frac{\rho}{2}. \tag{5.2.2}$$

Indeed, since $\mathbb{V}$ is open and $\mathbb{K}$ is locally closed, we can get a $\rho > 0$ with $B(\xi,\rho)\cap\mathbb{K}$ closed and $B(\xi,\rho)\subseteq\mathbb{V}$. Further, as f satisfies (H$_3$), it follows that there exists $\ell\in L^1_{\mathrm{loc}}(\mathbb{I})$ satisfying (5.2.1). Finally, diminishing T if necessary, we get (5.2.2) and $T<\sup\mathbb{I}$. Next, let $h>0$ with $T+h<\sup\mathbb{I}$, and let us define $f_h:[\tau,T]\to\mathbb{R}^n$ by

$$f_h(t,\xi)=\frac{1}{h}\int_t^{t+h} f(s,\xi)\,\mathrm{d}s.$$

From Lemma 5.2.2, we know that f_h is continuous. On the other hand, since (vi) holds, we have $\langle f_h(t,\xi),\zeta\rangle\leqslant 0$, for all $t\in\mathbb{I}$ and $\zeta\in\mathcal{N}_{\mathbb{K}}(\xi)$, and thus the function f_h satisfies the condition (v) in Theorem 3.4.1 with $\mathcal{G}=\overline{\mathrm{co}}\,\mathcal{T}_{\mathbb{K}}(\xi)$. Therefore, for each $h>0$, with $T+h<\sup\mathbb{I}$, $\mathbb{K}$ is viable with respect to f_h. This implies that, for any $h>0$, $T+h<\sup\mathbb{I}$, there exists $T_h\in(\tau,T]$ and a solution $u_h:[\tau,T_h]\to\mathbb{K}$ of the differential equation $u'(t)=f_h(t,u(t))$ with $u_h(\tau)=\xi$. From Theorem 3.5.1, using (5.2.1) and (5.2.2), we conclude that we may choose $T_h=T$ for each $h>0$, $T+h<\sup\mathbb{I}$. Therefore, for each sufficiently small $h>0$, $u'(t)=f_h(t,u(t))$ has at least one solution $u_h:[\tau,T]\to B(\xi,\rho)\cap\mathbb{K}$ satisfying $u_h(\tau)=\xi$.

Take $h_m\downarrow 0$, and let $u_m=u_{h_m}$ be a solution to $u'(t)=f_m(t,u(t))$ with $f_m=f_{h_m}$ on $[\tau,T]$ and $u_m(\tau)=\xi$. We will prove that, for a certain function $u:[\tau,T]\to\mathbb{K}$, $\lim_m u_m(t)=u(t)$ uniformly for $t\in[\tau,T]$, and u is a Carathéodory solution to (1.1.1) satisfying $u(\tau)=\xi$. In order to do this, we will show first that $\{u_m;\ m\in\mathbb{N}\}$ satisfies the hypotheses of Arzelà–Ascoli theorem. Let $\mathbb{E}\subset[\tau,T]$ be a Lebesgue measurable set and let us observe that

$$\begin{aligned}
&\int_{\mathbb{E}}\left\|u_m'(t)\right\|\mathrm{d}t\\
&\quad=\int_{\mathbb{E}}\left\|f_{h_m}\big(t,u_m(t)\big)\right\|\mathrm{d}t=\int_{\mathbb{E}}\left\|\frac{1}{h_m}\int_t^{t+h_m} f\big(s,u_m(t)\big)\,\mathrm{d}s\right\|\mathrm{d}t\\
&\quad=\int_{\mathbb{E}}\left\|\frac{1}{h_m}\int_0^{h_m} f\big(t+s,u_m(t)\big)\,\mathrm{d}s\right\|\mathrm{d}t\\
&\quad\leqslant\frac{1}{h_m}\int_0^{h_m}\int_{\mathbb{E}}\left\|f\big(t+s,u_m(t)\big)\right\|\mathrm{d}t\,\mathrm{d}s\leqslant\frac{1}{h_m}\int_0^{h_m}\int_{\mathbb{E}}\ell(t+s)\,\mathrm{d}t\,\mathrm{d}s.
\end{aligned}$$

Since $\ell\in L^1_{\mathrm{loc}}(\mathbb{I})$, for each $\varepsilon>0$ there exists $\delta(\varepsilon)>0$ such that, for each $\mathbb{E}\subset[\tau,T+h_1]$ with $\lambda(\mathbb{E})\leqslant\delta(\varepsilon)$, we have

$$\int_{\mathbb{E}}\ell(t)\,\mathrm{d}t\leqslant\varepsilon.$$

Since the Lebesgue measure is translation invariant, it follows that, for each $\mathbb{E}\subseteq[\tau,T]$ with $\lambda(\mathbb{E})\leqslant\delta(\varepsilon)$, we have

$$\int_{\mathbb{E}}\ell(t+s)\,\mathrm{d}t\leqslant\varepsilon$$

for each $s \in [0, h_1]$. Summing up, we conclude that

$$\int_{\mathbb{E}} \|u_m'(t)\| \,\mathrm{d}t \leqslant \frac{1}{h_m} \int_0^{h_m} \int_{\mathbb{E}} \ell(t+s) \,\mathrm{d}t \,\mathrm{d}s \leqslant \varepsilon$$

for each $\mathbb{E} \subseteq [\tau, T]$ with $\lambda(\mathbb{E}) \leqslant \delta(\varepsilon)$. So $\{u_m';\ m \in \mathbb{N}\}$ is uniformly integrable. This implies that $\{u_m;\ m \in \mathbb{N}\}$ is equicontinuous. Moreover, since $u_m(t) \in \mathbb{K} \cap B(\xi, \rho)$ for each $t \in [\tau, T]$, if readily follows that $\{u_m;\ m \in \mathbb{N}\}$ is uniformly bounded. Therefore, there exists $u : [\tau, T] \to \mathbb{K} \cap B(\xi, \rho)$ such that, at least on a subsequence, denoted for simplicity again by $(u_m)_m$, we have $\lim_m u_m(t) = u(t)$ uniformly for $t \in [\tau, T]$. Clearly u is continuous. On the other hand, by Theorem 5.1.3, we have

$$\lim_{m\to\infty} \frac{1}{h_m} \int_s^{s+h_m} f\big(\theta, u_m(s)\big) \,\mathrm{d}\theta = f\big(s, u(s)\big)$$

a.e. for $s \in [\tau, T]$. Since $\{u_m';\ m \in \mathbb{N}\}$ is uniformly integrable, by virtue of Vitali's Theorem A.1.2, we conclude that

$$\begin{aligned}\lim_{m\to\infty} u_m(t) &= \lim_{m\to\infty} \left(\xi + \int_\tau^t \frac{1}{h_m} \int_s^{s+h_m} f\big(\theta, u_m(s)\big) \,\mathrm{d}\theta \,\mathrm{d}s \right) \\ &= \xi + \int_\tau^t f\big(s, u(s)\big) \,\mathrm{d}s,\end{aligned}$$

which shows that u is a Carathéodory solution to (1.1.1) satisfying $u(\tau) = \xi$. Hence $\mathbb{K}$ is Carathéodory viable with respect to f, and this shows that (vi) implies (vii).

Next, to prove that (vii) implies (ii), let $\mathbb{Z} \subset \mathbb{I}$ be a negligible set as in Theorem 5.1.1. Let $t \in \mathbb{I} \setminus \mathbb{Z}$, $\xi \in \mathbb{K}$ and let $u(\cdot)$ be a Carathéodory solution to $u'(s) = f(s, u(s))$ on $[t, t+T]$ with $u(t) = \xi$ and $u(s) \in \mathbb{K}$ for $s \in [t, t+h]$. We have

$$\frac{u(t+h) - u(t)}{h} = \frac{1}{h} \int_t^{t+h} f\big(s, u(s)\big) \,\mathrm{d}s.$$

On the other hand, by (5.1.1), the right-hand side approaches $f(t, \xi)$ as $h \downarrow 0$. Accordingly

$$\lim_{h\downarrow 0} \frac{1}{h} \operatorname{dist}\big(\xi + hf(t, \xi); \mathbb{K}\big) \leqslant \lim_{h\downarrow 0} \left\| f(t, \xi) - \frac{u(t+h) - u(t)}{h} \right\| = 0$$

and so, $f(t, \xi) \in \mathcal{F}_{\mathbb{K}}(\xi) \subseteq \mathcal{T}_{\mathbb{K}}(\xi)$, which shows that (ii) holds.

Now, (viii) implies (iii) which implies (vii), and (vii) implies (i) which implies (viii). Finally, (ix) implies (vi) which implies (vii), and (vii) implies (iv) which implies (ix). The proof is complete. □

5.3. *Sufficient conditions for Carathéodory local invariance*

The aim of this section is to extend the results concerning local invariance to the more general setting allowing the function f to be of Carathéodory type. Unlike the case of necessary and sufficient conditions for Carathéodory viability whose proofs differ essentially from those referring to viability, all the results which will follow are simple copies of their "C^1-solutions" counterparts we already presented when we dealt with local invariance. Therefore, we do not enter into details.

Let $\mathbb{D}$ be a domain in $\mathbb{R}^n$, $\mathbb{K} \subseteq \mathbb{D}$ a locally closed subset, and let us consider the ordinary differential equation (1.1.1), where $f : \mathbb{I} \times \mathbb{D} \to \mathbb{R}^n$ is a given function.

DEFINITION 5.3.1. The subset $\mathbb{K}$ is *Carathéodory locally invariant* with respect to f if for each $(\tau, \xi) \in \mathbb{I} \times \mathbb{K}$ and each Carathéodory solution $u : [\tau, c] \to \mathbb{D}$, $c \in \mathbb{I}$, $c > \tau$, to (1.1.1), satisfying the initial condition $u(\tau) = \xi$, there exists $T \in (\tau, c]$ such that we have $u(t) \in \mathbb{K}$ for each $t \in [\tau, T]$. It is *Carathéodory invariant* if it satisfies the above condition of Carathéodory local invariance with $T = c$.

REMARK 5.3.1. If $\mathbb{K}$ is Carathéodory locally invariant with respect to f, then $\mathbb{K}$ is locally invariant with respect to f. We notice that here we do have any extra-condition upon f as of being of Carathéodory type. It should be interesting to know if, under the latter assumption on f, the local invariance implies the Carathéodory local invariance.

The relationship between Carathéodory viability and Carathéodory local invariance is clarified in:

REMARK 5.3.2. If f is of Carathéodory type on $\mathbb{I} \times \mathbb{D}$ and $\mathbb{K}$ is Carathéodory locally invariant with respect to f, then $\mathbb{K}$ is Carathéodory viable with respect to f. The converse of this assertion is no longer true, as we already have seen in Example 4.1.1.

As in the case of local invariance, we have the following simple necessary and sufficient condition of Carathéodory local invariance.

THEOREM 5.3.1. *Let $\mathbb{D}$ be a domain, $\mathbb{K} \subseteq \mathbb{D}$ a nonempty and locally closed subset and $f : \mathbb{I} \times \mathbb{D} \to \mathbb{R}^n$ a Carathéodory type function with the property that* (1.1.1) *has the uniqueness property. Then, a necessary and sufficient condition in order that $\mathbb{K}$ be invariant with respect to f is each one of the nine conditions* (i)–(ix) *in Theorem* 5.2.1.

PROOF. The conclusion follows from the Carathéodory Local Existence Theorem combined with Remark 5.3.2 and the equivalence between (i) and (ix) in Theorem 5.2.1. □

As in the case of local invariance, the Carathéodory local invariance of $\mathbb{K}$ with respect to f can take place even if $u'(t) = f_{|\mathbb{I}\times\mathbb{K}}(t, u(t))$ has not the uniqueness property. See Example 4.1.2.

We say that $\omega : \mathbb{I} \times [0, \rho) \to \mathbb{R}$ is a *Carathéodory comparison function* if, for each $[\tau, T) \subseteq \mathbb{I}$, the only absolutely continuous solution $x : [\tau, T) \to [0, \rho)$, of $[D_+x](t) \leqslant \omega(t, x(t))$ a.e. for $t \in [\tau, T)$, satisfying $x(\tau) = 0$, is the null function.

Our first sufficient condition for Carathéodory local invariance is expressed by means of the "exterior tangency" condition: there exist a negligible subset $\mathbb{Z}$ in $\mathbb{I}$ and an open neighborhood $\mathbb{V} \subseteq \mathbb{D}$ of $\mathbb{K}$ such that

$$\liminf_{h \downarrow 0} \frac{1}{h}\bigl[\operatorname{dist}\bigl(\xi + hf(t,\xi); \mathbb{K}\bigr) - \operatorname{dist}(\xi; \mathbb{K})\bigr] \leqslant \omega\bigl(t, \operatorname{dist}(\xi; \mathbb{K})\bigr) \tag{5.3.1}$$

for each $(t, \xi) \in (\mathbb{I} \setminus \mathbb{Z}) \times \mathbb{V}$, where ω is a certain Carathéodory comparison function.

The next result is a "Carathéodory" counterpart of Theorem 4.2.1.

THEOREM 5.3.2. *Let $\mathbb{K} \subseteq \mathbb{D} \subseteq \mathbb{R}^n$, with $\mathbb{K}$ locally closed and $\mathbb{D}$ open, and let $f : \mathbb{I} \times \mathbb{D} \to \mathbb{R}^n$. If* (5.3.1) *is satisfied, then $\mathbb{K}$ is Carathéodory locally invariant with respect to f.*

Theorem 5.3.2 can be reformulated as:

THEOREM 5.3.3. *Let $\mathbb{K} \subseteq \mathbb{D} \subseteq \mathbb{R}^n$, with $\mathbb{K}$ locally closed and $\mathbb{D}$ open, and let $f : \mathbb{I} \times \mathbb{D} \to \mathbb{R}^n$. If there exists an open neighborhood V of $\mathbb{K}$ with $\mathbb{V} \subseteq \mathbb{D}$ such that ω_f defined by* (4.2.2) *is a Carathéodory comparison function, then $\mathbb{K}$ is Carathéodory locally invariant with respect to f.*

DEFINITION 5.3.2. Let $\mathbb{K} \subseteq \mathbb{D} \subseteq \mathbb{R}^n$. We say that a function $f : \mathbb{I} \times \mathbb{D} \to \mathbb{R}^n$ has the *Carathéodory comparison property with respect to* $(\mathbb{D}, \mathbb{K})$ if there exist a negligible subset $\mathbb{Z}$ of $\mathbb{I}$, a proximal neighborhood $\mathbb{V} \subseteq \mathbb{D}$ of $\mathbb{K}$, one projection $\pi_{\mathbb{K}} : \mathbb{V} \to \mathbb{K}$ subordinated to $\mathbb{V}$, and a Carathéodory comparison function $\omega : \mathbb{I} \times [0, a) \to \mathbb{R}$, with $a = \sup_{\xi \in \mathbb{V}} \operatorname{dist}(\xi; \mathbb{K})$, such that

$$\bigl[\xi - \pi_{\mathbb{K}}(\xi), f(t,\xi) - f\bigl(t, \pi_{\mathbb{K}}(\xi)\bigr)\bigr]_+ \leqslant \omega\bigl(t, \bigl\|\xi - \pi_{\mathbb{K}}(\xi)\bigr\|\bigr)$$

for each $(t, \xi) \in (\mathbb{I} \setminus \mathbb{Z}) \times \mathbb{V}$.

THEOREM 5.3.4. *Let $\mathbb{K} \subseteq \mathbb{D} \subseteq \mathbb{R}^n$, with $\mathbb{K}$ locally closed and $\mathbb{D}$ open, and let $f : \mathbb{I} \times \mathbb{D} \to \mathbb{R}^n$. If f has the Carathéodory comparison property with respect to* $(\mathbb{D}, \mathbb{K})$, *and $\mathbb{K}$ is Carathéodory viable with respect f, then* (5.3.1) *holds true.*

Other sufficient conditions for invariance obtained from Theorem 5.2.1 are:

THEOREM 5.3.5. *Let $\mathbb{K} \subseteq \mathbb{D} \subseteq \mathbb{R}^n$, with $\mathbb{K}$ locally closed and $\mathbb{D}$ open, and let $f : \mathbb{I} \times \mathbb{D} \to \mathbb{R}^n$ be of Carathéodory type. Let us assume that f has the Carathéodory comparison property with respect to* $(\mathbb{D}, \mathbb{K})$, *and satisfies one of the nine equivalent tangency conditions* (i)–(ix) *in Theorem* 5.2.1. *Then $\mathbb{K}$ is Carathéodory locally invariant with respect to f.*

5.4. *Sufficient conditions via generalized distance*

Here we reconsider the sufficient conditions for local invariance obtained by means of a proximal generalized distance in the context of Carathéodory type functions.

THEOREM 5.4.1. *Let $\mathbb{K} \subseteq \mathbb{D} \subseteq \mathbb{R}^n$, and let $f : \mathbb{I} \times \mathbb{D} \to \mathbb{R}^n$. If there exist an open neighborhood $\mathbb{V}$ of $\mathbb{K}$, with $\mathbb{V} \subseteq \mathbb{D}$, a proximal generalized distance $g : \mathbb{V} \to \mathbb{R}_+$, a negligible subset $\mathbb{Z}$ in $\mathbb{I}$ and a Carathéodory comparison function $\omega : \mathbb{I} \times [0, a) \to \mathbb{R}$ such that*

$$\liminf_{h \downarrow 0} \frac{1}{h}\bigl[g\bigl(\xi + hf(t,\xi)\bigr) - g(\xi)\bigr] \leqslant \omega\bigl(t, g(\xi)\bigr)$$

for each $(t, \xi) \in (\mathbb{I} \setminus \mathbb{Z}) \times \mathbb{V}$, then $\mathbb{K}$ is Carathéodory locally invariant with respect to f.

Let $g : \mathbb{V} \to [0, +\infty)$ be a proximal generalized distance, and let us introduce the generalized Carathéodory tangency condition: *there exists a negligible subset $\mathbb{Z}$ of $\mathbb{I}$ such that*

$$\liminf_{h \downarrow 0} \frac{1}{h} g\bigl(\xi + hf(t,\xi)\bigr) = 0 \tag{5.4.1}$$

for each $(t, \xi) \in (\mathbb{I} \setminus \mathbb{Z}) \times \mathbb{K}$.

THEOREM 5.4.2. *Let $\mathbb{K} \subseteq \mathbb{D} \subseteq \mathbb{R}^n$, and let $f : \mathbb{I} \times \mathbb{D} \to \mathbb{R}^n$. If there exist an open neighborhood $\mathbb{V}$ of $\mathbb{K}$, with $\mathbb{V} \subseteq \mathbb{D}$, a proximal generalized distance $g : \mathbb{V} \to \mathbb{R}_+$, a negligible subset $\mathbb{Z}$ in $\mathbb{I}$ and a Carathéodory comparison function $\omega : \mathbb{I} \times [0, a) \to \mathbb{R}$ satisfying* (5.4.1) *and such that*

$$\liminf_{h \downarrow 0} \frac{1}{2h}\bigl[g^2\bigl(\xi + hf(t,\xi)\bigr) - g^2(\xi)\bigr] \leqslant g(\xi)\omega\bigl(t, g(\xi)\bigr)$$

for each $(t, \xi) \in (\mathbb{I} \setminus \mathbb{Z}) \times \mathbb{V}$, then $\mathbb{K}$ is Carathéodory locally invariant with respect to f.

THEOREM 5.4.3. *Let $\mathbb{D} \subseteq \mathbb{R}^n$ be open and let $f : \mathbb{I} \times \mathbb{D} \to \mathbb{R}^n$. Let us assume that $\mathbb{K} \subseteq \mathbb{D}$ is a Lipschitz retract with the generalized Lipschitz projection $r : \mathbb{V} \to \mathbb{K}$, and there exists a negligible subset $\mathbb{Z}$ of $\mathbb{I}$ satisfying*

$$\liminf_{h \downarrow 0} \frac{1}{h}\bigl\|r\bigl(\xi + hf(t,\xi)\bigr) - \xi - hf(t,\xi)\bigr\| = 0 \tag{5.4.2}$$

for each $(t, \xi) \in (\mathbb{I} \setminus \mathbb{Z}) \times \mathbb{K}$. Assume further that there exists a Carathéodory comparison function $\omega : \mathbb{I} \times [0, a) \to \mathbb{R}$, with $a = \sup_{\xi \in \mathbb{V}} \|r(\xi) - \xi\|$, such that

$$\begin{aligned}&\liminf_{h \downarrow 0} \frac{1}{h}\bigl\langle r\bigl(\xi + hf(t,\xi)\bigr) - r(\xi) - hf(t,\xi), r(\xi) - \xi\bigr\rangle \\ &\quad \leqslant \bigl\|r(\xi) - \xi\bigr\|\omega\bigl(t, \bigl\|r(\xi) - \xi\bigr\|\bigr)\end{aligned}$$

for each $(t, \xi) \in (\mathbb{I} \setminus \mathbb{Z}) \times \mathbb{V}$. Then, $\mathbb{K}$ is Carathéodory locally invariant with respect to f.

A consequence of Theorem 5.4.3 is stated below.

THEOREM 5.4.4. *Let* $\mathbb{K} \subseteq \mathbb{D}$ *with* $\mathbb{D}$ *open and let* $f : \mathbb{I} \times \mathbb{D} \to \mathbb{R}^n$. *Let us assume that* $\mathbb{K}$ *is a Lipschitz retract with the generalized Lipschitz projection* $r : \mathbb{V} \to \mathbb{K}$ *and there exists a negligible subset* $\mathbb{Z}$ *of* $\mathbb{I}$ *such that* (5.4.2) *is satisfied. Let us assume, in addition, that, for each* $t \in \mathbb{I} \setminus \mathbb{Z}$ *and* $\xi \in \mathbb{V}$, *there exists the directional derivative,* $r'(\xi)[f(t,\xi)]$, *of* r, *at* ξ *in the direction* $f(t,\xi)$, *and*

$$\big\langle r'(\xi)\big[f(t,\xi)\big] - f(t,\xi), r(\xi) - \xi\big\rangle \leqslant \big\|r(\xi) - \xi\big\|\omega\big(t, \big\|r(\xi) - \xi\big\|\big),$$

where $\omega : \mathbb{I} \times [0,a) \to \mathbb{R}$ *is a Carathéodory comparison function, with*

$$a = \sup_{\xi \in \mathbb{V}} \big\|r(\xi) - \xi\big\|.$$

Then, $\mathbb{K}$ *is Carathéodory locally invariant with respect to* f.

6. Differential inclusions

6.1. *Multifunctions*

In this section we extend some of the previously established results to a more general case allowing the function f to be multivalued. First we introduce two classes of multifunctions. Let $\mathbb{K}$ be a nonempty subset in $\mathbb{R}^n$ and let $F : \mathbb{K} \rightsquigarrow \mathbb{R}^n$ a given mapping with nonempty values.

DEFINITION 6.1.1. The multifunction $F : \mathbb{K} \rightsquigarrow \mathbb{R}^n$ is *upper semicontinuous* (*u.s.c.*) *at* $\xi \in \mathbb{K}$ if for every open neighborhood $\mathbb{V}$ of $F(\xi)$ there exists an open neighborhood $\mathbb{U}$ of ξ such that $F(\eta) \subseteq \mathbb{V}$ for each $\eta \in \mathbb{U} \cap \mathbb{K}$. We say that F is *upper semicontinuous* (*u.s.c.*) *on* $\mathbb{K}$ if it is u.s.c. at each $\xi \in \mathbb{K}$.

DEFINITION 6.1.2. The multifunction $F : \mathbb{K} \rightsquigarrow \mathbb{R}^n$ is *lower semicontinuous* (*l.s.c.*) *at* $\xi \in \mathbb{K}$ if for every open set $\mathbb{V}$ in $\mathbb{R}^n$ with $F(\xi) \cap \mathbb{V} \neq \emptyset$ there exists an open neighborhood $\mathbb{U}$ of ξ such that $F(\eta) \cap \mathbb{V} \neq \emptyset$ for each $\eta \in \mathbb{U} \cap \mathbb{K}$. We say that F is *lower semicontinuous* (*l.s.c.*) *on* $\mathbb{K}$ if it is l.s.c. at each $\xi \in \mathbb{K}$.

The next two lemmas will prove useful later.

LEMMA 6.1.1. *If* $F : \mathbb{K} \rightsquigarrow \mathbb{R}^n$ *is a nonempty and compact valued u.s.c. multifunction, then, for each compact subset* $\mathbb{C}$ *of* $\mathbb{K}$, $\bigcup_{\xi \in \mathbb{C}} F(\xi)$ *is compact. In particular, for each compact subset* $\mathbb{C}$ *of* $\mathbb{K}$, *there exists* $M > 0$ *such that* $\|\eta\| \leqslant M$ *for each* $\xi \in \mathbb{C}$ *and each* $\eta \in F(\xi)$.

PROOF. Let $\mathbb{C}$ be a compact subset in $\mathbb{K}$ and let $\{\mathbb{D}_\sigma;\ \sigma \in \Gamma\}$ be an arbitrary open covering of $\bigcup_{\xi \in \mathbb{C}} F(\xi)$. Since F is compact valued, for each $\xi \in \mathbb{C}$ there exists $n(\xi) \in \mathbb{N}$ such that

$$F(\xi) \subseteq \bigcup_{1 \leqslant k \leqslant n(\xi)} \mathbb{D}_{\sigma_k}.$$

But F is u.s.c. and therefore there exists an open neighborhood $\mathbb{U}(\xi)$ of ξ such that

$$F\big(\mathbb{U}(\xi)\cap\mathbb{K}\big)\subseteq\bigcup_{1\leqslant k\leqslant n(\xi)}\mathbb{D}_{\sigma_k}.$$

The family $\{\mathbb{U}(\xi);\ \xi\in\mathbb{C}\}$ is an open covering of $\mathbb{C}$. As $\mathbb{C}$ is compact, there exists a finite family $\{\xi_1,\xi_2,\dots,\xi_p\}$ in $\mathbb{C}$ such that

$$F(\mathbb{C})\subseteq\bigcup_{1\leqslant j\leqslant p}F\big(\mathbb{U}(\xi_j)\cap\mathbb{K}\big)\subseteq\bigcup_{1\leqslant j\leqslant p}\ \bigcup_{1\leqslant k\leqslant n(\xi_j)}\mathbb{D}_{\sigma_k},$$

and this completes the proof. □

LEMMA 6.1.2. *Let $F:\mathbb{K}\rightsquigarrow\mathbb{R}^n$ be a u.s.c., nonempty, convex, compact valued multifunction, and let $u_m:[0,T]\to\mathbb{K}$ and $f_m\in L^1(0,T;\mathbb{R}^n)$ be such that $f_m(t)\in F(u_m(t))$ for each $m\in\mathbb{N}$ and a.e. for $t\in[0,T]$. If $\lim_m u_m(t)=u(t)$ a.e. for $t\in[0,T]$ and $\lim_m f_m=f$ weakly in $L^1(0,T;\mathbb{R}^n)$, then $f(t)\in F(u(t))$ a.e. for $t\in[0,T]$.*

PROOF. By Mazur's theorem—Dunford–Schwartz [40, Theorem 6, p. 416]—there exists a sequence $(g_m)_m$ of convex combinations of $\{f_k;\ k\geqslant m\}$, i.e. $g_m\in\operatorname{co}\{f_m,f_{m+1},\dots\}$ for each $m\in\mathbb{N}$, which converges strongly in $L^1(0,T;\mathbb{R}^n)$ to f. By a classical result due to Lebesgue, we know that there exists a subsequence (g_{m_p}) of (g_m) which converges almost everywhere on $[0,T]$ to f. Denote by $\mathbb{T}$ the set of all $s\in[0,T]$ such that both $(g_{m_p}(s))_p$ and $(u_m(s))_m$ are convergent to $f(s)$ and to $u(s)$, respectively, and, in addition, $f_m(s)\in F(u_m(s))$ for each $m\in\mathbb{N}$. Clearly $[0,T]\setminus\mathbb{T}$ has null measure. Let $s\in\mathbb{T}$ and let $\mathbb{E}$ be an open half-space in $\mathbb{R}^n$ including $F(u(s))$. Since F is upper semicontinuous at $u(s)$ and $(u_m(s))_m$ converges to $u(s)$, there exists $m(\mathbb{E})$ belonging to $\mathbb{N}$, such that $F(u_m(s))\subseteq\mathbb{E}$ for each $m\geqslant m(\mathbb{E})$. From the relation above, taking into account that $f_m(s)\in F(u_m(s))$ for each $m\in\mathbb{N}$ and a.e. for $s\in[0,T]$, we easily conclude

$$g_{m_p}(s)\in\overline{\operatorname{co}}\bigg(\bigcup_{m\geqslant m(\mathbb{E})}F\big(u_m(s)\big)\bigg)$$

for each $p\in\mathbb{N}$ with $m_p\geq m(\mathbb{E})$. Passing to the limit for $p\to+\infty$ in the relation above we deduce $f(s)\in\overline{\mathbb{E}}$. Since $F(u(s))$ is closed and convex, it is the intersection of all closed half-spaces which include it. So, inasmuch as $\mathbb{E}$ was arbitrary, we, finally, get $f(s)\in F(u(s))$ for each $s\in\mathbb{T}$ and this completes the proof. □

6.2. *Viability with respect to a multifunction*

Let us consider the autonomous differential inclusion

$$u'(t)\in F\big(u(t)\big)\tag{6.2.1}$$

where $F:\mathbb{K}\rightsquigarrow\mathbb{R}^n$ is a given multifunction. By a *solution* of (6.2.1) we mean an absolutely continuous function $u:\mathbb{J}\to\mathbb{K}$, with $\mathbb{J}$ a proper interval, satisfying $u'(t)\in F(u(t))$ a.e. for $t\in\mathbb{J}$.

DEFINITION 6.2.1. We say that $\mathbb{K}$ is *right viable with respect to* F if for each $\xi\in\mathbb{K}$, there exists $T>0$ such that (6.2.1) has at least one solution $u:[0,T]\to\mathbb{K}$ satisfying $u(0)=\xi$.

THEOREM 6.2.1. *Let $\mathbb{K}$ be a locally closed subset in $\mathbb{R}^n$ and $F:\mathbb{K}\rightsquigarrow\mathbb{R}^n$ a u.s.c. nonempty, closed, convex and bounded valued mapping. Then a necessary and sufficient condition in order that $\mathbb{K}$ be right viable with respect to F is the tangency condition*

$$F(\xi)\cap\mathcal{T}_{\mathbb{K}}(\xi)\neq\emptyset \tag{6.2.2}$$

for each $\xi\in\mathbb{K}$.

PROOF. *Necessity*. Since F is upper semicontinuous and has nonempty, closed, convex and bounded values, by virtue of Lemma 6.1.1, we conclude that F is locally bounded. Let $\xi\in\mathbb{K}$ and let $u:[0,T]\to\mathbb{K}$ be a solution to (6.2.1) satisfying $u(0)=\xi$. Let $h\in(0,T]$ and let us define

$$u_h=\frac{1}{h}\int_0^h u'(s)\,\mathrm{d}s.$$

Since F is locally bounded, by diminishing $T>0$ if necessary, we may assume that $\{u'(s);\ s\in[0,T]\}$ is bounded a.e. In other words, there exists $M>0$ such that $\|u'(s)\|\leqslant M$ a.e. for $s\in[0,T]$. This means that the set $\{\|u_h\|;\ h\in(0,T]\}$ is bounded, also by M, and therefore there exists $h_m\downarrow 0$ such that $\eta=\lim_{m\to\infty}u_{h_m}$. Since F is upper semicontinuous at ξ and has convex compact values, we infer that $\eta\in F(\xi)$. Indeed, for each open neighborhood $\mathbb{V}$ of $F(\xi)$ there exists an open neighborhood $\mathbb{U}$ of ξ such that $F(\zeta)\subseteq\mathbb{V}$ for each $\zeta\in\mathbb{K}\cap\mathbb{U}$. Therefore, if $h\in(0,T]$ is sufficiently small, we have $u'(s)\in\mathbb{V}$ a.e. for $s\in(0,h]$. So, $u_h\in\overline{\text{co}}\,\mathbb{V}$. Accordingly $\eta\in\bigcap_{\mathbb{V}\in\mathcal{V}(F(\xi))}\overline{\text{co}}\,\mathbb{V}$, where $\mathcal{V}(F(\xi))$ stands for the set of open neighborhoods of $F(\xi)$. But $F(\xi)$ is convex, and hence $\bigcap_{\mathbb{V}\in\mathcal{V}(F(\xi))}\overline{\text{co}}\,\mathbb{V}=F(\xi)$. To complete the proof of the necessity, it suffices to show that $\eta\in\mathcal{T}_{\mathbb{K}}(\xi)$. To this aim, let us observe that $\xi+hu_h=u(h)\in\mathbb{K}$, and so $\text{dist}(\xi+hu_h;\mathbb{K})=0$. Thus

$$\text{dist}(\xi+h\eta;\mathbb{K})\leqslant\text{dist}(\xi+hu_h;\mathbb{K})+\big\|\xi+hu_h-(\xi+h\eta)\big\|\leqslant h\|u_h-\eta\|.$$

Since η is a limit point of u_h as $h\downarrow 0$, we deduce

$$\liminf_{h\downarrow 0}\frac{1}{h}\,\text{dist}(\xi+h\eta;\mathbb{K})=0$$

which shows that $\eta\in\mathcal{T}_{\mathbb{K}}(\xi)$. The proof of the necessity is complete. □

REMARK 6.2.1. On may ask whether the equivalence between (i) and (ii) in Proposition 2.5.1 can be extended to this framework. Namely, one may ask on the equivalence of the two conditions below:

(j) for each $\xi \in \mathbb{K}$, $F(\xi) \cap \mathcal{C}_{\mathbb{K}}(\xi) \neq \emptyset$,
(jj) for each $\xi \in \mathbb{K}$, $F(\xi) \cap \mathcal{T}_{\mathbb{K}}(\xi) \neq \emptyset$.

The next simple example shows that (j) and (jj) are not equivalent. Namely, take $n = 2$, $\mathbb{K} = \{(x_1, x_2);\ |x_1| \geqslant x_2\}$ and $\mathbb{V} = \{(x_1, 1);\ |x_1| \leqslant 1\}$, and let us define $F : \mathbb{K} \rightsquigarrow \mathbb{R}^2$ by $F(\xi) = \mathbb{V}$, for each $\xi \in \mathbb{K}$. Clearly, F is both u.s.c. and l.s.c., with nonempty, convex, compact values and (jj) holds true. Nevertheless $F(0,0) \cap \mathcal{C}_{\mathbb{K}}((0,0)) = \emptyset$.

We recall that, whenever $F : \mathbb{K} \rightsquigarrow \mathbb{R}^n$ is l.s.c. at $\xi \in \mathbb{K}$, for each $\eta \in F(\xi)$, and each $(\xi_m)_m$ with $\lim_m \xi_m = \xi$, there exist $(\eta_m)_m$ with $\eta_m \in F(\xi_m)$ for each $m \in \mathbb{N}$, and such that $\lim_m \eta_m = \eta$. See, for instance, Cârjă [20, Theorem 2.4, p. 25]. So, from Remark 2.5.1 and Lemma 2.5.1, we deduce:

PROPOSITION 6.2.1. *If $F : \mathbb{K} \rightsquigarrow \mathbb{R}^n$ is l.s.c., then the following conditions are equivalent*:

(i) *for each $\xi \in \mathbb{K}$, $F(\xi) \subseteq \mathcal{C}_{\mathbb{K}}(\xi)$,*
(ii) *for each $\xi \in \mathbb{K}$, $F(\xi) \subseteq \mathcal{T}_{\mathbb{K}}(\xi)$,*
(iii) *for each $\xi \in \mathbb{K}$, $F(\xi) \subseteq \mathcal{B}_{\mathbb{K}}(\xi)$,*

In general, if $\mathcal{G} : \mathbb{K} \rightsquigarrow \mathbb{R}^n$ is such that $\mathcal{C}_{\mathbb{K}}(\xi) \subseteq \mathcal{G}(\xi) \subseteq \mathcal{B}_{\mathbb{K}}(\xi)$ for each $\xi \in \mathbb{K}$, then each one of the conditions above is equivalent to:

(iv) *for each $\xi \in \mathbb{K}$, $F(\xi) \subseteq \mathcal{G}(\xi)$.*

REMARK 6.2.2. The next simple example shows that the equivalence between (i) and (ii) in Proposition 6.2.1 is no longer true if F is u.s.c. Namely, take $n = 2$, $\mathbb{K} = \{(x_1, x_2);\ |x_1| \geqslant x_2\}$ and let us define $F : \mathbb{K} \rightsquigarrow \mathbb{R}^2$ by

$$F(\xi) = \begin{cases} \{(0,0)\} & \text{if } \xi \in \mathbb{K} \setminus \{(0,0)\}, \\ \mathbb{K} & \text{if } \xi = (0,0). \end{cases}$$

Clearly, F is u.s.c. with nonempty, closed values and (ii) holds true. Nevertheless (i) does not hold.

6.3. *Existence of ε-approximate solutions*

The proof of the sufficiency consists in showing that (6.2.2) along with Brezis–Browder Theorem 2.1.1 imply that, for each $\xi \in \mathbb{K}$, there exists at least one sequence of "approximate" solutions to (6.2.1), defined on the same interval, $u_m : [0, T] \to \mathbb{R}^n$, satisfying $u_m(0) = \xi$ for each $m \in \mathbb{N}$, and such that $(u_m)_m$ converges in some sense to a solution u of (6.2.1) satisfying $u(0) = \xi$.

The next lemma represents an existence result concerning "approximate solutions" of (6.2.1) satisfying $u_m(0) = \xi$.

LEMMA 6.3.1. *Let $\mathbb{K}$ be a nonempty and locally closed subset in $\mathbb{R}^n$, and let $F : \mathbb{K} \rightsquigarrow \mathbb{R}^n$ be a nonempty valued mapping which is locally bounded. If $\mathbb{K}$ and F satisfy* (6.2.2) *then for* *each* $\xi \in \mathbb{K}$ *there exist* $\rho > 0$, $T > 0$, $M > 0$ *such that* $\mathbb{K} \cap B(\xi, \rho)$ *is closed, and for each* $\varepsilon \in (0, 1]$ *there exist four functions*: $\sigma : [0, T] \to [0, T]$ *nondecreasing*, $f : [0, T] \to \mathbb{R}^n$ *and* $g : [0, T] \to \mathbb{R}^n$ *measurable, and* $u : [0, T] \to \mathbb{R}^n$ *continuous, satisfying*

(i) $s - \varepsilon \leqslant \sigma(s) \leqslant s$, $u(\sigma(s)) \in \mathbb{K} \cap B(\xi, \rho)$ *and* $f(s) \in F(u(\sigma(s)))$, *a.e. for* $s \in [0, T]$,
(ii) $\|f(s)\| \leqslant M$ *a.e. for* $s \in [0, T]$,
(iii) $u(T) \in \mathbb{K} \cap B(\xi, \rho)$,
(iv) $\|g(s)\| \leqslant \varepsilon$ *a.e. for* $s \in [0, T]$

and

$$u(t) = \xi + \int_0^t f(s)\,\mathrm{d}s + \int_0^t g(s)\,\mathrm{d}s \tag{6.3.1}$$

for each $t \in [0, T]$.

PROOF. Let $\xi \in \mathbb{K}$ be arbitrary, and choose $\rho > 0$, $T > 0$ and $M > 0$ such that $\mathbb{K} \cap B(\xi, \rho)$ is closed,

$$\|\eta\| \leqslant M \tag{6.3.2}$$

for each $x \in \mathbb{K} \cap B(\xi, \rho)$ and $\eta \in F(x)$, and

$$T(M + 1) \leqslant \rho. \tag{6.3.3}$$

This is always possible since $\mathbb{K}$ is locally closed and F is locally bounded. Let $\varepsilon \in (0, 1]$. We start by showing how to define the functions f, g, σ, and u on a sufficiently small interval $[0, \delta]$, $\delta \leqslant T$, and then we will show how to extend them to the whole interval $[0, T]$. We recall that, in view of Proposition 2.3.2, there exist $\delta \in (0, \varepsilon]$, $\eta \in F(\xi)$ and $p \in \mathbb{R}^n$, all depending on ε, with $\|p\| \leqslant \varepsilon$, and satisfying $\xi + \delta(\eta + p) \in \mathbb{K}$. Diminishing δ if necessary, and using (6.3.2), we may also assume that $\|\delta(\eta + p)\| \leqslant \rho$. Let us define $u : [0, \delta] \to \mathbb{R}^n$ by

$$u(t) = \xi + t\eta + tp \tag{6.3.4}$$

for each $t \in [0, \delta]$. By virtue of (6.3.2), u, η and p satisfy

(j) $\eta \in F(u(0))$,
(jj) $\|\eta\| \leqslant M$,
(jjj) $u(\delta) \in \mathbb{K} \cap B(\xi, \rho)$,
(jv) $\|p\| \leqslant \varepsilon$.

Setting $f(s) = \eta$, $g(s) = p$, $\sigma(s) = 0$ for $s \in [0, \delta]$ and u defined by (6.3.4), from (j)–(jv), the fact that $\delta \in (0, \varepsilon]$ and (6.3.4), we can easily see that (σ, f, g, u) satisfies (i)–(iv) and (6.3.1) with T substituted by δ.

Next, we are going to show that, for each $\varepsilon \in (0, 1]$, there exists at least one 4-tuple (σ, f, g, u), whose domain is $[0, T]$, satisfying (i)–(iv) and (6.3.1). To this aim we shall use Brezis–Browder Theorem 2.1.1 as follows. Let $\mathcal{S}$ be the set of all 4-tuples (σ, f, g, u) defined on $[0, a]$ with $a \in (0, T]$ and satisfying (i)–(iv) and (6.3.1) on $[0, a]$. This set is clearly nonempty because (σ, f, g, u), defined as above, belongs to $\mathcal{S}$. On $\mathcal{S}$ we define a binary relation "$\preceq$" as follows. We say that (σ, f, g, u) defined on $[0, a]$ and $(\tilde{\sigma}, \tilde{f}, \tilde{g}, \tilde{u})$ defined on $[0, b]$ satisfy

$$(\sigma, f, g, u) \preceq \left(\tilde{\sigma}, \tilde{f}, \tilde{g}, \tilde{u}\right)$$

if $a \leqslant b$, $\sigma(s) = \tilde{\sigma}(s)$, $f(s) = \tilde{f}(s)$ and $g(s) = \tilde{g}(s)$ a.e. for $s \in [0, a]$. Endowed with "$\preceq$", $\mathcal{S}$ is obviously a preordered set. Let $((\sigma_m, f_m, g_m, u_m))_m$ be a monotone sequence, and let us denote by $[0, a_m]$ the domain of $(\sigma_m, f_m, g_m, u_m)$. Let $a^* = \lim_m a_m$, where $[0, a_m]$ denotes the domain of definition of $(\sigma_m, f_m, g_m, u_m)$. Clearly $a^* \in (0, T]$. We will show that there exists $(\sigma^*, f^*, g^*, u^*) \in \mathcal{S}$, defined on $[0, a^*]$ and satisfying

$$(\sigma_m, f_m, g_m, u_m) \preceq (\sigma^*, f^*, g^*, u^*)$$

for each $m \in \mathbb{N}$. We will prove first that there exists $\lim_m u_m(a_m)$. For each $m, k \in \mathbb{N}$, $m \leqslant k$, we have $u_m(s) = u_k(s)$ for all $s \in [0, a_m]$, and therefore, taking into account (iii), (iv) and (6.3.1), we deduce

$$\begin{aligned}\left\|u_m(a_m) - u_k(a_k)\right\| &\leqslant \int_{a_m}^{a_k} \left\|f_k(s)\right\| \mathrm{d}s + \int_{a_m}^{a_k} \left\|g_k(s)\right\| \mathrm{d}s \\ &\leqslant (M + \varepsilon)|a_k - a_m|\end{aligned}$$

for all $m, k \in \mathbb{N}$, $m \leqslant k$, which proves that there exists $\lim_{m\to\infty} u_m(a_m)$. Since for every $m \in \mathbb{N}$, $u_m(a_m) \in B(\xi, \rho) \cap \mathbb{K}$, and the latter is closed, it readily follows that $\lim_{m\to\infty} u_m(a_m) \in B(\xi, \rho) \cap \mathbb{K}$. In addition, because all the functions in the set $\{\sigma_m;\ m \in \mathbb{N}\}$ are nondecreasing, with values in $[0, a^*]$ and satisfy $\sigma_m(a_m) \leqslant \sigma_p(a_p)$ for every $m, p \in \mathbb{N}$ with $m \leqslant p$, there exists $\lim_{m\to\infty} \sigma_m(a_m)$ and this limit belongs to $[0, a^*]$. This allows us to define the 4-tuple $(\sigma^*, f^*, g^*, u^*) : [0, a^*] \to [0, a^*] \times \mathbb{R}^n \times \mathbb{R}^n \times \mathbb{R}^n$ by

$$\sigma^*(t) = \begin{cases} \sigma_m(t) & \text{for } t \in [0, a_m],\ m \in \mathbb{N}, \\ \lim\limits_{m\to\infty} \sigma_m(a_m) & \text{for } t = a^*, \end{cases}$$

$$f^*(t) = f_m(t) \quad \text{a.e. for } t \in [0, a_m],\ m \in \mathbb{N},$$

$$g^*(t) = \begin{cases} g_m(t) & \text{for } t \in [0, a_m],\ m \in \mathbb{N}, \\ 0 & \text{for } t = a^*, \end{cases}$$

$$u^*(t) = \begin{cases} u_m(t) & \text{for } t \in [0, a_m],\ m \in \mathbb{N}, \\ \lim\limits_{m\to\infty} u_m(a_m) & \text{for } t = a^*. \end{cases}$$

One can easily see that $(\sigma^*, f^*, g^*, u^*)$ is an ε-approximate solution which is a majorant for $((\sigma_m, f_m, g_m, u_m))_m$. Let us define $\mathcal{M} : \mathcal{S} \to \mathbb{R} \cup \{+\infty\}$ by $\mathcal{M}((\sigma, f, g, u)) = c$, where $[0, c]$ is the domain of definition of (σ, f, g, u). Clearly $\mathcal{M}$ satisfies the hypotheses of Brezis–Browder Theorem 2.1.1. Then, there exists an $\mathcal{M}$-maximal element

$(\bar{\sigma}, \bar{f}, \bar{g}, \bar{u}) \in \mathcal{S}$, defined on $[0, \bar{c}]$. This means that if $(\tilde{\sigma}, \tilde{f}, \tilde{g}, \tilde{u}) \in \mathcal{S}$ is defined on $[0, \tilde{c}]$ and $(\bar{\sigma}, \bar{f}, \bar{g}, \bar{u}) \preceq (\tilde{\sigma}, \tilde{f}, \tilde{g}, \tilde{u})$, we have $\mathcal{M}((\bar{\sigma}, \bar{f}, \bar{g}, \bar{u})) = \mathcal{M}((\tilde{\sigma}, \tilde{f}, \tilde{g}, \tilde{u}))$. We will show next that $\bar{c} = T$. Indeed, let us assume by contradiction that $\bar{c} < T$. We have

$$\begin{aligned}\left\|\bar{u}(\bar{c}) - \xi\right\| &\leqslant \int_0^{\bar{c}} \left\|\bar{f}(s)\right\| \mathrm{d}s + \int_0^{\bar{c}} \left\|\bar{g}(s)\right\| \mathrm{d}s \leqslant \bar{c}(M + \varepsilon)\\ &\leqslant \bar{c}(M + 1) < \rho.\end{aligned}$$

Then, as $\bar{u}(\bar{c}) \in \mathbb{K}$, by virtue of (6.2.2), there exists $f_{\bar{c}} \in F(\bar{u}(\bar{c})) \cap \mathcal{T}_{\mathbb{K}}(\bar{u}(\bar{c}))$. This means that, there exist $\delta \in (0, T - \bar{c})$, $\delta \leqslant \varepsilon$ and $p \in \mathbb{R}^n$ such that $\|p\| \leqslant \varepsilon$ and $\bar{u}(\bar{c}) + \delta f_{\bar{c}} + \delta p \in \mathbb{K}$. From the inequality above, it follows that we can diminish δ if necessary, in order to have $\|\bar{u}(\bar{c}) + \delta(f_{\bar{c}} + p) - \xi\| \leqslant \rho$. Let us define the functions $\sigma : [0, \bar{c} + \delta] \to [0, \bar{c} + \delta]$, $f : [0, \bar{c} + \delta] \to \mathbb{R}^n$ and $g : [0, \bar{c} + \delta] \to \mathbb{R}^n$ by

$$\sigma(t) = \begin{cases} \bar{\sigma}(t) & \text{for } t \in [0, \bar{c}],\\ \bar{c} & \text{for } t \in (\bar{c}, \bar{c} + \delta],\end{cases}$$

$$f(t) = \begin{cases} \bar{f}(t) & \text{a.e. for } t \in [0, \bar{c}],\\ f_{\bar{c}} & \text{a.e. for } t \in (\bar{c}, \bar{c} + \delta],\end{cases}$$

$$g(t) = \begin{cases} \bar{g}(t) & \text{for } t \in [0, \bar{c}],\\ p & \text{for } t \in (\bar{c}, \bar{c} + \delta].\end{cases}$$

It is not difficult to see that σ is nondecreasing, f and g are measurable on $[0, \bar{c} + \delta]$ and $\|g(t)\| \leqslant \varepsilon$ for every $t \in [0, \bar{c} + \delta]$. We define $u : [0, \bar{c} + \delta] \to \mathbb{R}^n$ by

$$u(t) = \xi + \int_0^t f(s)\,\mathrm{d}s + \int_0^t g(s)\,\mathrm{d}s$$

for every $t \in [0, \bar{c} + \delta]$. Clearly u coincides with $\bar{u}$ on $[0, \bar{c}]$ and then it readily follows that σ, f, g and u satisfy all the conditions in (i) and (ii). In order to prove (iii) and (iv), let us observe that

$$u(t) = \begin{cases} \bar{u}(t) & \text{for } t \in [0, \bar{c}],\\ \bar{u}(\bar{c}) + (t - \bar{c})f_{\bar{c}} + (t - \bar{c})p & \text{for } t \in [\bar{c}, \bar{c} + \delta].\end{cases}$$

As $u(\bar{c} + \delta) = \bar{u}(\bar{c}) + \delta f_{\bar{c}} + \delta p \in \mathbb{K}$, from the choice of δ, we also have $u(\bar{c} + \delta) \in \mathbb{K} \cap B(\xi, \rho)$. So, although $(\bar{\sigma}, \bar{f}, \bar{g}, \bar{u})$ is $\mathcal{M}$-maximal, we have both $(\bar{\sigma}, \bar{f}, \bar{g}, \bar{u}) \preceq (\sigma, f, g, u)$, and $\mathcal{M}((\bar{\sigma}, \bar{f}, \bar{g}, \bar{u})) < \mathcal{M}((\sigma, f, g, u))$, which is absurd. This contradiction can be eliminated only if each maximal element in the set $\mathcal{S}$ is defined on $[0, T]$, and this completes the proof of Lemma 6.3.1. □

6.4. *Convergence of the ε-approximate solutions*

DEFINITION 6.4.1. Let $\xi \in \mathbb{K}$ and $\varepsilon \in (0, 1]$. A 4-tuple (σ, f, g, u) satisfying (i)–(iv) and (6.3.1) is called an *ε-approximate solution* of (6.2.1).

We are now prepared to prove the sufficiency of Theorem 6.2.1.

PROOF. Let $\varepsilon_m \downarrow 0$ and, for each $m \in \mathbb{N}$, let us fix an ε_m-approximate solution $(\sigma_m, f_m, g_m, u_m)$ of (6.2.1) defined on $[0, T]$.

Since, by (iv), $\|g_m(t)\| \leqslant \varepsilon_m$ for each $m \in \mathbb{N}$ and $t \in [0, T]$, we have

$$\lim_{m\to\infty} \int_0^t g_m(s)\, \mathrm{d}s = 0$$

uniformly for $t \in [0, T]$. Moreover, as for each $m \in \mathbb{N}$, f_m satisfies (ii), we may assume with no loss of generality (by extracting a subsequence if necessary) that there exists $f \in L^1(0, T; \mathbb{R}^n)$ such that

$$\lim_{m\to\infty} f_m = f$$

weakly in $L^1(0, T; \mathbb{R}^n)$. As a consequence, from (6.3.1), we infer that there exists $u : [0, T] \to \mathbb{R}^n$ such that

$$\lim_{m\to\infty} u_m(t) = u(t)$$

uniformly for $t \in [0, T]$. Also from (6.3.1) and the last three relations, we easily conclude that

$$u(t) = \xi + \int_0^t f(s)\, \mathrm{d}s$$

for each $t \in [0, T]$. Recalling that, by (i), we have $s - \varepsilon_m \leqslant \sigma_m(s) \leqslant s$ for each $m \in \mathbb{N}$ and a.e. for $s \in [0, T]$, from the remarks above, we obtain

$$\lim_{m\to\infty} u_m\bigl(\sigma_m(s)\bigr) = u(s)$$

a.e. for $s \in [0, T]$. Furthermore, again by (i), $u_m(\sigma_m(s)) \in \mathbb{K} \cap B(\xi, \rho)$ a.e. for $s \in [0, T]$ and since $\mathbb{K} \cap B(\xi, \rho)$ is closed, we have $u(s) \in \mathbb{K}$ a.e. for $s \in [0, T]$. Since u is continuous, using once again the fact that $\mathbb{K} \cap B(\xi, \rho)$ is closed, we deduce that $u(s) \in \mathbb{K} \cap B(\xi, \rho)$ for each $s \in [0, T]$. Finally, since F is upper semicontinuous with nonempty, convex and compact values, by virtue of Lemma 6.1.2, we conclude that $f(s) \in F(u(s))$ a.e. for $s \in [0, T]$, and thus u is a solution to (6.2.1) and $u(0) = \xi$. The proof is complete. □

6.5. *Noncontinuable solutions*

In this section we will prove some results concerning the existence of noncontinuable, or even global solutions to (6.2.1). We recall that a solution $u : [0, T) \to \mathbb{K}$ of (6.2.1) is called *noncontinuable* if there is no other solution $v : [0, \widetilde{T}) \to \mathbb{K}$ of (6.2.1), with $T < \widetilde{T}$, satisfying $u(t) = v(t)$ for all $t \in [0, T)$. The next theorem is a consequence of Brezis–Browder Theorem 2.1.1.

THEOREM 6.5.1. *Let* $\mathbb{K}$ *be a nonempty and locally closed subset in* $\mathbb{R}^n$, *and let* $F : \mathbb{K} \rightsquigarrow \mathbb{R}^n$ *be a u.s.c., nonempty, closed, convex and bounded valued mapping. Then, a necessary and sufficient condition in order that for each* $\xi \in \mathbb{K}$ *to exist at least one noncontinuable solution to* (6.2.1) *satisfying* $u(0) = \xi$ *is the tangency condition* (6.2.2).

PROOF. The necessity is an easy consequence of Theorem 6.2.1. As concerns the sufficiency, let $\xi \in \mathbb{K}$ and let $u : [0, T) \to \mathbb{K}$ a solution to (6.2.1) satisfying $u(0) = \xi$. The existence of this solution is guaranteed by Theorem 6.2.1. To complete the proof it suffices to show that u can be continued up to a noncontinuable one. To this aim, we will make use of Brezis–Browder Theorem 2.1.1. Let $\mathcal{S}$ be the set of all solutions to (6.2.1), defined at least and coinciding with u on $[0, T)$. On $\mathcal{S}$, we define the binary relation "$\preceq$" by $u \preceq v$ if the domain $[0, T_v)$ of v is larger that the domain $[0, T_u)$ of u, i.e. $T_u \leqslant T_v$, and $u(t) = v(t)$ for all $t \in [0, T_u)$. Clearly "$\preceq$" is a preorder on $\mathcal{S}$. Next, let $(u_m)_m$ be an increasing sequence in $\mathcal{S}$, and let us denote by $[0, T_m)$ the domain of definition of u_m. Let $T^* = \lim_{m\to\infty} T_m$, which can be finite, or not, and let us define $u^* : [0, T^*) \to \mathbb{K}$ by $u^*(t) = u_m(t)$ for each $t \in [0, T_m)$. Since $(T_m)_m$ is increasing and $u_m(t) = u_k(t)$ for each $m \leqslant k$ and each $t \in [0, T_m)$, u^* is well-defined and belongs to $\mathcal{S}$. Moreover, u^* is a majorant of u_m for each $m \in \mathbb{N}$. Thus each increasing sequence in $\mathcal{S}$ is bounded from above. Moreover, the function $\mathcal{M} : \mathcal{S} \to \mathbb{R} \cup \{+\infty\}$, defined by $\mathcal{M}(v) = T_v$, for each $v \in \mathcal{S}$, is monotone, and therefore we are in the hypotheses of Theorem 2.1.1. Accordingly, there exists at least one $\mathcal{M}$-maximal element $\bar{u} \in \mathcal{S}$. But this means that $\bar{u}$ is noncontinuable, and, of course, that it extends u. The proof is complete. □

We need next a multivalued counterpart of Definition 3.5.1.

DEFINITION 6.5.1. A mapping $F : \mathbb{K} \rightsquigarrow \mathbb{R}^n$ is called *positively sublinear* if there exist a norm $\|\cdot\|$ on $\mathbb{R}^n$, $a > 0$, $b \in \mathbb{R}$, and $c > 0$ such that

$$\sup\bigl\{\|\eta\|;\ \eta \in F(\xi)\bigr\} \leqslant a\|\xi\| + b$$

for each $\xi \in \mathbb{K}_+^c(F)$, where

$$\mathbb{K}_+^c(F) = \Bigl\{\xi \in \mathbb{K};\ \|\xi\| > c \text{ and } \sup_{\eta\in F(\xi)} [\xi, \eta]_+ > 0\Bigr\}.$$

As concerns the existence of global solutions to (6.2.1), we have:

THEOREM 6.5.2. *Let* $\mathbb{K} \subseteq \mathbb{R}^n$ *be nonempty and closed, and let* $F : \mathbb{K} \rightsquigarrow \mathbb{R}^n$ *be a u.s.c., nonempty, closed, convex and bounded valued mapping which is positively sublinear. Then, a necessary and sufficient condition in order that for each* $\xi \in \mathbb{K}$ *there exists at least one global solution to* (6.2.1) *satisfying* $u(0) = \xi$ *is the tangency condition* (6.2.2).

PROOF. Let $\xi \in \mathbb{K}$ and let $u : [0, T) \to \mathbb{K}$ be a noncontinuable solution to (6.2.1) satisfying $u(0) = \xi$. We will show that $T = +\infty$. To this aim, let us assume the contrary, i.e., that $T < +\infty$. Since $u'(s) \in F(u(t))$ a.e. for $s \in [0, T)$, we deduce

$$\big[u(s), u'(s)\big]_+ \leqslant \sup_{\eta \in F(u(s))} \big[u(s), \eta\big]_+.$$

Observing that $[u(s), u'(s)] = \frac{\mathrm{d}}{\mathrm{d}s}(\|u(s)\|)$ a.e. for $s \in [0, T)$, where $\|\cdot\|$ is the norm in Definition 6.5.1, integrating from 0 to t the last equality, we obtain

$$\big\|u(t)\big\| \leqslant \|\xi\| + \int_0^t \sup_{\eta \in F(u(s))} \big[u(s), \eta\big]_+ \,\mathrm{d}s.$$

Denoting by $M = \sup\{\|\eta\|;\ \eta \in F(v),\ \|v\| \leqslant c\}$ and by λ the Lebesgue measure on $\mathbb{R}$, by the positive sublinearity of F and Lemma 6.1.1 we get

$$\begin{aligned}
\big\|u(t)\big\| &\leqslant \|\xi\| + \int_{\{s \leqslant t;\, \|u(s)\| \leqslant c\}} \sup_{\eta \in F(u(s))} \big[u(s), \eta\big]_+ \,\mathrm{d}s \\
&\quad + \int_{\{s \leqslant t;\, \|u(s)\| > c\}} \sup_{\eta \in F(u(s))} \big[u(s), \eta\big]_+ \,\mathrm{d}s \\
&\leqslant \|\xi\| + M\lambda\big(\big\{s \leqslant t;\ \big\|u(s)\big\| \leqslant c\big\}\big) + \int_{\{s \leqslant t;\, \|u(s)\| > c\}} \big[a\big\|u(s)\big\| + b\big] \,\mathrm{d}s \\
&\leqslant \|\xi\| + (b + M)T + a\int_0^t \big\|u(s)\big\| \,\mathrm{d}s.
\end{aligned}$$

So, by Gronwall's Inequality, we deduce that u is bounded on $[0, T)$. Again from Lemma 6.1.1, it follows that the set $\{\eta;\ \eta \in F(u(t)),\ t \in [0, T)\}$ is bounded. Therefore u is globally Lipschitz on $[0, T)$ and accordingly there exists $\lim_{t \uparrow T} u(t) = u^*$. Since $\mathbb{K}$ is closed, it follows that $u^* \in \mathbb{K}$. Using this observation and recalling that (6.2.2) is satisfied, we conclude that u can be continued to the right of T, which is absurd as long as u is noncontinuable. This contradiction can be eliminated only if $T = +\infty$, and this completes the proof. □

Noticing that, in view of Lemma 6.1.1, whenever $\mathbb{K}$ is compact, each upper semicontinuous, compact valued mapping $F : \mathbb{K} \rightsquigarrow \mathbb{R}^n$ is bounded, and thus positively sublinear, from Theorem 6.5.2, we deduce:

COROLLARY 6.5.1. *Let $\mathbb{K} \subseteq \mathbb{R}^n$ be nonempty and compact, and let $F : \mathbb{K} \rightsquigarrow \mathbb{R}^n$ be a u.s.c., nonempty, closed, convex and bounded valued mapping. Then, a necessary and sufficient condition in order that for each $\xi \in \mathbb{K}$ to exist at least one global solution, $u : [0, +\infty) \to \mathbb{K}$ of* (6.2.1), *satisfying $u(0) = \xi$ is the tangency condition* (6.2.2).

6.6. *Viable preordered subsets*

As in Section 3.8, let us consider $\mathbb{K}$ a nonempty subset in $\mathbb{R}^n$, and let "$\preceq$" be a preorder on $\mathbb{K}$, identified with the multifunction $\mathcal{P} : \mathbb{K} \rightsquigarrow \mathbb{K}$, defined by

$$\mathcal{P}(\xi) = \{\eta \in \mathbb{K};\ \xi \preceq \eta\}$$

for each $\xi \in \mathbb{K}$, and called also a preorder. Let $F : \mathbb{K} \rightsquigarrow \mathbb{R}^n$ be a multifunction. We say that "$\preceq$", or $\mathcal{P}$, is *viable with respect to* F if for each $\xi \in \mathbb{K}$, there exist $T > 0$ and a solution $u : [0, T] \to \mathbb{R}^n$ of the differential inclusion (6.2.1) satisfying $u(\tau) = \xi$, $u(t) \in \mathbb{K}$ for each $t \in [0, T]$ and u is "$\preceq$"-monotone on $[\tau, T]$, i.e., for each $\tau \leqslant s \leqslant t \leqslant T$, we have $u(s) \preceq u(t)$. An autonomous multivalued counterpart of Lemma 3.8.1 is proved below. See Cârjă and Ursescu [25].

LEMMA 6.6.1. *Let $F : \mathbb{K} \rightsquigarrow \mathbb{R}^n$ and let $\mathcal{P}$ be a preorder on $\mathbb{K}$. If $\mathcal{P}$ is viable with respect to F then, for each $\xi \in \mathbb{K}$, $\mathcal{P}(\xi)$ is viable with respect to F. If $\mathcal{P}$ is closed in $\mathbb{R}^n \times \mathbb{R}^n$ and, for each $\xi \in \mathbb{K}$, $\mathcal{P}(\xi)$ is viable with respect to F, then $\mathcal{P}$ is viable with respect to F.*

The proof follows the very same lines as that one of Lemma 3.8.1, and therefore we do not enter into details.

THEOREM 6.6.1. *Let $\mathcal{P}$ be a closed preorder on $\mathbb{K}$ and let $F : \mathbb{K} \rightsquigarrow \mathbb{R}^n$ be u.s.c. with nonempty, compact and convex values. Then a necessary and sufficient condition in order that $\mathcal{P}$ be viable with respect to F is the tangency condition below*:

$$F(\xi) \cap \mathcal{T}_{\mathcal{P}(\xi)}(\xi) \neq \emptyset$$

for each $\xi \in \mathbb{K}$.

PROOF. The proof follows immediately from Lemma 6.6.1. □

6.7. *Local invariance. Sufficient conditions*

Let $\mathbb{D}$ be a domain in $\mathbb{R}^n$, $\mathbb{K} \subseteq \mathbb{D}$ a locally closed subset, and let us consider the differential inclusion (6.2.1), where $F : \mathbb{D} \rightsquigarrow \mathbb{R}^n$ is a given multifunction.

DEFINITION 6.7.1. The subset $\mathbb{K}$ is *locally invariant* with respect to F if for each $\xi \in \mathbb{K}$ and each solution $u : [0, c] \to \mathbb{D}$, $c > 0$, of (6.2.1), satisfying the initial condition $u(0) = \xi$, there exists $T \in (0, c]$ such that we have $u(t) \in \mathbb{K}$ for each $t \in [0, T]$. It is *invariant* if it satisfies the local invariance condition above with $T = c$.

REMARK 6.7.1. If F is upper semicontinuous and nonempty, convex and compact valued on $\mathbb{D}$ and $\mathbb{K}$ is locally invariant with respect to F, then $\mathbb{K}$ is viable with respect to F. The converse of this assertion is no longer true, as we already have seen, even in the single-valued case. See Example 4.1.1.

Our first sufficient condition for local invariance is expressed in terms of the exterior tangency condition below, extending its single-valued counterpart (1.1.6), i.e., there exists an open neighborhood $\mathbb{V}$ of $\mathbb{K}$, with $\mathbb{V} \subseteq \mathbb{D}$, such that

$$\liminf_{h \downarrow 0} \frac{1}{h}\big[\operatorname{dist}(\xi + h\eta; \mathbb{K}) - \operatorname{dist}(\xi; \mathbb{K})\big] \leqslant \omega\big(\operatorname{dist}(\xi; \mathbb{K})\big) \tag{6.7.1}$$

for each $\xi \in \mathbb{V}$ and each $\eta \in F(\xi)$, where ω is an "autonomous" comparison function, i.e. a comparison function which does not depend on t. The main result in this section is:

THEOREM 6.7.1. *Let $\mathbb{K} \subseteq \mathbb{D} \subseteq \mathbb{R}^n$, with $\mathbb{K}$ locally closed and $\mathbb{D}$ open, and let $F : \mathbb{D} \rightsquigarrow \mathbb{R}^n$. If* (6.7.1) *is satisfied, then $\mathbb{K}$ is locally invariant with respect to F.*

PROOF. Let $\mathbb{V} \subseteq \mathbb{D}$ be the open neighborhood of $\mathbb{K}$ whose existence is ensured by (6.7.1) and let $\omega : [0, a) \to \mathbb{R}$ the corresponding comparison function. Let $\xi \in \mathbb{K}$ and let $u : [0, c] \to \mathbb{V}$ be any local solution to (6.2.1) satisfying $u(0) = \xi$. Diminishing c if necessary, we may assume that there exists $\rho > 0$ such that $B(\xi, \rho) \cap \mathbb{K}$ is closed, $u(t) \in B(\xi, \rho/2)$ and, in addition, $\operatorname{dist}(u(t); \mathbb{K}) < a$ for each $t \in [0, c]$. Let $g : [0, c] \to \mathbb{R}_+$ be defined by $g(t) = \operatorname{dist}(u(t); \mathbb{K})$ for each $t \in [0, c]$. Let us observe that g is absolutely continuous on $[0, c]$. Let $t \in [0, c)$ be such that both $u'(t)$ and $g'(t)$ exist and $u'(t) \in F(u(t))$, and let $h > 0$ with $t + h \in [0, c]$. We have

$$\begin{aligned} g(t+h) &= \operatorname{dist}\big(u(t+h); \mathbb{K}\big) \\ &\leqslant h\left\|\frac{u(t+h) - u(t)}{h} - u'(t)\right\| + \operatorname{dist}\big(u(t) + hu'(t); \mathbb{K}\big). \end{aligned}$$

Therefore

$$\frac{g(t+h) - g(t)}{h} \leqslant \alpha(h) + \frac{\operatorname{dist}(u(t) + hu'(t); \mathbb{K}) - \operatorname{dist}(u(t); \mathbb{K})}{h},$$

where

$$\alpha(h) = \left\|\frac{u(t+h) - u(t)}{h} - u'(t)\right\|.$$

Since $\lim_{h \downarrow 0} \alpha(h) = 0$, passing to the inf-limit for $h \downarrow 0$ and taking into account that $\mathbb{V}$, $\mathbb{K}$ and F satisfy (6.7.1), we get

$$[D_+ g](t) \leqslant \omega\big(g(t)\big)$$

a.e. for $t \in [0, c)$. So, $g(t) \equiv 0$ which means that $u(t) \in \overline{\mathbb{K}} \cap B(\xi, \rho/2)$ for all $t \in [0, c)$. But $\overline{\mathbb{K}} \cap B(\xi, \rho/2) \subset \mathbb{K} \cap B(\xi, \rho)$ for each $t \in [0, c)$, and this completes the proof. □

REMARK 6.7.2. One may easily see that (6.7.1) is satisfied with $\omega = \omega_F$, where the function $\omega_F : [0,a) \to \overline{\mathbb{R}}$, $a = \sup_{\xi\in\mathbb{V}} \operatorname{dist}(\xi;\mathbb{K})$, is defined by

$$\omega_F(x) = \sup_{\substack{\xi\in\mathbb{V}\\ \operatorname{dist}(\xi;\mathbb{K})=x}} \ \sup_{\eta\in F(\xi)} \liminf_{h\downarrow 0} \frac{1}{h}\bigl[\operatorname{dist}(\xi+h\eta;\mathbb{K}) - \operatorname{dist}(\xi;\mathbb{K})\bigr] \tag{6.7.2}$$

for each $x \in [0,a)$.

So, Theorem 6.7.1 can be reformulated as:

THEOREM 6.7.2. *Let $\mathbb{K} \subseteq \mathbb{D} \subseteq \mathbb{R}^n$, with $\mathbb{K}$ locally closed and $\mathbb{D}$ open, and let $F : \mathbb{D} \rightsquigarrow \mathbb{R}^n$. If there exists an open neighborhood V of $\mathbb{K}$ with $\mathbb{V} \subseteq \mathbb{D}$ such that ω_F defined by* (6.7.2) *is a comparison function, then $\mathbb{K}$ is locally invariant with respect to F.*

6.8. *Local invariance. Necessary conditions*

We begin with the following simple necessary condition for local invariance.

THEOREM 6.8.1. *Let $\mathbb{K} \subseteq \mathbb{D} \subseteq \mathbb{R}^n$, with $\mathbb{K}$ nonempty and $\mathbb{D}$ open, and let $F : \mathbb{D} \rightsquigarrow \mathbb{R}^n$ be l.s.c. with nonempty, convex and compact values. If $\mathbb{K}$ is locally invariant with respect to F, then, for each $\xi \in \mathbb{K}$, $F(\xi) \subseteq \mathcal{C}_{\mathbb{K}}(\xi)$.*

PROOF. Let $\xi \in \mathbb{K}$ and $\eta \in F(\xi)$. Since F is l.s.c. with nonempty, closed and convex values, by the Michael' selection theorem [67,68], there exists a continuous function $f : \mathbb{D} \to \mathbb{R}^n$ such that $f(\xi) = \eta$ and $f(x) \in F(x)$ for each $x \in \mathbb{D}$. As $\mathbb{D}$ is open, by Peano's local existence theorem 1.1.1, there exists at least one solution $u : [0,T] \to \mathbb{D}$ of the equation $u'(t) = f(u(t))$ satisfying $u(0) = \xi$. Clearly $u'(0) = f(u(0)) = \eta$ and, in addition, u is a solution to the differential inclusion (6.2.1). Since $\xi \in \mathbb{K}$ and the latter is locally invariant with respect to F, there exists $0 < a \leqslant T$ such that $u(t) \in \mathbb{K}$ for all $t \in [0,a]$. Now, repeating the same arguments as in the proof of Theorem 3.2.1—Section 3.2—we conclude that $\eta = u'(0) \in \mathcal{F}_{\mathbb{K}}(\xi)$. The conclusion follows from Proposition 6.2.1, and the proof is complete. □

Next, we rephrase some concepts we introduced in the single-valued case.

DEFINITION 6.8.1. Let $\mathbb{K} \subseteq \mathbb{D} \subseteq \mathbb{R}^n$. A multifunction $F : \mathbb{D} \rightsquigarrow \mathbb{R}^n$ has *the comparison property with respect to* $(\mathbb{D},\mathbb{K})$ if there exist a proximal neighborhood $\mathbb{V} \subseteq \mathbb{D}$ of $\mathbb{K}$, one projection $\pi_{\mathbb{K}} : \mathbb{V} \to \mathbb{K}$ subordinated to $\mathbb{V}$, and one comparison function

$$\omega : [0,a) \to \mathbb{R}, \quad \text{with } a = \sup_{\xi\in\mathbb{V}} \operatorname{dist}(\xi;\mathbb{K}),$$

such that

$$\sup_{\eta\in F(\xi)} \ \inf_{\eta_\pi\in F(\pi_K(\xi))} \bigl[\xi - \pi_{\mathbb{K}}(\xi), \eta - \eta_\pi\bigr]_+ \leqslant \omega\bigl(\bigl\|\xi - \pi_{\mathbb{K}}(\xi)\bigr\|\bigr) \tag{6.8.1}$$

for each $\xi \in \mathbb{V}$.

A condition similar to that one in Definition 6.8.1, with ξ replaced by ξ_1 and $\pi_{\mathbb{K}}(\xi)$ replaced by ξ_2 with $\xi_1, \xi_2 \in \mathbb{V}$, has been used previously by Cârjă and Ursescu [25]. As in the single-valued case, here, (6.8.1) is also automatically satisfied for each $\xi \in \mathbb{K}$, and therefore, in Definition 6.8.1, we have only to assume that (6.8.1) holds for each $\xi \in \mathbb{V} \setminus \mathbb{K}$.

DEFINITION 6.8.2. The multifunction $F : \mathbb{D} \rightsquigarrow \mathbb{R}^n$ is called:

(i) $(\mathbb{D}, \mathbb{K})$-*Lipschitz* if there exist a proximal neighborhood $\mathbb{V} \subseteq \mathbb{D}$ of $\mathbb{K}$, a subordinated projection $\pi_{\mathbb{K}} : \mathbb{V} \to \mathbb{K}$, and $L > 0$, such that

$$\sup_{\eta \in F(\xi)} \inf_{\eta_\pi \in F(\pi_K(\xi))} \|\eta - \eta_\pi\| \leqslant L \big\| \xi - \pi_{\mathbb{K}}(\xi) \big\|$$

for each $\xi \in \mathbb{V} \setminus \mathbb{K}$;

(ii) $(\mathbb{D}, \mathbb{K})$-*dissipative* if there exist a proximal neighborhood $\mathbb{V} \subset \mathbb{D}$ of $\mathbb{K}$, and a projection, $\pi_{\mathbb{K}} : \mathbb{V} \to \mathbb{K}$, subordinated to $\mathbb{V}$, such that

$$\sup_{\eta \in F(\xi)} \inf_{\eta_\pi \in F(\pi_K(\xi))} \big[\xi - \pi_{\mathbb{K}}(\xi), \eta - \eta_\pi \big]_+ \leqslant 0$$

for each $\xi \in \mathbb{V} \setminus \mathbb{K}$.

A strictly more restrictive Lipschitz condition, with ξ replaced by ξ_1 and $\pi_K(\xi)$ by ξ_2, with ξ_1, ξ_2 belonging to $\mathbb{D}$, has been considered first by Filippov [43]. In a very same spirit as Filippov [43], Kobayashi [62] has used a dissipative type condition strictly restrictive than that one in Definition 6.8.2. It is easy to see that if F is either $(\mathbb{D}, \mathbb{K})$-Lipschitz, or $(\mathbb{D}, \mathbb{K})$-dissipative, then it has the comparison property with respect to $(\mathbb{D}, \mathbb{K})$. We notice that there are examples showing that there exist multifunctions F which, although neither $(\mathbb{D}, \mathbb{K})$-Lipschitz, nor $(\mathbb{D}, \mathbb{K})$-dissipative, have the comparison property. See, for instance, the “single-valued” Examples 4.3.1 and 4.3.2.

THEOREM 6.8.2. *Let $\mathbb{K} \subseteq \mathbb{D} \subseteq \mathbb{R}^n$, with $\mathbb{K}$ locally closed and $\mathbb{D}$ open, and let $F : \mathbb{D} \rightsquigarrow \mathbb{R}^n$ be a multifunction. If F has the comparison property with respect to* $(\mathbb{D}, \mathbb{K})$, *and*

$$\liminf_{h \downarrow 0} \frac{1}{h} \operatorname{dist}(\xi + h\eta; \mathbb{K}) = 0 \tag{6.8.2}$$

for each $\xi \in \mathbb{K}$ and each $\eta \in F(\xi)$, then (6.7.1) *holds true.*

PROOF. Let $\mathbb{V} \subseteq \mathbb{D}$ be the open neighborhood of $\mathbb{K}$ as in Definition 6.8.1, let $\xi \in \mathbb{V}$ and $\eta \in F(\xi)$. Let $\rho > 0$ and let $\pi_{\mathbb{K}}$ be the selection of $\Pi_{\mathbb{K}}$ as in Definition 6.8.1. Let $h \in (0, T]$. Since $\|\xi - \pi_{\mathbb{K}}(\xi)\| = \operatorname{dist}(\xi; \mathbb{K})$, we have

$$\begin{aligned} &\operatorname{dist}(\xi + h\eta; \mathbb{K}) - \operatorname{dist}(\xi; \mathbb{K}) \\ &\quad \leqslant \big\| \xi - \pi_{\mathbb{K}}(\xi) + h[\eta - \zeta] \big\| - \big\| \xi - \pi_{\mathbb{K}}(\xi) \big\| + d\big(\pi_{\mathbb{K}}(\xi) + h\zeta; \mathbb{K}\big), \end{aligned}$$

for each $\zeta \in F(\pi_{\mathbb{K}}(\xi))$.

Dividing by h, passing to the lim inf for $h \downarrow 0$, and using (6.8.2), we get

$$\liminf_{h\downarrow 0} \frac{1}{h}\big[\operatorname{dist}(\xi + h\eta; \mathbb{K}) - \operatorname{dist}(\xi; \mathbb{K})\big] \leqslant \big[\xi - \pi_{\mathbb{K}}(\xi), \eta - \zeta\big]_+.$$

Since $\zeta \in F(\pi_{\mathbb{K}}(\xi))$ is arbitrary, we have

$$\liminf_{h\downarrow 0} \frac{1}{h}\big[\operatorname{dist}(\xi + h\eta; \mathbb{K}) - \operatorname{dist}(\xi; \mathbb{K})\big] \leqslant \inf_{\zeta\in F(\pi_{\mathbb{K}}(\xi))}\big[\xi - \pi_{\mathbb{K}}(\xi), \eta - \zeta\big]_+.$$

Therefore

$$\liminf_{h\downarrow 0} \frac{1}{h}\big[\operatorname{dist}(\xi + h\eta; \mathbb{K}) - \operatorname{dist}(\xi; \mathbb{K})\big] \leqslant \omega\big(\big\|\xi - \pi_{\mathbb{K}}(\xi)\big\|\big).$$

But this inequality shows that (6.7.1) holds, and this completes the proof. □

COROLLARY 6.8.1. *Let $\mathbb{K} \subseteq \mathbb{D} \subseteq \mathbb{R}^n$, with $\mathbb{K}$ locally closed and $\mathbb{D}$ open, and let $F : \mathbb{D} \rightsquigarrow \mathbb{R}^n$ be a multifunction. If F has the comparison property with respect to $(\mathbb{D}, \mathbb{K})$ and, for each $\xi \in \mathbb{K}$, $F(\xi) \subseteq \mathcal{T}_{\mathbb{K}}(\xi)$, then $\mathbb{K}$ is local invariant with respect to F.*

Corollary 6.8.1 and Proposition 6.2.1 yield:

COROLLARY 6.8.2. *Let $\mathbb{K} \subseteq \mathbb{D} \subseteq \mathbb{R}^n$, with $\mathbb{K}$ locally closed and $\mathbb{D}$ open, and let $F : \mathbb{D} \rightsquigarrow \mathbb{R}^n$ be l.s.c. with nonempty values. If, F has the comparison property with respect to $(\mathbb{D}, \mathbb{K})$ and, for each $\xi \in \mathbb{K}$, $F(\xi) \subseteq \mathcal{B}_{\mathbb{K}}(\xi)$, then $\mathbb{K}$ is local invariant with respect to F.*

7. Applications

7.1. *Invariance with respect to parametrized multifunctions*

Let us consider the parametrized multifunction $F : \mathbb{D} \rightsquigarrow \mathbb{R}^n$,

$$F(\xi) = \big\{f(\xi, v);\ v \in \mathbb{V}\big\},$$

where $\mathbb{D}$ is a nonempty and open subset in $\mathbb{R}^n$, $\mathbb{V}$ is a nonempty and compact subset in $\mathbb{R}^n$ and $f : \mathbb{D} \times \mathbb{R}^n \to \mathbb{R}^n$ is a continuous function. Let $\mathbb{K}$ be a locally closed subset of $\mathbb{D}$ and let us assume that F has convex values. We assume further that, for each measurable function $v : [0, a] \to \mathbb{V}$ and for each $\xi \in \mathbb{D}$, there exists $T \in (0, a]$ such that the equation $u'(t) = f(u(t), v(t))$ has a unique Carathéodory solution $u : [0, T] \to \mathbb{R}^n$ satisfying $u(0) = \xi$.

THEOREM 7.1.1. *Under the above circumstances, the following conditions are equivalent*:

(i) *for each $\xi \in \mathbb{K}$ and $v \in \mathbb{V}$, $f(\xi, v) \in \mathcal{C}_{\mathbb{K}}(\xi)$,*
(ii) *for each $\xi \in \mathbb{K}$ and $v \in \mathbb{V}$, $f(\xi, v) \in \mathcal{T}_{\mathbb{K}}(\xi)$,*

(iii) *for each* $\xi \in \mathbb{K}$ *and* $v \in \mathbb{V}$, $f(\xi, v) \in \mathcal{B}_{\mathbb{K}}(\xi)$,

(iv) $\mathbb{K}$ *is locally invariant with respect to* F.

In general, if $\mathcal{G} : \mathbb{K} \rightsquigarrow \mathbb{R}^n$ *is such that* $\mathcal{C}_{\mathbb{K}}(\xi) \subseteq \mathcal{G}(\xi) \subseteq \mathcal{B}_{\mathbb{K}}(\xi)$ *for each* $\xi \in \mathbb{K}$, *then each one of the conditions above is equivalent to*

(v) *for each* $\xi \in \mathbb{K}$, $f(\xi, v) \in \mathcal{G}(\xi)$.

PROOF. In view of Proposition 2.5.1, it suffices to show that (ii) is equivalent to (iv). Let us assume that (ii) holds true and let $u : [0, T] \to \mathbb{D}$ be a solution to $u'(t) \in F(u(t))$ with $u(0) = \xi \in \mathbb{K}$. We have to show that there exists $\tau \in (0, T]$ such that $u(t) \in \mathbb{K}$ for all $t \in [0, \tau]$. By a classical result of Filippov, there exists a measurable function $v : [0, T] \to \mathbb{V}$ such that

$$u'(t) = f\big(u(t), v(t)\big) \tag{7.1.1}$$

a.e. for $t \in [0, T]$. By the uniqueness property, taking into account (ii) and using Theorem 5.2.1, we deduce that there exists $\tau \in (0, T]$ such that the unique solution to (7.1.1) satisfies $u(t) \in \mathbb{K}$ for all $t \in [0, \tau]$. Thus (ii) implies (iv).

Let us suppose now that (iv) holds true. Fix $\xi \in \mathbb{K}$ and $v \in \mathbb{V}$. The equation $u'(t) = f(u(t), v)$ with $u(0) = \xi$ has a unique solution $u : [0, T] \to \mathbb{D}$. Since $\mathbb{K}$ is locally invariant with respect to F, there exists $\tau \in (0, T]$ such that we have $u(t) \in \mathbb{K}$ for all $t \in [0, \tau]$. As $u'(0) = f(\xi, v)$, it readily follows that $f(\xi, v) \in \mathcal{F}_{\mathbb{K}}(\xi) \subseteq \mathcal{T}_{\mathbb{K}}(\xi)$, and thus (iv) implies (ii). This completes the proof. □

7.2. *Differentiability along trajectories*

In this section we will show how viability can be used in order to obtain sufficient conditions for asymptotic stability via Liapunov functions. Let us consider the autonomous differential equation

$$u'(t) = g\big(u(t)\big), \tag{7.2.1}$$

where $g : \mathbb{R}^n \to \mathbb{R}^n$ is continuous. Let $V : \mathbb{R}^n \to \mathbb{R}$, and let us define

$$V^*(\xi) = \limsup_{h \downarrow 0} \frac{1}{h}\big[V\big(\xi + hg(\xi)\big) - V(\xi)\big]$$

and

$$V_*(\xi) = \liminf_{h \downarrow 0} \frac{1}{h}\big[V\big(\xi + hg(\xi)\big) - V(\xi)\big].$$

If $V^*(\xi) = V_*(\xi)$, we denote this common value by $\dot{V}(\xi)$ and we note that, if V is differentiable, we have $\dot{V}(\xi) = \langle \operatorname{grad} V(\xi), g(\xi)\rangle$. The next result will prove useful in the sequel.

THEOREM 7.2.1 (Yoshizawa [110]). *If* $V:\mathbb{R}^n \to \mathbb{R}$ *is locally Lipschitz,* $u:[0,T)\to\mathbb{R}^n$ *is any solution to* (7.2.1) *and* $t\in[0,T)$*, then*

$$V^*\big(u(t)\big) = \limsup_{h\downarrow 0}\frac{1}{h}\big[V\big(u(t+h)\big) - V\big(u(t)\big)\big].$$

PROOF. We have

$$\begin{aligned} V^*\big(u(t)\big) &= \limsup_{h\downarrow 0}\frac{1}{h}\big[V\big(u(t)\big) + hg\big(u(t)\big) - V\big(u(t)\big)\big] \\ &\leqslant \limsup_{h\downarrow 0}\frac{1}{h}\left[V\left(u(t) + \int_t^{t+h} g\big(u(s)\big)\,\mathrm{d}s\right) - V\big(u(t)\big)\right] \\ &\quad + \limsup_{h\downarrow 0}\frac{1}{h}\left[-V\left(u(t) + \int_t^{t+h} g\big(u(s)\big)\,\mathrm{d}s\right)\right. \\ &\quad \left. + V\big(u(t)\big) + hg\big(u(t)\big)\right]. \end{aligned}$$

Since

$$\begin{aligned} &\left|\limsup_{h\downarrow 0}\frac{1}{h}\left[-V\left(u(t) + \int_t^{t+h} g\big(u(s)\big)\,\mathrm{d}s\right) + V\big(u(t)\big) + hg\big(u(t)\big)\right]\right| \\ &\quad \leqslant L\limsup_{h\downarrow 0}\frac{1}{h}\left\|\int_t^{t+h} g\big(u(s)\big)\,\mathrm{d}s - hg\big(u(t)\big)\right\| = 0, \end{aligned}$$

where $L>0$ is the Lipschitz constant of V on a suitably chosen neighborhood of $u(t)$, we deduce

$$V^*\big(u(t)\big) \leqslant \limsup_{h\downarrow 0}\frac{1}{h}\big[V\big(u(t+h)\big) - V\big(u(t)\big)\big].$$

Similarly, we get

$$V^*\big(u(t)\big) \geqslant \limsup_{h\downarrow 0}\frac{1}{h}\big[V\big(u(t+h)\big) - V\big(u(t)\big)\big]$$

and this completes the proof. □

7.3. *Liapunov functions*

DEFINITION 7.3.1. We say that 0 is *stable* for (7.2.1) if for each $\varepsilon>0$ there exists $\delta(\varepsilon)\in(0,\varepsilon)$ such that for each $\xi\in\mathbb{R}^n$, $\|\xi\|\leqslant\delta(\varepsilon)$, each solution u of (7.2.1), satisfying $u(0)=\xi$, is defined on $[0,+\infty)$, and $\|u(t)\|\leqslant\varepsilon$ for all $t\geqslant 0$.

Clearly, if 0 is stable for (7.2.1), $\{0\}$ is both viable and locally invariant with respect to g, and thus $g(0) = 0$. In other words, if 0 is stable for (7.2.1), then $u \equiv 0$ is necessarily a solution to (7.2.1), and this is the only one issuing from 0.

DEFINITION 7.3.2. We say that V has positive gradient at $v \in \mathbb{R}$ if

$$\liminf_{\substack{\operatorname{dist}(\xi;\mathbb{K})\downarrow 0\\ \xi\notin\mathbb{K}}} \frac{V(\xi)-v}{\operatorname{dist}(\xi;\mathbb{K})} > 0,$$

where $\mathbb{K} = V^{-1}((-\infty, v])$.

If V is of class C^1 and $\|\operatorname{grad} V\|$ is bounded from below on $V^{-1}(\{v\})$ by a constant $c > 0$, then V has positive gradient at v.

PROPOSITION 7.3.1. *Let* $g : \mathbb{R}^n \to \mathbb{R}^n$ *and* $V : \mathbb{R}^n \to \mathbb{R}$ *be continuous, and let* $\mathbb{K} = V^{-1}((-\infty, v])$. *If* V *has positive gradient at* v *and* $V^*(\xi) \leqslant 0$ *whenever* $V(\xi) = v$, *then* $\mathbb{K}$ *is viable with respect to* g.

PROOF. Let us assume by contradiction that $\mathbb{K}$ is not viable with respect to g. In view of Theorem 3.1.1, this means that there exists $\xi \in \partial\mathbb{K}$ such that $g(\xi)$ is not tangent in the sense of Federer to $\mathbb{K}$ at ξ. So, there exist $\gamma > 0$ and a sequence $h_m \downarrow 0$ such that

$$\gamma < \frac{1}{h_m}\operatorname{dist}\bigl(\xi + h_m g(\xi); \mathbb{K}\bigr)$$

for all $m \in \mathbb{N}$. As $\xi \in \partial\mathbb{K}$, it follows that $V(\xi) = v$. Furthermore, since V has positive gradient at v, there exists $\nu > 0$ such that

$$\nu < \frac{V(\xi + h_m g(\xi)) - v}{\operatorname{dist}(\xi + h_m g(\xi); \mathbb{K})} < \frac{1}{h_m\gamma}\bigl[V\bigl(\xi + h_m g(\xi)\bigr) - v\bigr]$$

for each $m \in \mathbb{N}$. Hence

$$0 < \nu \leqslant \frac{1}{\gamma}\limsup_{h\downarrow 0}\frac{V(\xi + hg(\xi)) - V(\xi)}{h} = \frac{1}{\gamma}V^*(\xi),$$

thereby contradicting the hypothesis that $V^*(\xi) \leqslant 0$. This contradiction can be eliminated only if $\mathbb{K}$ is viable with respect to g, and this completes the proof. □

THEOREM 7.3.1 (Yorke [108]). *Assume that* (7.2.1) *has the uniqueness property. Then* 0 *is stable for* (7.2.1) *if and only if there exist a continuous function* $V : \mathbb{R}^n \to [0, +\infty)$ *and a sequence* $v_m \downarrow 0$ *such that* $V(x) = 0$ *if and only if* $x = 0$, *and, for every* $m \in \mathbb{N}$ *for which* $V(x) = v_m$, *we have* $V^*(x) \leqslant 0$, *and, for each* $m \in \mathbb{N}$, V *has positive gradient at* v_m.

PROOF. We denote by $u(\cdot,\xi):[0,+\infty)\to\mathbb{R}^n$ the unique solution of (7.2.1) satisfying $u(0,\xi)=\xi$.

Sufficiency. Let us assume that such a sequence $(v_m)_m$ and function V exist. Let $\mathbb{K}_m = V^{-1}([0,v_m])$. Since (7.2.1) has the uniqueness property, by Proposition 7.3.1, it follows that $\mathbb{K}_m$ is both viable and locally invariant with respect to g. Let $\varepsilon>0$ and let us define both $\mu_*(\varepsilon)=\inf_{\|\xi\|=\varepsilon} V(\xi)$ and $\mu^*(\varepsilon)=\sup_{\|\xi\|=\varepsilon} V(\xi)$. Then, $\mu_*(\varepsilon)>0$. For any $\varepsilon>0$, choose $m=m(\varepsilon)$ such that $v_m<\mu_*(\varepsilon)$, and choose $\delta(\varepsilon)\in(0,\varepsilon)$ such that $\mu^*(\delta)<v_m$ for each $\delta\in(0,\delta(\varepsilon))$. Let $\xi\in\mathbb{R}^n$ with $\|\xi\|\leqslant\delta(\varepsilon)$. Clearly, $\xi\in\mathbb{K}_m$. If there exists $t>0$ such that $\|u(t,\xi)\|>\varepsilon$, then there exists $t_0\in(0,t)$ such that $\|u(t_0,\xi)\|=\varepsilon$. On the other hand, by the choice of m, we have $u(t_0,\xi)\notin\mathbb{K}_m$, thereby contradicting the local invariance of $\mathbb{K}_m$ with respect to g. This contradiction can be eliminated only if $\|u(t,\xi)\|<\varepsilon$ for all $t\geqslant 0$, and this completes the proof of the sufficiency.

Necessity. Suppose that 0 is stable for (7.2.1). Let $\delta(\cdot)$ the function in Definition 7.3.1, choose $\varepsilon_1>0$, and let us define inductively $\varepsilon_{m+1}=\delta(\varepsilon_m)/2$. Clearly, $\varepsilon_m\downarrow 0$. Let us denote by

$$\mathbb{K}_m^0=\bigl\{u(t,\xi);\ \|\xi\|\leqslant\delta(\varepsilon_m),\ \text{and } t\geqslant 0\bigr\}.$$

Since $\mathbb{K}_m^0$ contains only points reached at positive time by solutions starting in $B(0,\delta(\varepsilon_m))$, it follows that $\mathbb{K}_m^0$ is viable with respect to g. By Proposition 3.6.1, we deduce that $\mathbb{K}_m=\overline{\mathbb{K}_m^0}$ is viable with respect to g. Since $u'(t)=g(u(t))$ has the uniqueness property, it follows that $\mathbb{K}_m$ is in fact invariant with respect to g. For each $m=1,2,\ldots,$ let

$$v_m=\sum_{i=m+1}^{\infty}\varepsilon_i.$$

Clearly, $v_m=\frac{1}{2}\sum_{i=m+1}^{\infty}\delta(\varepsilon_{i-1})\leqslant\varepsilon_m$ for $m=1,2,\ldots$. Let $\mathbb{K}_0=\mathbb{R}^n$ and $v_0=+\infty$. We have $\cdots\subseteq\mathbb{K}_2\subseteq\mathbb{K}_1\subseteq\mathbb{K}_0$ and therefore, we may define $N(\xi)=\max\{m;\ \xi\in\mathbb{K}_m\}$. Notice that we want to have $V(\xi)=v_m$ for all $\xi\in\partial\mathbb{K}_m$. Define $V(0)=0$ and

$$V(\xi)=\min\bigl\{v_{N(\xi)},v_{N(\xi)+1}+\operatorname{dist}(\xi;\mathbb{K}_{N(\xi)+1})\bigr\}$$

for $\xi\neq 0$. We begin by proving that V is continuous. First, let us observe that, for each $m\in\mathbb{N}$, the function N is constant on $\mathbb{K}_m\setminus\mathbb{K}_{m+1}$. Accordingly the restriction of V to $\mathbb{K}_m\setminus\mathbb{K}_{m+1}$ is continuous, and so the function V itself is continuous at each interior point of $\mathbb{K}_m\setminus\mathbb{K}_{m+1}$. Next, we show that V is continuous on $\partial\mathbb{K}_m$ for each $m\in\mathbb{N}$. Let ξ be arbitrary in $\partial\mathbb{K}_m$. We have both $\|\xi\|\in[\delta(\varepsilon_m),\varepsilon_m)$ and $\sup_{\eta\in\mathbb{K}_{m+1}}\|\eta\|\leqslant\varepsilon_{m+1}$. Therefore, $N(\xi)=m$ and $\operatorname{dist}(\xi;\mathbb{K}_{m+1})>\delta(\varepsilon_m)-\varepsilon_{m+1}=\delta(\varepsilon_m)/2$. Hence we have $v_{N(\xi)+1}+\operatorname{dist}(\xi;\mathbb{K}_{N(\xi)+1})>v_{N(\xi)}$ and $V(\xi)=v_m$. Choose $\xi_i\notin\mathbb{K}_m$ for $i=1,2,\ldots,$ with $\xi_i\to\xi$. Then, $\lim_{i\to\infty}\operatorname{dist}(\xi_i;\mathbb{K}_m)=0$, and

$$\lim_{i\to\infty}V(\xi_i)=v_m=V(\xi),$$

which shows that V is continuous at ξ. It remains to prove that V is continuous at 0. Take $\xi_i \to 0$. Then $N(\xi_i) \to \infty$ and $V(\xi_i) \leqslant v_{N(\xi_i)}$. But $v_m \to 0$ as $m \to \infty$, so that

$$\lim_{\xi \to 0} V(\xi) = 0 = V(0).$$

Thus V is continuous on $\mathbb{R}^n$.

Finally, we show that $V(\xi) = v_m$ implies $V^*(\xi) \leqslant 0$. Indeed, if for some $m \in \mathbb{N}$ we have $V(\xi) = v_m$, then $\xi \in \mathbb{K}_m$, $\xi + hg(\xi) \in \mathbb{K}_{m-1}$ for $h > 0$ sufficiently small, and

$$V\big(\xi + hg(\xi)\big) \leqslant v_m + \operatorname{dist}\big(\xi + hg(\xi); \mathbb{K}_m\big).$$

Since $\mathbb{K}_m$ is viable with respect to g, by virtue of Theorem 3.2.1, we have $g(\xi) \in \mathcal{T}_{\mathbb{K}_m}(\xi)$, and therefore

$$V^*(\xi) \leqslant \limsup_{h \downarrow 0} \frac{1}{h} \operatorname{dist}\big(\xi + hg(\xi); \mathbb{K}_m\big) = 0.$$

If $0 < \operatorname{dist}(\xi; \mathbb{K}_m) \leqslant v_m - v_{m-1} = \varepsilon_m$, then $V(\xi) = v_m + \operatorname{dist}(\xi; \mathbb{K}_m)$, so that V has positive gradient at each v_m, thereby completing the proof. □

7.4. *Hukuhara's theorem*

In this section, by using viability and invariance techniques, we will prove two celebrated results concerning the funnel of solutions, results due to Hukuhara [47] and Kneser [61]. Let $f : \mathbb{I} \times \mathbb{D} \to \mathbb{R}^n$ be a continuous function, and let us consider the non-autonomous differential equation (1.1.1). Let $(\tau, \xi) \in \mathbb{I} \times \mathbb{D}$, and let us denote by $\mathcal{S}(\tau, \xi)$ the set of all noncontinuable solutions u of (1.1.1) satisfying $u(\tau) = \xi$.

DEFINITION 7.4.1. The *right solution funnel* through $(\tau, \xi) \in \mathbb{I} \times \mathbb{D}$, $F_{\tau,\xi}$, is defined by

$$F_{\tau,\xi} = \big\{\big(s, u(s)\big);\ s \geqslant \tau,\ u \in \mathcal{S}(\tau, \xi)\big\}.$$

If $t \geqslant \tau$, we define the *t-cross section of* $F_{\tau,\xi}$ by

$$F_{\tau,\xi}(t) = \big\{u(t);\ u \in \mathcal{S}(\tau, \xi)\big\}.$$

The next compactness result will prove useful in that follows.

PROPOSITION 7.4.1. *Let $(\tau, \xi) \in \mathbb{I} \times \mathbb{D}$ and let $t > \tau$ be such that, for each $u \in \mathcal{S}(\tau, \xi)$, $u(t)$ is defined. Then*

$$F_{\tau,\xi}\big([\tau, t]\big) = \big\{\big(s, u(s)\big);\ s \in [\tau, t],\ u \in \mathcal{S}(\tau, \xi)\big\}$$

is compact.

PROOF. Let $(t_m, u_m(t_m))_m$ be an arbitrary sequence in $F_{\tau,\xi}([\tau,t])$, with $u_m : (a_m, b_m) \to \mathbb{D}$ for each $m \in \mathbb{N}$. We may assume with no loss of generality that $\lim_m t_m = s$. Obviously, $s \in [\tau, t] \subseteq (a_m, b_m)$ for every $m \in \mathbb{N}$, and therefore, by Hartman [54, Theorem 3.2, p. 26], there exists at least one subsequence of $(u_m)_m$, denoted for simplicity again by $(u_m)_m$, and $u \in \mathcal{S}(\tau,\xi)$, with $\lim_m u_m = u$ uniformly on $[\tau, t]$. But this shows that $\lim_m (t_m, u_m(t_m)) = (s, u(s))$. Since $(s, u(s)) \in F_{\tau,\xi}([\tau, t])$, the proof is complete. □

From Proposition 7.4.1, we deduce:

COROLLARY 7.4.1. *The set $F_{\tau,\xi}$ is locally closed.*

THEOREM 7.4.1 (Hukuhara [47]). *Let $(\tau,\xi) \in \mathbb{I} \times \mathbb{D}$ and let $t > \tau$ be such that, for each $u \in \mathcal{S}(\tau,\xi)$, $u(t)$ is defined. Then, for each $\eta \in \partial F_{\tau,\xi}(t)$ there exists a solution v such that $v(s) \in \partial F_{\tau,\xi}(s)$ for all $s \in [\tau, t]$.*

In order to prove Theorem 7.4.1, we need:

THEOREM 7.4.2 (Yorke [108]). *If $\mathbb{D}$ is a domain, $\mathbb{K}_1, \mathbb{K}_2 \subseteq \mathbb{D}$ are locally closed and viable with respect to f, and if $\mathbb{K}_1 \cup \mathbb{K}_2 = \mathbb{D}$, then $\mathbb{K}_1 \cap \mathbb{K}_2$ is viable with respect to f.*

PROOF. The conclusion is a consequence of Theorem 2.3.1 and Nagumo's viability theorem 3.1.1. □

REMARK 7.4.1. A result similar to Theorem 7.4.2 holds true trivially in the case of local invariance. More precisely, if $\mathbb{D} \subseteq \mathbb{R}^n$ is open, $\mathbb{K}_1, \mathbb{K}_2 \subseteq \mathbb{D}$ are locally closed and locally invariant with respect to f, then $\mathbb{K}_1 \cap \mathbb{K}_2$ is locally invariant with respect to f.

Let $\tau \in \mathbb{I}$ be fixed, let us denote by $\mathcal{D} = \{s \in \mathbb{I};\ s > \tau\} \times \mathbb{D}$, and let us define $\mathcal{F} : \mathcal{D} \to \mathbb{R} \times \mathbb{R}^n$, by $\mathcal{F}(t,\xi) = (1, f(t,\xi))$ for each $(t,\xi) \in \mathcal{D}$. Throughout, we denote by $\partial_{\mathcal{D}} F_{\tau,\xi}$ the boundary of $F_{\tau,\xi}$ relative to $\mathcal{D}$, i.e. $\partial_{\mathcal{D}} F_{\tau,\xi} = \overline{(\mathcal{D} \setminus F_{\tau,\xi})}^{\mathcal{D}} \cap \overline{\mathcal{D} \cap F_{\tau,\xi}}^{\mathcal{D}}$. We will deduce Theorem 7.4.1 from a slightly more general result, i.e. Theorem 7.4.3 below.

THEOREM 7.4.3 (Yorke [108]). *For each $(\tau,\xi) \in \mathbb{I} \times \mathbb{D}$, the set $\partial_{\mathcal{D}} F_{\tau,\xi}$ is left viable with respect to $\mathcal{F}$.*

PROOF. Let us observe that (1.1.1) can be equivalently written as

$$w'(t) = \mathcal{F}\big(w(t)\big),$$

where $\mathcal{F}$ is defined as above, and $w = (s, u)$. By the definition of $F_{\tau,\xi}$, we easily deduce that $\mathcal{D} \cap F_{\tau,\xi}$ is right viable and right locally invariant with respect to $\mathcal{F}$, and hence, by Propositions 1.1.1–1.1.3, it follows that $\mathcal{D} \setminus F_{\tau,\xi}$ is both left viable and left locally invariant with respect to $\mathcal{F}$. So, thanks to Proposition 3.6.1, we conclude that $\mathcal{K}_1 = \overline{\mathcal{D} \setminus F_{\tau,\xi}}^{\mathcal{D}}$ is left viable with respect to $\mathcal{F}$. Further, also by definition, $\mathcal{D} \cap F_{\tau,\xi}$ is left viable with respect to $\mathcal{F}$, and again by Proposition 3.6.1, it follows that $\mathcal{K}_2 = \overline{\mathcal{D} \cap F_{\tau,\xi}}^{\mathcal{D}}$ is left viable with respect to $\mathcal{F}$. Since $\mathcal{K}_1 \cup \mathcal{K}_2 = \mathcal{D}$, by Remark 1.1.1 and Theorem 7.4.2, we conclude that $\mathcal{K}_1 \cap \mathcal{K}_2 = \partial_{\mathcal{D}} F_{\tau,\xi}$ is left viable with respect to $\mathcal{F}$, and this completes the proof. □

We may now proceed to the proof of Theorem 7.4.1.

PROOF OF THEOREM 7.4.1. First, let us observe that thanks to Proposition 7.4.1, it follows that $\partial_{\mathcal{D}} F_{\tau,\xi} \subseteq F_{\tau,\xi}$. Hence, in view of Theorem 7.4.3, we know that, for each $(t, u(t)) \in \partial_{\mathcal{D}} F_{\tau,\xi}$, there exists at least one solution $v : [\theta, t] \to \mathbb{D}$, with $\tau \leqslant \theta < t$, $v(t) = u(t)$ and such that $(s, v(s)) \in \partial_{\mathcal{D}} F_{\tau,\xi}(s)$ for each $s \in [\theta, t]$. But, by virtue of Proposition 7.4.1, $F_{\tau,\xi}([\tau, t])$ is compact, and therefore a simple maximality argument shows that we can always extend such a solution to $[\tau, t]$, and this achieves the proof. □

REMARK 7.4.2. Theorem 7.4.3 implies that, for each $(\tilde{t}, \tilde{y}) \in \partial_{\mathcal{D}} F_{\tau,\xi}$, there exists at least one noncontinuable solution, $v(\cdot) : (\sigma, \tilde{t}] \to \mathbb{R}^n$, of (1.1.1), such that $(s, v(s)) \in \partial_{\mathcal{D}} F_{\tau,\xi}$ for all $s \in (\sigma, \tilde{t}] \cap [\tau, \tilde{t}]$. If $t > \tau$ is chosen as in Theorem 7.4.1 and $\tilde{t} \in [\tau, t]$, then by virtue of both Theorem 7.4.3 and Proposition 7.4.1, it follows that $[\tau, \tilde{t}] \subset (\sigma, \tilde{t}]$.

REMARK 7.4.3. We notice that

$$\partial F_{\tau,\xi}(t) \subseteq (\partial_{\mathcal{D}} F_{\tau,\xi})(t) = \left\{ v \in \mathbb{R}^n;\ (t, v) \in \partial_{\mathcal{D}} F_{\tau,\xi} \right\}$$

and the inclusion can be strict. So, Theorem 7.4.3 is more general that Theorem 7.4.1 because it considers all of $\partial_{\mathcal{D}} F_{\tau,\xi}$.

7.5. *Kneser's theorem*

We conclude this section with the celebrated theorem of Kneser.

THEOREM 7.5.1 (Kneser [61]). *Let $(\tau, \xi) \in \mathbb{I} \times \mathbb{D}$ and let $t > \tau$ be such that, for each $u \in \mathcal{S}(\tau, \xi)$, $u(t)$ is defined. Then $F_{\tau,\xi}(t)$ is connected.*

PROOF. Let us assume by contradiction that $F_{\tau,\xi}(t)$ is not connected. Then there exist two nonempty subsets $\mathbb{C}_1$, $\mathbb{C}_2$ with $F_{\tau,\xi}(t) = \mathbb{C}_1 \cup \mathbb{C}_2$ but $\mathbb{C}_1 \cap \overline{\mathbb{C}_2} = \overline{\mathbb{C}_1} \cap \mathbb{C}_2 = \emptyset$. Let $\mathbb{K}_1$ be the union of all right noncontinuable trajectories[4] of (1.1.1) whose corresponding solutions v, either are not defined at t, or, if defined, satisfy

$$\operatorname{dist}\big(v(t); \mathbb{C}_1\big) \leqslant \operatorname{dist}\big(v(t); \mathbb{C}_2\big). \tag{7.5.1}$$

Similarly, we define $\mathbb{K}_2$ by reversing the inequality (7.5.1). By virtue of Proposition 1.1.1, both $\mathbb{K}_1$ and $\mathbb{K}_2$ are right viable with respect to $\mathcal{F}$. In addition, $\mathbb{K}_1$ and $\mathbb{K}_2$ are locally closed in $\mathbb{I} \times \mathbb{D}$ and $\mathbb{K}_1 \cup \mathbb{K}_2 = \mathbb{I} \times \mathbb{D}$. So, by Proposition 3.6.1, it follows that both $\overline{\mathbb{K}_1}^{\mathcal{D}}$ and $\overline{\mathbb{K}_2}^{\mathcal{D}}$ are right viable with respect to $\mathcal{F}$ and, of course, locally closed. In view of Theorem 7.4.2, we conclude that $\mathbb{K} = \overline{\mathbb{K}}_1^{\mathcal{D}} \cap \overline{\mathbb{K}}_2^{\mathcal{D}}$ is right viable with respect to $\mathcal{F}$. As $(\tau, \xi) \in \mathbb{K}$, there exists a noncontinuable solution v such that $(s, v(s)) \in \mathbb{K}$ for each s in the domain of v. By the choice of t, $v(t)$ is defined and belongs to $\mathbb{C}_1 \cup \mathbb{C}_2$. Since $(t, v(t)) \in \mathbb{K}$, $\operatorname{dist}(v(t); \mathbb{C}_1) = \operatorname{dist}(v(t); \mathbb{C}_2)$ which must be 0. But this is absurd because $v(t)$ would be either in $\mathbb{C}_1 \cap \overline{\mathbb{C}}_2$, or in $\overline{\mathbb{C}}_1 \cap \mathbb{C}_2$. This contradiction can be eliminated only if $F_{\tau,\xi}(t)$ is connected as claimed. □

---

[4] We recall that a trajectory of (1.1.1) is a set of the form $\{v(t);\ t \in \mathbb{I}_v\}$, where $v : \mathbb{I}_v \to \mathbb{D}$ is a solution of (1.1.1).

7.6. *The characteristics method for a first order PDE*

Let Ω be a nonempty open subset of $\mathbb{R}^n$, let $H : \Omega \times \mathbb{R} \rightsquigarrow \mathbb{R}^n \times \mathbb{R}$ be a multifunction with nonempty values, and consider the first order partial differential equation

$$\inf_{(u,v)\in H(x,w(x))} \big(Dw(x)(u) - v\big) = 0, \tag{7.6.1}$$

where D denotes the differentiability concept of Severi [90]. We recall that a function $w : \Omega \to \mathbb{R}$ is *Severi differentiable* at a point $x \in \Omega$ if, for every $u \in \mathbb{R}^n$, there exists the finite limit

$$Dw(x)(u) = \lim_{\substack{s\downarrow 0\\ p\to 0}} \left(\frac{1}{s}\right)\big(w\big(x + s(u+p)\big) - w(x)\big),$$

called the *Severi differential of* w *at* x *in the direction* u. If w is Severi differentiable at x, the function $u \mapsto Dw(x)(u)$ from $\mathbb{R}^n$ to $\mathbb{R}$ is the *Severi differential of* w *at* x. For details see Ursescu [94]. We have

$$\operatorname{graph}\big(Dw(x)\big) = \mathcal{T}_{\operatorname{graph}(w)}\big(x, w(x)\big).$$

For $u \in \mathbb{R}^n$, let us consider the extended real numbers:

$$\underline{D}w(x)(u) = \liminf_{\substack{s\downarrow 0\\ p\to 0}} \left(\frac{1}{s}\right)\big(w\big(x + s(u+p)\big) - w(x)\big),$$

$$\overline{D}w(x)(u) = \limsup_{\substack{s\downarrow 0\\ p\to 0}} \left(\frac{1}{s}\right)\big(w\big(x + s(u+p)\big) - w(x)\big).$$

We have the equalities:

$$\operatorname{epi}\big(\underline{D}w(x)\big) = \mathcal{T}_{\operatorname{epi}(w)}\big(x, w(x)\big),$$

$$\operatorname{hyp}\big(\overline{D}w(x)\big) = \mathcal{T}_{\operatorname{hyp}(w)}\big(x, w(x)\big),$$

where epi stands for the epigraph and hyp for the hypograph. To conclude, w is differentiable at x if and only if $\underline{D}w(x)(u)$ and $\overline{D}w(x)(u)$ are finite and equal to each other for all $u \in \mathbb{R}^n$, while $\overline{D}w(x)(u) \leqslant \underline{D}w(x)(u)$ for all $u \in \mathbb{R}^n$.

The epigraph and hypograph equalities above show that $u \mapsto \underline{D}w(x)(u)$ and $u \mapsto \overline{D}w(x)(u)$ are l.s.c. and u.s.c., respectively.

By a solution to Eq. (7.6.1) we mean a differentiable function $w : \Omega \to \mathbb{R}$ which satisfies equality (7.6.1) for all $x \in \Omega$. Equation (7.6.1) is worth noting since it contains at least two important particular cases: the quasilinear, first order partial differential equations (Goursat [51], Perron [81], Kamke [59], Carathéodory [29], Courant and Hilbert [37]); the Bellman equations (Bellman [7–9], Pontryagin et al. [83], Boltyanskii [11,12], Gonzales [50], Hájek [53], Cesari [30], Clarke and Vinter [35], and many others). Among other particular cases of Eq. (7.6.1) we mention also the eikonal equation (see Ishii [58]). Let us consider further the ordinary differential inclusion

$$\bigl(X'(t), Y'(t)\bigr) \in H\bigl(X(t), Y(t)\bigr), \tag{7.6.2}$$

whose solutions we label as characteristics with regard to Eq. (7.6.1). The theory for the inclusion (7.6.2) is well developed (see Section 6.1 above) and we use it to start developing an existence theory for Eq. (7.6.1). We take here as a model the classical characteristics method and characterize the solutions w of (7.6.1) by means of the behavior of the functions w along solutions (X, Y) of (7.6.2). Since the inclusion (7.6.2) is an autonomous one, we consider only solutions $(X, Y) : [0, T) \to \mathbb{R}^n \times \mathbb{R}$ where $0 < T \leqslant \infty$. In order to characterize the solutions w of (7.6.1), we need the following conditions:

- (C_1) *For every $x \in \Omega$, there exists a solution $(X, Y) : [0, T) \to \mathbb{R}^n \times \mathbb{R}$ of the inclusion* (7.6.2)*, with $(X(0), Y(0)) = (x, w(x))$, such that, for every $s \in (0, T)$, $w(X(s)) \leqslant Y(s)$;*
- (C_2) *For every $x \in \Omega$, for every solution $(X, Y) : [0, T) \to \mathbb{R}^n \times \mathbb{R}$ of the inclusion* (7.6.2)*, with $(X(0), Y(0)) = (x, w(x))$, and for every $s \in (0, T)$, $Y(s) \leqslant w(X(s))$.*

Now we are ready to state a first result concerning Eq. (7.6.1).

THEOREM 7.6.1. *Let $H : \Omega \times \mathbb{R} \rightsquigarrow \mathbb{R}^n \times \mathbb{R}$ be both u.s.c. and l.s.c. with nonempty, compact and convex values, and let $w : \Omega \to \mathbb{R}$ be differentiable and such that H has the comparison property with respect to* $(\Omega \times \mathbb{R}, \operatorname{hyp}(w))$. *Then w is a solution to Eq.* (7.6.1) *if and only if it satisfies conditions* (C_1) *and* (C_2).

As far as we know, the differentiability concept of Severi is the least restrictive for which the characterization above holds true. Every other differentiability concepts used in the literature devoted to particular cases of Eq. (7.6.1) implies the classical Fréchet, referred better as to Stolz–Young–Fréchet–Hadamard, differentiability. And, w is Fréchet differentiable at x if and only if both w is Severi differentiable at x, and the Severi differential $Dw(x)$ is linear on $\mathbb{R}^n$. In addition, Eq. (7.6.1) admits a natural substitute which dispenses with any differentiability restriction, and which can be still characterized by using (C_1)

and (C$_2$). The substitute for Eq. (7.6.1) consists of the couple of first order partial differential inequalities below:

$$\inf_{(u,v)\in H(x,w(x))}\bigl(\underline{D}w(x)(u)-v\bigr)\leqslant 0, \tag{7.6.3}$$

$$0\leqslant \inf_{(u,v)\in H(x,w(x))}\bigl(\overline{D}w(x)(u)-v\bigr), \tag{7.6.4}$$

called *generalized Bellman equation*. A *solution to inequality* (7.6.3) (or (7.6.4)) is a function $w:\Omega\to\mathbb{R}$ which satisfies inequality (7.6.3) (or (7.6.4)) for all $x\in\Omega$. Clearly a function w is a solution to (7.6.1) if and only if it is a differentiable solution to the couple (7.6.3) and (7.6.4). Since differentiability at a point implies continuity at that point, we conclude that Theorem 7.6.1 above is a natural corollary of Theorem 7.6.2 below.

THEOREM 7.6.2. *Let $H:\Omega\times\mathbb{R}\rightsquigarrow\mathbb{R}^n\times\mathbb{R}$ be both u.s.c. and l.s.c. with nonempty, compact and convex values, and let $w:\Omega\to\mathbb{R}$ be continuous such that H has the comparison property with respect to $(\Omega\times\mathbb{R},\operatorname{hyp}(w))$. Then, w is a solution to* (7.6.3) *and* (7.6.4) *if and only if it satisfies conditions* (C$_1$) *and* (C$_2$).

We mention that all solutions to every variational problem satisfy both (C$_1$) and (C$_2$) (the Bellman "principle") with a suitable chosen H. Hence, under rather common hypotheses upon the components of a variational problem, its continuous solution satisfies inequalities (7.6.3) and (7.6.4) (the generalized Bellman "equation"). A typical example is the time optimal control problem associated to a control system and a target. More precisely, consider the multifunction $F:\mathbb{R}^n\rightsquigarrow\mathbb{R}^n$, the differential inclusion

$$X'(t)\in F\bigl(X(t)\bigr), \tag{7.6.5}$$

and fix a *target set* $\mathcal{T}$ (nonempty and closed). Let $\mathcal{R}$ be the *reachable set*, that is, the set of all initial points which can be transferred to $\mathcal{T}$ by trajectories of (7.6.5). For $x\in\mathcal{R}$ define $T(x)$ as the infimum of the transition times. The well-known Bellman equation for the optimal time problem is

$$-1+\sup_{u\in F(x)}-DT(x)(u)=0,\qquad x\in\mathcal{R}\setminus\mathcal{T},$$

which is a particular case of (7.6.1), for the choice $H(x,y)=(F(x),\{-1\})$.

In its turn, Theorem 7.6.2 follows from the following anatomized variant of itself.

THEOREM 7.6.3. (a) *Let $H:\Omega\times\mathbb{R}\rightsquigarrow\mathbb{R}^n\times\mathbb{R}$ be u.s.c. with nonempty, compact and convex values. A continuous function $w:\Omega\to\mathbb{R}$ is a solution to inequality* (7.6.3) *if and only if satisfies condition* (C$_1$).

(b) *Let $H:\Omega\times\mathbb{R}\rightsquigarrow\mathbb{R}^n\times\mathbb{R}$ be l.s.c. with closed and convex values. Let $w:\Omega\to\mathbb{R}$ be a continuous function such that H has the comparison property with respect to $(\Omega\times\mathbb{R},\operatorname{hyp}(w))$. Then w is a solution to inequality* (7.6.4) *if and only if it satisfies condition* (C$_2$).

PROOF. (a) Since $H(x, w(x))$ is compact and since $\underline{D}w(x)$ is l.s.c. on $\mathbb{R}^n$, it follows that "inf" can be replaced by "min" in (7.6.3), hence inequality (7.6.3) states that

$$\phi \neq H\big(x, w(x)\big) \cap \mathcal{T}_{\mathrm{epi}(w)}\big(x, w(x)\big). \tag{7.6.6}$$

Since w is continuous, (7.6.6) is equivalent to (7.6.7) below

$$\phi \neq H(x, t) \cap \mathcal{T}_{\mathrm{epi}(w)}(x, t) \tag{7.6.7}$$

for $t \geqslant w(x)$, and this simply because $\mathcal{T}_{\mathrm{epi}(w)}(x, t) = \mathbb{R}^n \times \mathbb{R}$ whenever $w(x) < t$. On the other hand, since w is continuous, condition (C_1) is equivalent to the viability of epi(w) with respect to H. But the set epi(w) is closed in $\Omega \times \mathbb{R}$, and therefore the conclusion is an immediate consequence of Theorem 6.2.1.

(b) The inequality in (7.6.4) states that $H(x, w(x)) \subseteq \mathcal{T}_{\mathrm{hyp}(w)}(x, w(x))$. Since w is continuous, we have $H(x, t) \subseteq \mathcal{T}_{\mathrm{hyp}(w)}(x, t)$ in case $w(x) > t$. On the other hand, condition (C_2) states that the set hyp(w) is invariant with respect to H. Since the set hyp(w) is closed in $\Omega \times \mathbb{R}$, the conclusion follows from Theorem 6.8.1 and Corollary 6.8.1. □

A natural question is whether we can weaken the continuity property of the function w in Theorem 7.6.2. This question arises from the fact that epi(w) is closed even in the case when w is l.s.c. and hyp(w) is closed in case w is u.s.c. The answer is in the negative as the following examples in Cârjă and Ursescu [25] show. Consider first the inequality

$$\underline{D}w(x)\big(w(x)\big) - 1 \leqslant 0.$$

Here $H(x, y) = \{(y, 1)\}$, for all $(x, y) \in \mathbb{R} \times \mathbb{R}$ and the characteristic system $X'(s) = Y(s)$, $Y'(s) = 1$ has the solution $X(s) = X(0) + sY(0) + s^2/2$, $Y(s) = Y(0) + s$. The l.s.c. function $w : \mathbb{R} \to \mathbb{R}$ given by $w(x) = 0$ for $x = 0$ and by $w(x) = 1$ for $x \neq 0$ is a solution to the preceding inequality but does not satisfy the condition: *for every* $x \in \mathbb{R}$ *and for every* $s \in (0, +\infty)$, $w(x + sw(x) + s^2/2) \leqslant w(x) + s$ (take $x = 0$ and $s \in (0, 1)$ and observe $w(0 + sw(0) + s^2/2) = 1 > s = w(0) + s$). A second example is given by the differential inequality

$$0 \leqslant \overline{D}w(x)\big(w(x)\big) + 1.$$

Here $H(x, y) = \{(y, -1)\}$ for all $(x, y) \in \mathbb{R} \times \mathbb{R}$ and the characteristic system $X'(s) = Y(s)$, $Y'(s) = -1$ has the solutions $X(s) = X(0) + sy(0) - s^2/2$, $Y(s) = Y(0) - s$. The u.s.c. function $w : \mathbb{R} \to \mathbb{R}$ given by $w(x) = 0$ for $x = 0$ and by $w(x) = -1$ for $x \neq 0$ is a solution to the preceding inequality but does not satisfy the condition: *for every* $x \in \mathbb{R}$ *and for every* $s \in (0, +\infty)$, $w(x) - s \leqslant w(x + sw(x) - s^2/2)$ (take $x = 0$ and $s \in (0, 1)$ and observe $w(0) - s = -s > -1 = w(0) + sw(0) - s^2/2)$.

A condition which assures that (C_1) in part (a) of Theorem 7.6.3 holds for a l.s.c. function w, while (C_2) in part (b) holds for a u.s.c. function w is given below:

THEOREM 7.6.4. *Let $H : \Omega \times \mathbb{R} \rightsquigarrow \mathbb{R}^n \times \mathbb{R}$ be a nonempty and convex valued multifunction satisfying*

$$H(x, y_1) \subseteq H(x, y_2) \tag{7.6.8}$$

for each $x \in \Omega$ and $y_1, y_2 \in \mathbb{R}$, with $y_1 \leqslant y_2$. (a) *Assume that H is u.s.c. with compact values. Then, a l.s.c. function $w : \Omega \to \mathbb{R}$ is a solution to the inequality* (7.6.3) *if and only if it satisfies* (C_1).

(b) *Assume that H is l.s.c. with closed values. Let $w : \Omega \to \mathbb{R}$ a u.s.c. function such that H has the comparison property with respect to $(\Omega \times \mathbb{R}, \mathrm{hyp}(w))$. Then, $w : \Omega \to \mathbb{R}$ is a solution to the inequality* (7.6.4) *if and only if it satisfies* (C_2).

PROOF. The proof goes in the same spirit as that of Theorem 7.6.3. Indeed, in order to prove (a), since $\mathcal{T}_{\mathrm{epi}(w)}(x, w(x)) \subseteq \mathcal{T}_{\mathrm{epi}(w)}(x, t)$ if $w(x) \leqslant t$, (7.6.8) implies that (7.6.6) is equivalent to (7.6.7). In its turn, (7.6.6) is equivalent to (7.6.3). On the other hand, since (7.6.8) is satisfied, condition (C_1) is equivalent to the viability of epi(w) with respect to H. Indeed, if $w(x) < t$, and $(X, Y) : [0, T] \to \mathbb{R}^n \times \mathbb{R}$ is a solution to (7.6.2) with $(X(0), Y(0)) = (x, w(x))$, and $w(X(s)) \leqslant Y(s)$ for all $s \in [0, T]$, then the function $s \mapsto (X(s), Y(s) + t - w(x)) = (\overline{X}(s), \overline{Y}(s))$ is a solution to (7.6.2) with $(\overline{X}(0), \overline{Y}(0)) = (x, t)$ and satisfies $w(\overline{X}(s)) \leqslant \overline{Y}(s)$ for all $s \in [0, T]$. This completes the proof of (a). The proof of (b) goes in the very same spirit, and therefore we do not give details. □

REMARK 7.6.1. The property (C_1) is related to the so-called *weakly decreasing systems* discussed in Clarke et al. [34, p. 211], which in turn are related to the Liapunov theory of stabilization. See also [34, p. 208]. The "monotone variant" of (C_1) labelled below as (C_3) is connected to the so-called *strongly decreasing systems* discussed also in [34, p. 217].

(C_3) *For each $x \in \Omega$ there exists a solution $(X, Y) : [0, T] \to \mathbb{R}^n \times \mathbb{R}$ of the differential inclusion* (7.6.2) *with $(X(0), Y(0)) = (x, w(x))$, such that the function $s \mapsto w(X(s)) - Y(s)$ is decreasing.*

We have:

THEOREM 7.6.5. *Let $H : \Omega \times \mathbb{R} \rightsquigarrow \mathbb{R}^n \times \mathbb{R}$ be a u.s.c., nonempty and convex valued multifunction. Let, us assume that* (7.6.8) *is satisfied. Then, a continuous function w satisfies* (C_1) *if and only if it satisfies* (C_3).

PROOF. On epi(w) we define a relation $\mathcal{P}$ by

$$\mathcal{P}(x, t) = \big\{(y, s);\ w(y) - s \leqslant w(x) - t\big\}.$$

Obviously, $\mathcal{P}$ is a preorder on epi(w) and condition (C_3) is equivalent to the viability of the preorder $\mathcal{P}$ with respect to H. Moreover, condition (C_1) is equivalent to the viability of $\mathcal{P}(x, t)$ with respect to H for each $(x, t) \in \mathrm{epi}(w)$. The conclusion follows from Lemma 6.6.1. □

8. Notes and comments

8.1. *The upper semicontinuous case*

Since of its birth in 1942, viability theory emerged in several directions we will discuss sequentially below. The first viability result for the multivalued case is due to Bebernes and Schuur [6]. We mention that, in 1936, Zaremba [111] proved that if $F:\mathbb{D}\rightsquigarrow\mathbb{R}^n$ is u.s.c. with nonempty compact and convex values and $\mathbb{D}$ is open then, for each $\xi\in\mathbb{D}$, the differential inclusion (6.2.1) has at least one solution $u:[0,T]\to\mathbb{D}$ satisfying $u(0)=\xi$. It should be noticed that the concept of solution used by Zaremba in [111] is in the sense of the *contingent derivative*. More precisely, if $u:[0,T]\to\mathbb{R}^n$ is continuous and $t\in[0,T)$, the set

$$Du(t)=\left\{\lim_{m\to\infty}\frac{u(t+t_m)-u(t)}{t_m};\ t_m\downarrow 0\right\}$$

is called the *contingent derivative* of u at t. We say that $u:[0,T]\to\mathbb{D}$ is a *contingent solution* of (6.2.1) if

$$\emptyset\neq Du(t)\subseteq F\big(u(t)\big) \tag{8.1.1}$$

for each $t\in[0,T)$. In 1961, Ważewski [107] proved that, if F is u.s.c. with nonempty, compact and convex values, u is a contingent solution to (6.2.1) if and only if u is a Carathéodory solution to (6.2.1). So, Zaremba's existence result in [111] is nothing than the multivalued counterpart of Peano's local existence theorem 1.1.1. In the same spirit, the viability result of Bebernes and Schuur is the multivalued version of Nagumo's viability theorem 1.1.3. Proposition 8.1.1 below, due to Ważewski [107], is in fact equivalent to the necessity part of Theorem 6.2.1.

PROPOSITION 8.1.1. *Let $\mathbb{K}\subseteq\mathbb{R}^n$ be nonempty and locally closed and let $F:\mathbb{K}\rightsquigarrow\mathbb{R}^n$ be u.s.c. with nonempty, convex, compact values. Then, for every $\xi\in\mathbb{K}$, and every solution $u:[0,T]\to\mathbb{K}$ to* (6.2.1), *with $u(0)=\xi$, there exist $\eta\in F(\xi)$ and a sequence $(t_m)_m$ in $(0,T)$ convergent to* 0 *such that the sequence $(\frac{1}{t_m}(u(t_m)-\xi))_m$ converges to η.*

It is interesting to notice that, by using the viability theory developed in Section 6.1 for the locally closed set $\mathbb{K}=\{(t,u(t));\ t\in[0,T]\}$ and the multifunction $\{1\}\times F$, we can prove (see [22]) that condition (8.1.1) is also equivalent to each one of the following:

(i) $Du(t)\cap F(u(t))\neq\emptyset$ for each $t\in[0,T)$, or

(ii) $\overline{\mathrm{co}}\,Du(t)\cap F(u(t))\neq\emptyset$ for each $t\in[0,T)$.

In 1981, Haddad [52] obtained the first result on viability of preorders. In fact, Haddad adapted the proof of viability of sets in order to obtain viability of preorders. Cârjă and Ursescu [25] showed that the viability, as well as the invariance of preorders can be completely described in terms of viability, or invariance of sets. See Section 3.8.

The structure of the set of viable solutions of a differential inclusion on a subset $\mathbb{K}$, for which $\Pi_{\mathbb{K}}$ has continuous selections, was studied by Plaskacz [82]. See also the references therein.

As far as the infinite dimensional case is concerned, i.e. the case in which instead of $\mathbb{R}^n$ we are considering an infinite-dimensional Banach space X, we mention the pioneering contribution of Gauthier [48]. First, he used Zorn's Lemma in order to get approximate solutions defined on an a priori given interval. Second, he used a sufficient weak tangency condition of the form: *for each* $\xi \in \mathbb{K}$, *there exist* $\eta \in F(\xi)$, *a sequence* $(h_m)_m$ *decreasing to* 0, *a sequence* $(q_m)_m$ *weakly convergent to* 0 *satisfying* $\|q_m + \eta\| \leqslant 2\|\eta\|$ *and* $\xi + h_m(\eta + q_m) \in \mathbb{K}$ *for each* $m \in \mathbb{N}$. This tangency is far from being necessary for the viability of $\mathbb{K}$. A necessary and sufficient condition for the viability of $\mathbb{K}$ in a more general setting has been obtained by Cârjă and Vrabie [27] by means of the so-called "bounded weak tangency condition".

8.2. *The case of Carathéodory mappings*

The first viability result in the case of a single-valued Carathéodory right-hand side is due to Ursescu [98]. Theorem 5.2.1 is an extension of Ursescu's result in [98] which contains only the equivalence between (ii) and (vi) in the above mentioned theorem.

Although not presented here, the Carathéodory case for differential inclusions is well developed and there exists a rather large literature on the subject. Among the first notable results in this direction we mention those of Tallos [92], Ledyaev [64], Frankowska et al. [45]. In all these papers, theorems of Scorza Dragoni type are the main tools. Results of the same kind as in Theorem 5.2.1, but for differential inclusions, can be found in Cârjă and Monteiro Marques [22] in the finite-dimensional case, and in Cârjă and Monteiro Marques [23] in the infinite-dimensional setting. There, a technique of approximation (as in Theorem 5.2.1) of the multifunction through the Aumann integral mean is used.

8.3. *The lower semicontinuous case*

The next example shows that the convexity condition on the values of F is essential in obtaining the viability of a locally closed set $\mathbb{K}$ with respect to a u.s.c. multifunction $F : \mathbb{K} \rightsquigarrow \mathbb{R}^n$ by means of the tangency condition $\mathcal{T}_{\mathbb{K}}(\xi) \cap F(\xi) \neq \emptyset$ for all $\xi \in \mathbb{K}$.

EXAMPLE 8.3.1 (Aubin and Cellina [3, p. 202]). Let $n = 2$, $\mathbb{K} = B(0, 1)$ and $F : \mathbb{K} \to \mathbb{R}^2$, defined by $F(\xi) = \{(-1, 0), (1, 0)\}$ for each $\xi \in \mathbb{K}$. Then, one may easily see that $\mathbb{K}$ is locally closed (in fact closed and convex), F is u.s.c., satisfies the tangency condition, but nevertheless $\mathbb{K}$ is not viable with respect to F.

The lack of convexity of the values of F can be however counterbalanced by an l.s.c. extra-assumption combined with the stronger tangency condition

$$F(\xi) \subseteq \mathcal{T}_{\mathbb{K}}(\xi) \tag{8.3.1}$$

for each $\xi \in \mathbb{K}$. More precisely, we have:

THEOREM 8.3.1 (Aubin and Cellina [3, p. 198]). *Let $\mathbb{K}$ be locally closed and let $F:\mathbb{K}\rightsquigarrow\mathbb{R}^n$ be both u.s.c. and l.s.c. with nonempty and closed values. If* (8.3.1) *is satisfied, then $\mathbb{K}$ is viable with respect to F. Moreover, x' is a regulated function.*[5]

We emphasize that even for the convex-valued case, l.s.c. and (8.3.1) do not ensure invariance (see the case of functions), but implies viability via the Michael's selection theorem [67,68].

8.4. *The semilinear single-valued case*

Another direction was to consider a larger framework in order to handle semilinear partial differential equations as well. To this aim, let us consider an infinite dimensional Banach space X with norm $\|\cdot\|$ and let $\mathcal{L}(X)$ be the space of all linear bounded operators from X to X, endowed with the usual *operator norm* $\|\cdot\|_{\mathcal{L}(X)}$. We recall that $\{S(t);\ t\geqslant 0\}\subseteq\mathcal{L}(X)$ is a C_0*-semigroup* if

(i) $S(0)=I$;
(ii) $S(t+s)=S(t)S(s)$ for all $t,s\geqslant 0$;
(iii) $\lim_{h\downarrow 0}S(h)\xi=\xi$ for each $\xi\in X$.

The *infinitesimal generator* of $\{S(t);\ t\geqslant 0\}$ is the possibly unbounded linear operator $A:D(A)\subseteq X\to X$, defined by

$$\begin{cases} D(A)=\left\{\xi\in X;\ \exists\lim\limits_{h\downarrow 0}\dfrac{1}{h}\big[S(h)\xi-\xi\big]\right\},\\ A\xi=\lim\limits_{h\downarrow 0}\dfrac{1}{h}\big[S(h)\xi-\xi\big]\quad\text{for }\xi\in D(A).\end{cases}$$

Further, if $\{S(t);\ t\geqslant 0\}$ is a C_0-semigroup, $A:D(A)\subseteq X\to X$ is its infinitesimal generator and $\xi\in D(A)$, then the mapping $t\mapsto S(t-\tau)\xi$ is the unique classical, i.e., C^1, solution to the ordinary homogeneous differential equation

$$\begin{cases} u'=Au,\\ u(\tau)=\xi,\end{cases}\tag{8.4.1}$$

defined on $[\tau,+\infty)$. Moreover, since $D(A)$ is dense in X, it follows that, for each $\xi\in X$, the mapping $t\mapsto S(t-\tau)\xi$, which may fail to be C^1, can be approximated uniformly on compact subsets in $[\tau,+\infty)$ by classical solutions to problem (8.4.1). Thus, for each $\xi\in X$, the mapping above can be considered as a generalized solution of (8.4.1), called the *semigroup solution*. Furthermore, inspired from the variation of constants formula, we may define the so-called *mild, or C^0 solution*, $u:[\tau,a)\to X$, of the nonhomogeneous problem

$$\begin{cases} u'=Au+f(t),\\ u(\tau)=\xi,\end{cases}$$

---

[5] A function is *regulated* if it is uniform limit of step functions.

by

$$u(t) = S(t-\tau)\xi + \int_\tau^t S(t-s)f(s)\,\mathrm{d}s$$

for each $t \in [\tau, a)$. Here $f : [\tau, a) \to X$ is a given continuous, or even locally integrable, function and $a > \tau$ is finite or not. So, if $\mathbb{D} \subseteq X$ is a nonempty and open subset in X, $\mathbb{I}$ is a given nonempty open interval, $f : \mathbb{I} \times \mathbb{D} \to X$, $\tau \in \mathbb{I}$ and $\xi \in \mathbb{D}$, we may consider the *semilinear differential equation*

$$\begin{cases} u' = Au + f(t,u), \\ u(\tau) = \xi. \end{cases} \tag{8.4.2}$$

As expected, a *mild, or C^0 solution* of (8.4.2) is a continuous function $u : [\tau, T) \to \mathbb{D}$, with $T \in \mathbb{I}$, and satisfying

$$u(t) = S(t-\tau)\xi + \int_\tau^t S(t-s)f\big(s, u(s)\big)\,\mathrm{d}s \tag{8.4.3}$$

for each $t \in [\tau, T)$. For details on C_0-semigroups see Vrabie [105]. Further, if $\mathbb{K} \subseteq \mathbb{D}$ is locally closed, we redefine the concepts of right viability and right invariance of $\mathbb{K}$ with respect to $A + f$ by using mild or C^0 solutions. The main problem here is that, in general, $\mathbb{K} \cap D(A)$ is very narrow, even empty (we emphasize that $D(A)$ is only dense and could have empty interior), and therefore a necessary, or/and sufficient condition for viability of the type (1.1.3), i.e.

$$\liminf_{h \downarrow 0} \frac{1}{h} \operatorname{dist}\big(\xi + h\big[A\xi + f(t,\xi)\big]; \mathbb{K}\big) = 0, \tag{8.4.4}$$

for each $(t, \xi) \in \mathbb{I} \times [\mathbb{K} \cap D(A)]$, turns out to be unrealistic for nonsmooth semigroups. An example which justifies the remark above is that one when $\mathbb{K}$ is the trajectory of a nowhere differentiable right mild solution to (8.4.2), case in which $\mathbb{K} \cap D(A) = \emptyset$. The case of smooth semigroups (even nonlinear) was considered recently by Barbu and Pavel [5] by means of the tangency condition (8.4.4) with "lim" instead of "lim inf". It is the merit of Pavel [75] to observe that, in general, the really useful sufficient, and, very often, even necessary, condition for right viability which works in this case is

$$\lim_{h \downarrow 0} \frac{1}{h} \operatorname{dist}\big(S(h)\xi + hf(t,\xi); \mathbb{K}\big) = 0, \tag{8.4.5}$$

for each $(t, \xi) \in \mathbb{I} \times \mathbb{K}$. We notice that, whenever $\xi \in \mathbb{K} \cap D(A)$, (8.4.5) is equivalent to (8.4.4) which is a stronger form, i.e. with "lim inf" replaced by "lim", of the classical Nagumo's tangency condition (1.1.3) with $A + f$ instead of f. We re-emphasize that whenever $\mathbb{K}$ is not included in $D(A)$, or even $\mathbb{K} \cap D(A)$ is empty, the only tangency condition which could be of some use is (8.4.5). Namely, the main result in Pavel [75] is:

THEOREM 8.4.1 (Pavel [75]). *If $S(t)$ is compact for each $t > 0$ and $f : \mathbb{I} \times \mathbb{K} \to X$ is continuous, then a necessary and sufficient condition in order that $\mathbb{K}$ be right viable with respect to $(t, u) \mapsto Au + f(t, u)$ is* (8.4.5).

We notice that the compactness of $S(t)$ for each $t > 0$ is a parabolicity condition. The simplest nontrivial example of a C_0 semigroup satisfying this condition is that one occurring in the study of the heat flow. Namely, let $S(t) : L^2(0, \pi) \to L^2(0, \pi)$ be defined by

$$\big[S(t)\xi\big](x) = \sqrt{\frac{2}{\pi}} \sum_{k=1}^{\infty} a_k(\xi) \mathrm{e}^{-k^2 t} \sin kx$$

for $x \in (0, \pi)$, where $a_k(\xi)$ are the Fourier coefficients of ξ with respect to the orthogonal system $\big\{\sqrt{\frac{2}{\pi}} \sin x, \sqrt{\frac{2}{\pi}} \sin 2x, \ldots, \sqrt{\frac{2}{\pi}} \sin kx, \ldots\big\}$, i.e.

$$a_k(\xi) = \sqrt{\frac{2}{\pi}} \int_0^{\pi} \xi(y) \sin ky \, \mathrm{d}y.$$

It is well known that this semigroup defines the $L^2(0, \pi)$-solutions to the one-dimensional heat equation

$$\begin{cases} u_t = u_{xx} & \text{for } (t, x) \in [0, +\infty) \times (0, \pi), \\ u(t, 0) = u(t, \pi) & \text{for } t \in [0, +\infty), \\ u(0, x) = \xi & \text{for } x \in (0, \pi). \end{cases}$$

Moreover, for each $t > 0$, $S(t)$ is a compact, in fact even a Hilbert–Schmidt operator, because it is the limit in the operator norm of a sequence of finite-dimensional range operators. Indeed, a simple example of such sequence $(S_m(t))_m$ is

$$\big[S_m(t)\xi\big](x) = \sqrt{\frac{2}{\pi}} \sum_{k=1}^{m} a_k(\xi) \mathrm{e}^{-k^2 t} \sin kx$$

for $m = 1, 2, \ldots$ and each $\xi \in X$, where $a_k(\xi)$ are as above.

The extension of Pavel's Theorem 8.4.1 to Carathéodory perturbations has been considered by Cârjă and Monteiro Marques [21] for constant in time domains, and by Necula [71] for time dependent domains.

8.5. *The semilinear multivalued case*

As far as we know, the true semilinear and multivalued case, i.e. A linear unbounded and F multivalued, has been analyzed first by Pavel and Vrabie [78,79] by the end of seventies. A good source of references in this respect is Pavel [76]. Shi [91] considers the semilinear case (8.4.2) in which f is replaced by a multifunction, redefines the concept of viability by using strong solutions, i.e. continuous functions $u : [0, T) \to X$, $T \in (0, +\infty]$, which are absolutely continuous on $(0, T)$ and satisfy: $u'(t) = Au(t) + f(t)$ a.e. for $t \in [0, T)$, where $f \in L^\infty(0, T; X)$, $f(t) \in F(t, u(t))$ a.e. for $t \in (0, T)$, and proves a characterization of global viability, i.e. of right viability involving only strong solutions defined on $[0, +\infty)$.

THEOREM 8.5.1 (Shi [91]). *Let X be reflexive, $\mathbb{K}$ a compact subset of X, $F : X \rightsquigarrow X$ a nonempty, convex and compact valued upper semicontinuous mapping, and let $A : D(A) \subseteq X \to X$ be the infinitesimal generator of a differentiable C_0-semigroup $\{S(t);\ t \geqslant 0\}$ with $S(t)$ compact for all $t > 0$. Then a necessary and sufficient condition in order that $\mathbb{K}$ be right global viable with respect to F is the following tangency condition: for each $\xi \in \mathbb{K}$ there exist $\eta \in F(\xi)$, a sequence $(h_m)_m$ decreasing to 0 and a sequence $(p_m)_m$ strongly convergent to 0 such that*

$$S(h_m)\xi + h_m(\eta + p_m) \in \mathbb{K}$$

holds for each $m \in \mathbb{N}$.

As concerns sufficient conditions for global viability, we mention:

THEOREM 8.5.2 (Shi [91]). *Let X be reflexive, $\mathbb{K}$ a compact subset of X, $F : X \rightsquigarrow X$ a nonempty, bounded, closed and convex valued upper semicontinuous mapping, and let $A : D(A) \subseteq X \to X$ be the infinitesimal generator of a differentiable C_0-semigroup $\{S(t);\ t \geqslant 0\}$ with $S(t)$ compact for all $t > 0$. Then, a sufficient condition in order that $\mathbb{K}$ be right global viable with respect to F is the following tangency condition: for each $\xi \in \mathbb{K}$ and each $t > 0$ there exist $\eta \in F(\xi)$, a sequence $(h_m)_m$ decreasing to 0 and a sequence $(p_m)_m$ strongly convergent to 0 such that*

$$S(h_m)\xi + h_m\big(S(t)\eta + p_m\big) \in S(t)\mathbb{K}$$

holds for each $m \in \mathbb{N}$.

We note that the tangency condition in Theorem 8.5.2 is equivalent to:

$$AS(t)\xi + S(t)F(\xi) \subset \mathcal{T}_{S(t)\mathbb{K}}\big(S(t)\xi\big)$$

holds for each $\xi \in \mathbb{K}$ and each $t > 0$.

Clearly, in this case the general assumptions on $\mathbb{K}$ and F are significantly stronger than those in Pavel and Vrabie [78,79]. We note that for instance, in the infinite-dimensional setting, the compactness of $F(\xi)$ for each $\xi \in D$ is not satisfied if F is a superposition operator which is not single-valued. On the other hand, this “weakness” of the general setting of Shi [91] is well counterbalanced by the tangency condition which is quite close to its finite-dimensional counterpart.

The existence of monotone solutions has been considered in this context by Chiş-Şter [31].

8.6. *The nonlinear perturbed single-valued case*

Theorem 8.4.1 was partially extended by Vrabie [103] for the fully nonlinear case, i.e. when A m-dissipative. Namely, Vrabie [103] shows that, if A generates a nonlinear semigroup of nonexpansive compact, for $t > 0$, operators and $f : \mathbb{I} \times \mathbb{K} \to X$ is continuous on the locally closed subset $\mathbb{K}$, a sufficient condition for viability is

$$\lim_{h \downarrow 0} \frac{1}{h} \operatorname{dist}\bigl(u\bigl(t+h, t, \xi, f(t, \xi)\bigr); \mathbb{K}\bigr) = 0 \tag{8.6.1}$$

uniformly for $(t, \xi) \in \mathbb{I} \times \mathbb{K}$, where $u(\cdot, t, \xi, \eta)$ denotes the unique mild solution to the problem $u'(s) \in Au(s) + \eta$ satisfying $u(t, t, \xi, \eta) = \xi$. Subsequent contributions in this context are due to Bothe [14] who allowed $\mathbb{K}$ to depend on t as well. In particular, in case $\mathbb{K}$ independent of t, Bothe [14] showed that the, possibly non uniform, tangency condition (8.6.1) satisfied for each $(t, \xi) \in \mathbb{I} \times \mathbb{K}$ is necessary and sufficient for viability. The case of Carathéodory perturbations defined on time dependent domains has been considered by Necula [72].

8.7. *The multivalued perturbed nonlinear case*

The more delicate case in which one allows A to be nonlinear, as well as f to be multivalued, has been considered by Bressan and Staicu [17] who used the tangency condition proposed in Vrabie [103] after reducing the multivalued case to the single-valued one by means of a continuous selection argument. The case in which the multifunction F is strongly-weakly u.s.c. has been considered by Cârjă and Vrabie [28] by using a weak variant of the tangency condition in Vrabie [103], while the possibly nonconvex valued case has been analyzed by Necula and Vrabie [74] by using a selection theorem due to Fryszkowski [46].

8.8. *Applications*

The problem of finding Liapunov functions for differential inclusions is discussed in Aubin [1, Chapter 9], and Aubin and Cellina [3, Chapter 6]. As we have pointed out in Section 7.6, the characteristics method, when applied in control theory, is related to the dynamic programming method. Theorem 7.6.2 says that there is an equivalence between the Bellman equations (7.6.3) and (7.6.4) and the Bellman optimality conditions (C_1) and (C_2). If we want to study the uniqueness properties of the Bellman equation, we have to add appropriate boundary conditions and to use conditions (C_1) and (C_2) in order to get that a possible solution is necessarily the value function of the given control problem. The notion of solution for the couple of inequalities (7.6.3) and (7.6.4), defined in Section 7.6, is usually called *contingent solution*. It is interesting to notice that this kind of solution is equivalent with that of viscosity solution developed by Crandall and Lions [39]. However, the standard technique to get uniqueness is different here. Among the first contributions in this area we mention Frankowska [44] and Cârjă and Ursescu [26]. See also the more recent article of Aubin [2] and the references therein. For other applications of viability and invariance techniques to Control Theory and Game Theory, we refer the reader to Aubin and Cellina [3, Chapter 5]. As concerns the existence theory for periodic problems via viability and/or invariance see Aubin and Cellina [3, Chapter 5] and Vrabie [104]. For applications to the existence of constrained solutions to nonlinear partial differential inclusions see Bothe [15].

Finally, it should be noticed that the theory of invariant sets pertains a very elegant approach to the study of orbital motions of a mass particle in a given force field. This was pointed out by means of a second order tangency concept by Pavel and Ursescu [77].

Appendix

THEOREM A.1.1. *Let* $p \in [1, +\infty)$ *and let* $[\tau, T] \subseteq \mathbb{I}$. *A subset* $\mathcal{F}$ *in* $L^p_{\mathrm{loc}}(\mathbb{I}; \mathbb{R}^n)$ *is relatively compact in* $L^p(\tau, T; \mathbb{R}^n)$ *if and only if it is bounded and*

$$\lim_{\theta \downarrow 0} \int_\tau^{T-\theta} \left\| f(s+\theta) - f(s) \right\| \mathrm{d}s = 0$$

uniformly for $f \in \mathcal{F}$.

See Vrabie [105, Theorem A.4.1, p. 305]. For the proof of the next result see Dunford and Schwartz [40, Theorem 15, p. 150].

THEOREM A.1.2 (Vitali). *Let* $1 \leqslant p < +\infty$, *let* $\mathbb{S}$ *be a Lebesgue measurable subset in* $\mathbb{R}$, *and let* $(f_m)_m$ *be a sequence in* $L^p(\mathbb{S}; \mathbb{R}^n)$ *converging almost everywhere to a function* f. *Then* $f \in L^p(\mathbb{S}; \mathbb{R}^n)$ *and*

$$\lim_m \| f_m - f \|_{L^p(\mathbb{S};\mathbb{R}^n)} = 0$$

if and only if:

(i) $\{\| f_m \|^p;\ m \in \mathbb{N}\}$ *is uniformly integrable in* $L^1(\mathbb{S}; \mathbb{R}^n)$;

(ii) *for each* $\varepsilon > 0$ *there exists a Lebesgue measurable set* $\mathbb{E}_\varepsilon \subseteq \mathbb{S}$ *with* $\lambda(\mathbb{E}_\varepsilon) < +\infty$ *and such that, for each* $m \in \mathbb{N}$, *we have*

$$\int_{\mathbb{S} \setminus \mathbb{E}_\varepsilon} \left\| f_m(s) \right\|^p \mathrm{d}s < \varepsilon.$$

We recall that a subset $\mathcal{F}$ in $L^1(\mathbb{S}; \mathbb{R}^n)$ is uniformly integrable if

$$\lim_{\lambda(\mathbb{E}) \downarrow 0} \int_{\mathbb{E}} \left\| f(s) \right\| \mathrm{d}s = 0$$

uniformly for $f \in \mathcal{F}$. We notice that whenever $\mathbb{S}$ is a finite length interval, the condition (ii) is automatically satisfied.

0. Introduction

This chapter surveys a restricted but useful class of dynamical systems, namely, those enjoying a comparison principle with respect to a closed order relation on the state space. Such systems, variously called monotone, order-preserving or increasing, occur in many biological, chemical, physical and economic models.

The following notation will be used. $\mathbb{Z}$ denotes the set of integers; $\mathbb{N} = \{0, 1, \ldots\}$, the set of natural numbers; $\mathbb{N}_+$ is the set of positive integers, and $\mathbb{R}$ is the set of real numbers. For $u, v \in \mathbb{R}^n$ (= Euclidean n-space), we write

$$\begin{aligned} u \leqslant v \quad &\Longleftrightarrow \quad u_i \leqslant v_i, \\ u < v \quad &\Longleftrightarrow \quad u_i \leqslant v_i, \quad u \neq v, \\ u \ll v \quad &\Longleftrightarrow \quad u_i < v_i, \end{aligned}$$

where $i = 1, \ldots, n$. This relation $\leqslant$ is called the *vector order* in $\mathbb{R}^n$.

The prototypical example of monotone dynamics is a Kolmogorov model of cooperating species,

$$\dot{x}_i = x_i G_i(x), \quad x_i \geqslant 0, \quad i = 1, \ldots, n \tag{0.1}$$

in the positive orthant $\mathbb{R}^n_+ = [0, \infty)^n$, where $G : \mathbb{R}^n_+ \to \mathbb{R}^n$ is continuously differentiable. x_i denotes the population and G_i the *per capita* growth rate of species i. Cooperation means that an increase in any population causes an increase of the growth rates of all the other populations, modeled by the assumption that $\partial G_i / \partial x_j \geqslant 0$ for $i \neq j$. The right-hand side $F_i = x_i G_i$ of (0.1) then defines a *cooperative vector field* $F : \mathbb{R}^n \to \mathbb{R}^n$, meaning that $\partial F_i / \partial x_j \geqslant 0$ for $i \neq j$.

Assume for simplicity that solutions to Eq. (0.1) are defined for all $t \geqslant 0$. Let $\Phi = \{\Phi_t : \mathbb{R}^n_+ \to \mathbb{R}^n_+\}_{t \geqslant 0}$ denote the resulting semiflow in $\mathbb{R}^n_+$ that describes the evolution of states in positive time: the solution with initial value u is given by $x(t) = \Phi_t(u)$. The key to the long-term dynamics of cooperative vector fields is an important differential inequality due to Müller [148] and Kamke [91].

$$u \leqslant v \text{ and } t \geqslant 0 \quad \Longrightarrow \quad \Phi_t(u) \leqslant \Phi_t(v).$$

In other words: *The maps Φ_t preserve the vector order*. A semiflow Φ with this property is called *monotone*. Monotone semiflows and their discrete-time counterparts, order-preserving maps, form the subject of Monotone Dynamics.

Returning to the biological setting, we may make the assumption that each species directly or indirectly affect all the others. This is modeled by the condition that the Jacobian matrices $G'(x)$ are irreducible. An extension of the Müller–Kamke theorem shows that in the *open orthant* $\operatorname{Int} \mathbb{R}^n$, the restriction of Φ is *strongly monotone*: If $u, v \in \operatorname{Int} \mathbb{R}^n$, then

$$u < v \text{ and } t > 0 \quad \Longrightarrow \quad \Phi_t(u) \ll \Phi_t(v).$$

A semiflow with this property is *strongly monotone*.

Similar order-preserving properties are found in other dynamical settings, including delay differential equations and quasilinear parabolic partial differential equations. Typically the state space is a subset of a (real) Banach space Y with a distinguished closed cone $Y_+ \subset Y$. An order relation is introduced by $x \geqslant y \Leftrightarrow x - y \in Y_+$. When Y is a space of real valued functions on some domain, Y_+ is usually (but not always) the cone of functions with values in $\mathbb{R}_+ := [0, \infty)$. When $Y = \mathbb{R}^n$, the cooperative systems defined above use the cone $\mathbb{R}^n_+$.

Equations (0.1) model an ecology of competing species if $\partial G_i/\partial x_j \leqslant 0$ for $i \neq j$. The resulting vector field K with components $K_i = x_i G_i$ is not generally cooperative, but its negative $F = -K$ *is* cooperative. Many dynamical properties of the semiflow of K can be deduced from that of F, which is monotone.

We will see that the long-term behavior of monotone systems is severely limited. Typical conclusions, valid under mild restrictions, include the following:

- If all forward trajectories are bounded, the forward trajectory of almost every initial state converges to an equilibrium.
- There are no attracting periodic orbits other than equilibria, because every attractor contains a stable equilibrium.
- In $\mathbb{R}^3$, every compact limit set that contains no equilibrium is a periodic orbit that bounds an invariant disk containing an equilibrium.
- In $\mathbb{R}^2$, each component of any solution is eventually increasing or decreasing.

Other cones in $\mathbb{R}^n$ are also used, especially the orthants defined by restricting the sign of each coordinate. For example, a system of two competing species can be modeled by ODEs

$$\dot{y}_i = y_i H_i(y); \quad y_i \geqslant 0, \quad i = 1, 2$$

with $\partial H_i/\partial y_j < 0$ for $i \neq j$. The coordinate change $x_1 = y_1$, $x_2 = -y_2$ converts this into a cooperative system in the second orthant K defined by $x_1 \geqslant 0 \geqslant x_2$. This system is thus both competitive and cooperative, albeit for different cones. Not surprisingly, the dynamics are very simple.

In view of such powerful properties of cooperative vector fields, it would be useful to know when a given field F in an open set $D \subset \mathbb{R}^n$ can be made cooperative or competitive by changing coordinates. The following sufficient condition appears to be due to DeAngelis et al. [39]; see also Smith [193], Hirsch [74]. Assume the Jacobian matrices $[a_{ij}(x)] = F'(x)$ have the following two properties:

(1) (Sign stability) If $i \neq j$ then a_{ij} does not change sign in D;

(2) (Sign symmetry) $a_{ij}a_{ji} \geqslant 0$ in D.

Let Γ be the combinatorial labeled graph with nodes $1, \ldots, n$ and an edge e_{ij} joining i and j labeled $\sigma_{ij} \in \{+, -\}$ if and only if $i \neq j$ and there exists $p \in D$ such that $\operatorname{sgn} a_{ij}(p) = \sigma_{ij} \neq 0$. Then F is cooperative (respectively, competitive) relative to some orthant if and only if in every closed loop in Γ the number of negative labels is even (respectively, odd).

Order-preserving dynamics also occur in discrete time systems. Consider a nonautonomous Kolmogorov system $\dot{x}_i = x_i H_i(t, x)$, where the map $H := (H_1, \ldots, H_n) : \mathbb{R} \times \mathbb{R}^n \to \mathbb{R}^n$ has period $\tau > 0$ in t. Denote by $T : \mathbb{R}^n_+ \to \mathbb{R}^n_+$ the Poincaré map, which to $x \in \mathbb{R}^n_+$ assigns $y(\tau)$ where $y(t)$ denotes the solution with initial value x. Then T is monotone provided the $\partial H_i/\partial x_j \geqslant 0$ for $i \neq j$, and strongly monotone in the open orthant when these matrices are also irreducible. Most of the results stated above have analogs for T.

Convergence and stability properties of several kinds of order-preserving semiflows are developed in Sections 1 and 2, in the setting of general ordered metric spaces. Section 3 treats ODEs whose flows preserve the order defined by a cone in $\mathbb{R}^n$. Delay differential equations are studied in Section 4. In Section 5 we present results on order-preserving maps. The final section applies the preceding results to second order quasilinear parabolic equations.

1. Strongly order-preserving semiflows

This section introduces the basic definitions and develops the main tools of monotone dynamics. Several results on density of quasiconvergent points are proved, and used to establish existence of stable equilibria.

1.1. *Definitions and basic results*

The setting is a semiflow $\Phi = \{\Phi_t\}_{0 \leqslant t < \infty}$ in a (partially) ordered metric space that preserves the weak order relation: $x \leqslant y$ implies $\Phi_t(x) \leqslant \Phi_t(y)$. Such semiflows, called *monotone*, have severely restricted dynamics; for example, in $\mathbb{R}^n$ with the vector ordering there cannot be stable periodic orbits other than equilibria. But for generic convergence theorems we need semiflows with the stronger property of being "strongly order preserving," together with mild compactness assumptions. In later sections we will see that these conditions are frequently encountered in applications. The centerpiece of this section is the Limit Set Dichotomy, a fundamental tool for the later theory.

1.1.1. *Ordered spaces* Let Z be a metric space and $A, B \subset Z$ subsets. The closure of A is denoted by $\overline{A}$ and its interior by Int A. The distance from A to B is defined as $\operatorname{dist}(A, B) := \inf_{a \in A, b \in B} d(a, b)$. When B is a singleton $\{b\}$ we may write this as $\operatorname{dist}(A, b) = \operatorname{dist}(b, A)$.

X always denotes an *ordered space*. This means X is endowed with a metric d and an order relation $\mathsf{R} \subset X \times X$. As usual we write $x \leqslant y$ to mean $(x, y) \in \mathsf{R}$, and the order relation is:

(i) reflexive: $x \leqslant x$ for all $x \in X$,
(ii) transitive: $x \leqslant y$ and $y \leqslant z$ implies $x \leqslant z$,
(iii) antisymmetric: $x \leqslant y$ and $y \leqslant x$ implies $x = y$.

In addition, the ordering is compatible with the topology in the following sense:

(iv) if $x_n \to x$ and $y_n \to y$ as $n \to \infty$ and $x_n \leqslant y_n$, then $x \leqslant y$.

This is just to say that R is a closed subset of $X \times X$.

We write $x < y$ if $x \leqslant y$ and $x \neq y$. Given two subsets A and B of X, we write $A \leqslant B$ ($A < B$) when $x \leqslant y$ ($x < y$) holds for each choice of $x \in A$ and $y \in B$. The relation $A \leqslant B$ *does not imply* "$A < B$ or $A = B$"!

The notation $x \ll y$ means that there are open neighborhoods U, V of x, y respectively such that $U \leqslant V$. Equivalently, (x, y) belongs to the interior of R. The relation $\ll$, sometimes referred to as the *strong ordering*, is transitive; in many cases it is empty. We write $x \geqslant y$ to mean $y \leqslant x$, and similarly for $>$ and $\gg$.

We call X an *ordered subspace* of an ordered space X' if $X \subset X'$, and the order and topology on X are inherited from X'. When this is this case, the relation $u < v$ for points $u, v \in X$ means the same thing whether u and v are considered as points of X, or points of X'. But there are simple examples for which $u \ll v$ is true in X', yet false in X.

Let X be an ordered space. The *lower boundary* of a set $U \subset X$ is the set of points x in the boundary of U such that every neighborhood of x contains a point $y \in U$ with $y > x$. The *upper boundary* of U is defined dually.

Two points $x, y \in X$ are *order related* if $x < y$ or $y < x$; otherwise they are *unrelated*. A subset of X is *unordered* if it does not contain order related points. The empty set and singletons are unordered.

The (closed) *order interval* determined by $u, v \in X$ is the closed set

$$[u, v] = [u, v]_X := \{x \in X\colon\ u \leqslant x \leqslant v\}$$

which may be empty. The *open order interval* is the open set

$$[[u, v]] = \{x \in X\colon\ u \ll x \ll v\}.$$

A subset of X is *order bounded* if it lies in an order interval, and *order convex* if it contains $[u, v]$ whenever it contains u and v.

A point $x \in X$ is *accessible from below* if there is a sequence $x_n \to x$ with $x_n < x$; such a sequence is said to approximate x from below. We define *accessible from above* dually, that is, by replacing $<$ with $>$. In most applications there is a dense open subset of points that are accessible from both above and below.

The *supremum* $\sup S$ of a subset $S \subset X$, if it exists, is the unique point a such that $a \geqslant S$ and $x \geqslant S \Rightarrow x \geqslant a$. The *infimum* $\inf S$ is defined dually, i.e., substituting $\leqslant$ for $\geqslant$. A *maximal element* of S is a point $a \in S$ such that $x \in S$ and $x \geqslant a$ implies $x = a$. A *minimal element* is defined dually.

The following basic facts are well known:

LEMMA 1.1. *Assume the ordered space X is compact.*

(i) *Every sequence in X that is increasing or decreasing converges.*
(ii) *If X is totally ordered, it contains a supremum and an infimum.*
(iii) *X contains a maximal element and a minimal element.*

PROOF. (i) If p and q denote subsequential limits, then $p \leqslant q$ and $q \leqslant p$, hence $p = q$.

(ii) For each $x \in X$, the set $B_x := \{y \in X\colon\ y \geqslant x\}$ is compact, and every finite family of such sets has nonempty intersection because X is totally ordered. Therefore there exists $a \in \bigcap_x B_x$, and clearly $a = \sup X$. Similarly, $\inf X$ exists.

(iii) Apply (ii) to a maximal totally ordered subset (using Zorn's lemma). □

An *ordered Banach space* is an ordered space whose underlying metric space is a Banach space Y, and such that the set $Y_+ = \{y \in Y\colon\ y \geqslant 0\}$ is a cone, necessarily closed and convex. Thus Y_+ is a closed subset of Y with the properties:

$$\mathbb{R}_+ \cdot Y_+ \subset Y_+, \qquad Y_+ + Y_+ \subset Y_+, \qquad Y_+ \cap (-Y_+) = \{0\}.$$

We always assume $Y_+ \neq \{0\}$.

When $\operatorname{Int} Y_+$ is nonempty we call Y a *strongly ordered* Banach space. In this case $x \ll y \Leftrightarrow y - x \in \operatorname{Int} Y_+$.

The most important examples of ordered Banach spaces are completions of normed vector spaces of real-valued functions on some set Ω, with the positive cone corresponding to nonnegative functions. This cone defines the *functional ordering*. The simplest case is obtained from $\Omega = \{1, 2, \dots, n\}$: here $Y = \mathbb{R}^n$ and $Y_+ = \mathbb{R}^n_+$, the *standard cone* comprising vectors with all components nonnegative. For the corresponding *vector ordering*, $x \leqslant y$ means that $x_i \leqslant y_i$ for all i. Other function spaces are used in Sections 4 and 6.

When Y is an ordered Banach space, the notation $X \subset Y$ tacitly assumes that X is an ordered subspace of Y (but not necessarily a linear subspace).

A subset S of an ordered Banach space is *p-convex* if it contains the line segment spanned by u, v whenever $u, v \in S$ and $u < v$.

1.1.2. *Semiflows* All maps are assumed to be continuous unless the contrary is indicated.

A *semiflow* on X is a map $\Psi : \mathbb{R}_+ \times X \to X$, $(t, x) \mapsto \Psi_t(x)$ such that:

$$\Psi_0(x) = x, \qquad \Psi_t\bigl(\Psi_s(x)\bigr) = \Psi_{t+s}(x) \quad (t, s \geqslant 0,\ x \in X).$$

Thus Ψ can be viewed as a collection of maps $\{\Psi_t\}_{t \in \mathbb{R}_+}$ such that Ψ_0 is the identity map of X and $\Psi_t \circ \Psi_s = \Psi_{t+s}$, and such that $\Psi_t(x)$ is continuous in (t, x).

A *flow* in a space M is a continuous map $\Psi : \mathbb{R} \times M \to M$, written $\Psi(t, x) = \Psi_t(x)$, such that

$$\Psi_0(x) = x, \qquad \Psi_t\bigl(\Psi_s(x)\bigr) = \Psi_{t+s}(x) \quad (t, s \in \mathbb{R}, x \in X).$$

Restricting a flow to $\mathbb{R}_+ \times M$ gives a semiflow. A C^1 vector field F on a compact manifold M, tangent to the boundary, generates a *solution flow*, for which the trajectory of x is the solution $u(t)$ to the initial value problem $\mathrm{d}u/\mathrm{d}t = F(u)$, $u(0) = x$.

The *trajectory* of x is the map $[0, \infty) \to X$, $t \mapsto \Psi_t(x)$; the image of the trajectory is the *orbit* $O(x, \Psi)$, denoted by $O(x)$ when Ψ is understood. When $O(x) = \{x\}$ then x is an *equilibrium*. The set of equilibria is denoted by E.

x and its orbit are called *T-periodic* if $T > 0$ and $\Psi_T(x) = x$; such a T is a *period* of x. In this case $\Psi_{t+T}(x) = \Psi_t(x)$ for all $t \geqslant 0$, so $O(x) = \Psi([0, T] \times \{x\})$. A periodic point is *nontrivial* if it is not an equilibrium.

A set $A \subset X$ is *positively invariant* if $\Psi_t A \subset A$ for all $t \geqslant 0$. It is *invariant* if $\Psi_t A = A$ for all $t \geqslant 0$. Orbits are positively invariant and periodic orbits are invariant.

A set K is said to *attract* a set S if for every neighborhood U of K there exists $t_0 \geqslant 0$ such that $t > t_0 \Rightarrow \Psi_t(S) \subset U$; when $S = \{x\}$ we say K attracts x. An *attractor* is a nonempty invariant set L that attracts a neighborhood of itself. The union of all such neighborhoods is the *basin* of L. If the basin of an attractor L is all of X then L is a *global attractor*.

The *omega limit set* of $x \in X$ is

$$\omega(x) = \omega(x, \Psi) := \bigcap_{t \geqslant 0} \overline{\bigcup_{s \geqslant t} \Psi_s(x)}.$$

This set is closed and positively invariant. When $\overline{O(x)}$ is compact, $\omega(x)$ is nonempty, compact, invariant and connected and it attracts $\overline{O(x)}$ (see, e.g., Saperstone [175]).

A point $x \in X$ is *quasiconvergent* if $\omega(x) \subset E$; the set of quasiconvergent points is denoted by Q. We call x *convergent* when $\omega(x)$ is singleton $\{p\}$; in this case $\Phi_t(x) \to p \in E$. We sometimes signal this by the abuse of notation $\omega(x) \in E$. The set of convergent points is denoted by C.

When all orbit closures are compact and E is totally disconnected (e.g., countable), then $Q = C$; because in this case every omega limit set, being a connected subset of E, is a singleton. For systems of ordinary differential equations generated by smooth vector fields, the Kupka–Smale theorem gives generic conditions implying that E is discrete (see Peixoto [157]); but in concrete cases it is often difficult to verify these conditions.

1.1.3. *Monotone semiflows* A map $f : X_1 \to X_2$ between ordered spaces is *monotone* if

$$x \leqslant y \quad \Longrightarrow \quad f(x) \leqslant f(y),$$

strictly monotone if

$$x < y \quad \Longrightarrow \quad f(x) < f(y),$$

and *strongly monotone* if

$$x < y \quad \Longrightarrow \quad f(x) \ll f(y).$$

Let Φ denote a semiflow in the ordered space X. We call Φ monotone or strictly monotone according as each map Φ_t has the corresponding property.

We call Φ *strongly order-preserving*, SOP for short, if it is monotone and whenever $x < y$ there exist open subsets U, V of x, y respectively, and $t_0 \geqslant 0$, such that

$$\Phi_{t_0}(U) \leqslant \Phi_{t_0}(V).$$

Monotonicity of Φ then implies that $\Phi_t(U) \leqslant \Phi_t(V)$ for all $t \geqslant t_0$.

We call Φ *strongly monotone* if

$$x < y,\ 0 < t \quad \Longrightarrow \quad \Phi_t(x) \ll \Phi_t(y)$$

and *eventually strongly monotone* if it is monotone and whenever $x < y$ there exists $t_0 > 0$ such that

$$t \geqslant t_0 \quad \Longrightarrow \quad \Phi_t(x) \ll \Phi_t(y).$$

This property obviously holds when Φ is strongly monotone. We shall see in Section 6 that many parabolic equations generate SOP semiflows in function spaces that are not strongly ordered and therefore do not support strongly monotone semiflows.

Strong monotonicity was introduced in Hirsch [68,69], while SOP was proposed later by Matano [133,134] and modified slightly by Smith and Thieme [197,199]. We briefly explore the relation between these two concepts.

PROPOSITION 1.2. *If Φ is eventually strongly monotone, it is SOP. If X is an open subset of a Banach space Y ordered by a cone Y_+, Φ is SOP and the maps $\Phi_t : X \to X$ are open, then Φ is eventually strongly monotone. In particular, Φ is eventually strongly monotone provided Y is finite-dimensional, Φ is SOP and the maps Φ_t are injective.*

PROOF. If $x < y$ and Φ is eventually strongly monotone, then there exists $t_0 > 0$ such that $\Phi_{t_0}(x) \ll \Phi_{t_0}(y)$. Take neighborhoods $\widetilde{U}$ of $\Phi_{t_0}(x)$ and $\widetilde{V}$ of $\Phi_{t_0}(y)$ such that $\widetilde{U} < \widetilde{V}$. By continuity of Φ_{t_0}, there are neighborhoods U of x and V of y such that $\Phi_{t_0}(U) \subset \widetilde{U}$ and $\Phi_{t_0}(V) \subset \widetilde{V}$. Therefore, $\Phi_{t_0}(U) < \Phi_{t_0}(V)$ so Φ is SOP.

Suppose that $X \subset Y$ is open and ordered by Y_+ and Φ is SOP. If $x < y$ and U, V are open neighborhoods as in the definition of SOP, the inequality $\Phi_t(U) \leqslant \Phi_t(V)$ together with the fact that $\Phi_t(U)$ and $\Phi_t(V)$ are open in Y imply that $\Phi_t(x) \ll \Phi_t(y)$. ☐

The following very useful result shows that the defining property of SOP semiflows, concerning points $x < y$, extends to a similar property for compact sets $K < L$:

LEMMA 1.3. *Assume Φ is SOP and K, L are compact subsets of X satisfying $K < L$. Then there exists real numbers $t_1 \geqslant 0$, $\epsilon > 0$ and neighborhoods U, V of K, L respectively such that*

$$t \geqslant t_1 \quad \textit{and} \quad 0 \leqslant s \leqslant \epsilon \quad \Longrightarrow \quad \Phi_{t+s}(U) \leqslant \Phi_t(V).$$

PROOF. Let $x \in K$. For each $y \in L$ there exist $t_y \geqslant 0$, a neighborhood U_y of x, and a neighborhood V_y of y such that $\Phi_t(U_y) \leqslant \Phi_t(V_y)$ for $t \geqslant t_y$ since Φ is strongly order preserving. $\{V_y\}_{y\in L}$ is an open cover of L, so we may choose a finite subcover: $L \subset \bigcup_{i=1}^n V_{y_i} := \widetilde{V}$ where $y_i \in L$, $1 \leqslant i \leqslant n$. Let $\widetilde{U}_x = \bigcap_{i=1}^n U_{y_i}$, which is a neighborhood of x, and let $\tilde{t}_x = \max_{1\leqslant i\leqslant n} t_{y_i}$. Then $\Phi_{\tilde{t}}(\widetilde{U}_x) \subset \Phi_{\tilde{t}}(U_{y_i}) \leqslant \Phi_{\tilde{t}}(V_{y_i})$, so $\Phi_t(\widetilde{U}_x) \leqslant \Phi_t(V_{y_i})$ for $t \geqslant \tilde{t}_x$. It follows that

$$t \geqslant \tilde{t}_x \quad \Longrightarrow \quad \Phi_t\big(\widetilde{U}_x\big) \leqslant \Phi_t\big(\widetilde{V}\big).$$

Extract a finite subcover $\{\widetilde{U}_{x_j}\}$ of K from the family $\{\widetilde{U}_x\}$. Setting $U := \bigcup_j \widetilde{U}_{x_j} \supset K$ and $t_1 := \max_{1\leqslant j\leqslant m} \tilde{t}_{x_j}$, we have

$$t \geqslant t_1 \quad\Longrightarrow\quad \Phi_t(U) = \bigcup_j \Phi_t\big(\widetilde{U}_j\big) \leqslant \Phi_t(V).$$

In order to obtain the stronger conclusion of the lemma, note that for each $z \in K$ there exists $\epsilon_z > 0$ and a neighborhood U'_z of z such that $\Phi([0,\epsilon_z) \times W_z) \subset U$. Choose $z_1, \dots, z_m$ in K so that $K \subset \bigcup_j U'_{z_j}$. Define $U' = \bigcup_j U'_{z_j}$ and $\epsilon = \min_j\{\epsilon_{z_j}\}$. If $x \in U'$ and $0 \leqslant s < \epsilon$ then $x \in U'_{z_j}$ for some j so $\Phi_s(x) \in U$. Thus $\Phi([0,\epsilon) \times U') \subset U$ so $\Phi_s(U') \subset U$. It follows that $\Phi_{t+s}(U') \subset \Phi_t(U) \leqslant \Phi_t(V)$ for $t \geqslant t_1$, $0 \leqslant s < \epsilon$. □

Several fundamental results in the theory of monotone dynamical systems are based on the following sufficient conditions for a solution to converge to equilibrium.

THEOREM 1.4 (Convergence Criterion). *Assume Φ is monotone, $x \in X$ has compact orbit closure, and $T > 0$ is such that $\Phi_T(x) \geqslant x$. Then $\omega(x)$ is an orbit of period T. Moreover, x is convergent if the set of such T is open and nonempty or Φ is SOP and $\Phi_T(x) > x$.*

PROOF. Monotonicity implies that $\Phi_{(n+1)T}(x) \geqslant \Phi_{nT}(x)$ for $n = 1, 2, \dots$ and therefore $\Phi_{nT}(x) \to p$ as $n \to \infty$ for some p by the compactness of the orbit closure. By continuity,

$$\begin{aligned}\Phi_{t+T}(p) &= \Phi_{t+T}\Big(\lim_{n\to\infty} \Phi_{nT}(x)\Big)\\ &= \lim_{n\to\infty} \Phi_{(n+1)T+t}(x)\\ &= \lim_{n\to\infty} \Phi_t\big(\Phi_{(n+1)T}(x)\big)\\ &= \Phi_t(p)\end{aligned}$$

for all $t \geqslant 0$. Hence p is T-periodic.

To prove $\omega(x) = O(p)$, suppose $t_j \to \infty$ and $\Phi_{t_j}(x) \to q \in \omega(x)$ as $j \to \infty$, and write $t_j = n_j T + r_j$ where n_j is a natural number and $0 \leqslant r_j < T$. By passing to a subsequence if necessary, we may assume that $r_j \to r \in [0, T]$. Taking limits as $j \to \infty$ and noting that $n_j \to \infty$, we have by continuity:

$$\lim \Phi_{t_j}(x) = \lim \Phi_{r_j}\big(\lim \Phi_{n_j T}(x)\big) = \lim \Phi_{r_j}(p) = \Phi_r(p) = q.$$

Therefore $\omega(x) \subset O(p)$, and the opposite inclusion holds because $p \in \omega(x)$. This proves the first assertion of the theorem.

Suppose $\Phi_t(x) \geqslant x$ for all t in a nonempty open interval $(T - \epsilon, T + \epsilon)$. The first assertion shows that $\omega(x)$ is an orbit $O(p)$ of period τ for every $\tau \in (T - \epsilon, T + \epsilon)$. All elements of $O(p)$ have the same set G of periods; G is closed under addition and contains $(T - \epsilon, T + \epsilon)$. If $0 \leqslant s < \epsilon$ and $t \geqslant 0$ then

$$\Phi_{t+s}(p) = \Phi_t\big(\Phi_s(p)\big) = \Phi_t\big(\Phi_{s+T}(p)\big) = \Phi_t(p).$$

Hence $[0, \epsilon) \subset G$ and therefore $G = \mathbb{R}_+$, which implies $p \in E$. This proves the second assertion.

If $\Phi_T(x) > x$ and Φ is SOP then there exist neighborhoods U of x and V of $\Phi_T(x)$ and $t_0 > 0$ such that $\Phi_{t_0}(U) \leqslant \Phi_{t_0}(V)$. It follows that $\Phi_{t_0}(x) \leqslant \Phi_{t_0+T+\epsilon}(x)$ for all ϵ sufficiently small. The previous assertion implies $\omega(x) = p \in E$. □

1.2. *Nonordering of omega limit sets*

The next result is the first of several describing the order geometry of limit sets.

PROPOSITION 1.5 (Nonordering of Periodic Orbits). *A periodic orbit of a monotone semiflow is unordered.*

PROOF. Let x have minimal period $s > 0$ under a monotone semiflow Φ. Suppose $x \leqslant z \in O(x)$. By compactness of $O(x)$ there is a maximal $y \in O(x)$ such that $y \geqslant z \geqslant x$. By periodicity and monotonicity $y = \Phi_t(x) \leqslant \Phi_t(y)$, $t > 0$, hence $y = \Phi_t(y)$ by maximality. Therefore t is an integer multiple of s, so $x = \Phi_t(x) = y$, implying $x = z$. □

The following result, which implies (1.5), is a broad generalization of the obvious fact that for ODEs in $\mathbb{R}$, nonconstant solutions are everywhere increasing or everywhere decreasing. Let $J \subset \mathbb{R}$ be an interval and $f : J \to X$ a map. A compact subinterval $[a, b] \subset J$ is *rising* for f provided $f(a) < f(b)$, and *falling* if $f(b) < f(a)$.

THEOREM 1.6. *A trajectory of a monotone semiflow cannot have both a rising interval and a falling interval.*

This originated in Hirsch [67], with improvements in Smith [194], Smith and Waltman [203]. An analog for maps is given in Theorem 5.4.

PROOF. Let Φ be a monotone semiflow in X and fix a trajectory $f : [0, \infty) \to X$, $f(t) := \Phi_t(x)$. Call an interval $[d, d']$ *weakly falling* if $f(d) \geqslant f(d')$. Monotonicity shows that when this holds, the *right translates* of $[d, d']$—the intervals $[d + u, d' + u]$ with $u \geqslant 0$—are also weakly falling.

Proceeding by contradiction, we assume f has a falling interval $[a, a + r]$ and a rising interval $[c, c + q]$. To fix ideas we assume $a \leqslant c$, the case $c \leqslant a$ being similar. Define

$$b := \sup\bigl\{t \in [c, c + q]\colon\ f(t) \leqslant f(c),\ s := c + q - b\bigr\}.$$

Then $[b, b + s]$ is a rising interval in $[c, c + q]$, and

$$b < t \leqslant b + s \quad \Longrightarrow \quad f(t) \nleqslant f(b). \tag{1.1}$$

Claim 1: *No interval* $[b - l, b]$ *is weakly falling.* Assume the contrary. Then (i) $l > s$, and (ii) $[b - (l - s), b]$ is weakly falling. To see (i), observe that $f(b + l) \leqslant f(b)$ because

$[b, b+l]$ is a right translate of $[b-l, b]$; hence $l \leqslant s$ would entail $b < b+l \leqslant b+s$, contradicting (1.1) with $t = b+l$. To prove (ii), note that right translation of $[b-l, b]$ shows that $[b-l+s, b+s]$ is weakly falling, implying $f(b-(l-s)) \geqslant f(b+s) > f(b)$; hence $[b-(l-s), b]$ is falling. Repetition of this argument with l replaced by $l-s, l-2s, \ldots$ leads by induction on n to the absurdity that $l - ns > s$ for all $n \in \mathbb{N}$.

Claim 2: $r > s$. For $f(b+r) \leqslant f(b)$ because $[b, b+r]$ is falling, as it is a right translate of $[a, a+r]$. Therefore $r > s$, for otherwise $b < b+r \leqslant b+s$ and (1.1) leads to a contradiction.

As $b+s \geqslant a+r$, we can translate $[a, a+r]$ to the right by $(b+s)-(a+r)$, obtaining the weakly falling interval $[b+s-r, b+s]$. Note that $b+s-r < b$ by Claim 2. From $f(b+s-r) \geqslant f(b+s) > f(b)]$ we conclude that $[b-(r-s), b]$ is falling. But this contradicts Claim 1 with $l = r-s$. □

LEMMA 1.7. *An omega limit set for a monotone semiflow Φ cannot contain distinct points x, y having respective neighborhoods U, V such that $\Phi_r U \leqslant \Phi_r V$ for some $r \geqslant 0$.*

PROOF. We proceed by contradiction. Suppose there exist distinct points $x, y \in \omega(z)$ having respective neighborhoods U, V such that $\Phi_r U \leqslant \Phi_r V$ for some $r \geqslant 0$. Then $\omega(z)$ is not a periodic orbit, for otherwise from $\Phi_r(x) \leqslant \Phi_r(y)$ we infer $x \leqslant y$ and hence $x < y$, violating Nonordering of Periodic Orbits.

There exist real numbers $a < b < c$ be such that $\Phi_a(z) \in U$, $\Phi_b(z) \in V$, $\Phi_c(z) \in U$. Therefore the properties of r, U and V imply

$$\Phi_{a+r}(z) \leqslant \Phi_{b+r}(z), \qquad \Phi_{b+r}(z) \geqslant \Phi_{c+r}(z).$$

As $\omega(z)$ is not periodic, the semiflow is injective on the orbit of z; hence the order relations above are strict. But this contradicts Theorem 1.6. □

It seems to be unknown whether omega limit sets of monotone semiflows must be unordered. This holds for SOP semiflows by the following theorem due to Smith and Thieme [197, Proposition 2.2]; the strongly monotone case goes back to Hirsch [66]. This result is fundamental to the theory of monotone semiflows:

THEOREM 1.8 (Nonordering of Omega Limit Sets). *Let $\omega(z)$ be an omega limit set for a monotone semiflow Φ.*

(i) *No points of $\omega(z)$ are related by $\ll$.*

(ii) *If $\omega(z)$ is a periodic orbit or Φ is SOP, no points of $\omega(z)$ are related by $<$.*

PROOF. Assume $x, y \in \omega(z)$. If $\omega(z)$ is a periodic orbit then x, y are unrelated (Proposition 1.5). If $x \ll y$ or $x < y$ and Φ is SOP, there are respective neighborhoods U, V of x, y such that $\Phi_r(U) \leqslant \Phi_r(V)$ for some $r \geqslant 0$; but this violates Lemma 1.7. □

COROLLARY 1.9. *Assume Φ is SOP.*

(i) *If an omega limit set has a supremum or infimum, it reduces to a single equilibrium.*

(ii) *If the equilibrium set is totally ordered, every quasiconvergent point with compact orbit closure is convergent.*

PROOF. Part (i) follows from Theorem 1.8(ii), since the supremum or infimum, if it exists, belongs to the limit set. Part (ii) is a consequence of (i). □

1.3. *Local semiflows*

For simplicity we have assumed trajectories are defined for all $t \geqslant 0$, but there are occasions when we need the more general concept of a *local semiflow* in X. This means a map $\Psi : \Omega \to X$, with $\Omega \subset [0, \infty) \times X$ an open neighborhood of $\{0\} \times X$, such that the maps

$$\Psi_t : D_t \to X,\ x \mapsto \Psi(t, x) \quad (0 \leqslant t < \infty)$$

satisfy the following conditions: D_t is an open, possibly empty set in X, Ψ_0 is the identity map of X, and $\Psi_{s+t} = \Psi_s \circ \Psi_t$ in the sense that $D_{s+t} = D_t \cap \Psi_t^{-1}(D_s)$ and $\Psi_{s+t}(x) = \Psi_s(\Psi_t(x))$ for $x \in D_{s+t}$.

The trajectory of x is defined as the map

$$I_x \to X,\ t \mapsto \Psi_t(x), \quad \text{where } I_x = \{t \in \mathbb{R}_+ :\ x \in D_t\}.$$

The composition law implies I_x is a half open interval $[0, \tau_x)$; we call $\tau_x \in (0, \infty]$ the *escape time* of x. It is easy to see that every point with compact orbit closure has infinite escape time. Thus a local semiflow with compact orbit closures is a semiflow. In dealing with local semiflows we adopt the convention that the notations $\Psi_t(x)$ and $\Psi_t(U)$ carry the assumptions that $t \in I_x$ and $U \subset D_t$. The image of I_x under the trajectory of x is the orbit $O(x)$. The omega limit set $\omega(x)$ is defined as $\omega(x) = \bigcap_{t \in I_x} \overline{O(\Psi_t(x))}$.

A *local flow* is a map $\Theta : \Lambda \to X$ where $\Lambda \subset \mathbb{R} \times X$ is an open neighborhood of $\{0\} \times X$, and the (possibly empty) maps

$$\Theta_t : D_t \to X,\ x \mapsto \Theta(t, x) \quad (-\infty \leqslant t < \infty)$$

satisfy the following conditions: Θ_0 is the identity map of $D_0 := X$, Θ_t is a homeomorphism of D_t onto D_{-t} with inverse Θ_{-t}, and

$$x \in (\Theta_s)^{-1} D_r \quad \Longrightarrow \quad \Theta_r \circ \Theta_s(x) = \Theta_{r+s}(x).$$

Θ is a *flow* provided $D_t = X$ for all t.

The set $J_x := \{t \in \mathbb{R}:\ x \in D_t\}$ is an open interval around 0. The positive and negative *semiorbits* of x are the respective sets

$$\gamma^+(x) = \gamma^+(x, \Theta) := \bigl\{\Theta_t(x):\ t \in J_x, t \geqslant 0\bigr\},$$

$$\gamma^-(x) = \gamma^-(x, \Theta) := \bigl\{\Theta_t(x):\ t \in J_x, t \leqslant 0\bigr\}.$$

The *time-reversal* of Θ is the local flow $\widetilde{\Theta}$ defined by $\widetilde{\Theta}(t,x)=\Theta(-t,x)$.

The omega limit set $\omega(x)$ (for Θ) is defined to be $\omega(x)=\bigcap_{t\in I_x,t\geqslant 0}\overline{O(\Psi_t(x))}$. The *alpha limit set* $\alpha(x)=\alpha(x,\Theta)$ of x is defined as the omega limit set of x under the time-reversal of Θ^+.

Let F be a locally Lipschitz vector field F on a manifold M tangent along the boundary. Denote by $t\mapsto u(t;x)$ the maximally defined solution to $\dot{u}=F(u)$, $u(0,x)=x$. There is a local flow Θ^F on M such that $\Theta_t(x)=u(t;x)$. The time-reversal of Θ^F is Θ^{-F}. When M is compact, Θ^F is a flow. If we assume that F, rather than being tangent to the boundary, is transverse inward, we obtain a local semiflow.

Our earlier results are readily adapted to monotone local semiflows. In particular, omega limit sets are unordered. Theorems 1.8 and 1.6 have the following extension:

THEOREM 1.10. *Let Φ be a monotone local semiflow.*

(a) *No trajectory has both a rising and a falling interval.*
(b) *No points of an omega limit set are related by $\ll$, or by $<$ if Φ is SOP.*
(c) *The same holds for alpha limit sets provided Φ is a local flow.*

PROOF. The proofs of Theorems 1.6 and 1.8 also prove (a) and (b), and (c) follows by time reversal. □

1.4. *The limit set dichotomy*

Throughout the remainder of Section 1 we adopt the following assumptions:

(H) Φ is a strongly order preserving semiflow in an ordered space X, with every orbit closure compact.

Our goal now is to prove the important Limit Set Dichotomy:

If $x<y$ then either $\omega(x)<\omega(y)$, or $\omega(x)=\omega(y)\subset E$.

LEMMA 1.11 (Colimiting Principle). *Assume $x<y$, $t_k\to\infty$, $\Phi_{t_k}(x)\to p$ and $\Phi_{t_k}(y)\to p$ as $k\to\infty$. Then $p\in E$.*

PROOF. Choose neighborhoods U of x and V of y and $t_0>0$ such that $\Phi_{t_0}(U)\leqslant\Phi_{t_0}(V)$. Let $\delta>0$ be so small that $\{\Phi_s(x)\colon\ 0\leqslant s\leqslant\delta\}\subset U$ and $\{\Phi_s(y)\colon\ 0\leqslant s\leqslant\delta\}\subset V$. Then $\Phi_s(x)\leqslant\Phi_r(y)$ whenever $t_0\leqslant r,\ s\leqslant t_0+\delta$. Therefore,

$$\Phi_{t_k-t_0}\big(\Phi_s(x)\big)\leqslant\Phi_{t_k-t_0}\big(\Phi_{t_0}(y)\big)=\Phi_{t_k}(y)\tag{1.2}$$

for all $s\in[t_0,t_0+\delta]$ and all large k. As

$$\Phi_{t_k-t_0}\big(\Phi_s(x)\big)=\Phi_{s-t_0}\big(\Phi_{t_k}(x)\big)=\Phi_r\big(\Phi_{t_k}(x)\big),$$

where $r = s - t_0 \in [0, \delta]$ if $s \in [t_0, t_0 + \delta]$, we have

$$\Phi_r\big(\Phi_{t_k}(x)\big) \leqslant \Phi_{t_k}(y)$$

for large k and $r \in [0, \delta]$. Passing to the limit as $k \to \infty$ we find that $\Phi_r(p) \leqslant p$ for $0 \leqslant r \leqslant \delta$. If, in (1.2), we replace $\Phi_s(x)$ by $\Phi_{t_0}(x)$ and replace $\Phi_{t_0}(y)$ by $\Phi_s(y)$, and argue as above then we find that $p \leqslant \Phi_r(p)$ for $0 \leqslant r \leqslant \delta$. Evidently, $\Phi_r(p) = p$, $0 \leqslant r \leqslant \delta$ and therefore for all $r \geqslant 0$, so $p \in E$. $\square$

THEOREM 1.12 (Intersection Principle). *If $x < y$ then $\omega(x) \cap \omega(y) \subset E$. If $p \in \omega(x) \cap \omega(y)$ and $t_k \to \infty$, then $\Phi_{t_k}(x) \to p$ if and only if $\Phi_{t_k}(y) \to p$.*

PROOF. If $p \in \omega(x) \cap \omega(y)$ then there exists a sequence $t_k \to \infty$ such that $\Phi_{t_k}(x) \to p$ and $\Phi_{t_k}(y) \to q \in \omega(y)$, and $p \leqslant q$ by monotonicity. If $p < q$ then we contradict the Nonordering of Limit Sets since $p, q \in \omega(y)$. Hence $p = q$. The Colimiting Principle then implies $p \in E$. $\square$

The proof of the next result has been substantially simplified over previous versions.

LEMMA 1.13. *Assume $x < y$, $t_k \to \infty$, $\Phi_{t_k}(x) \to a$, and $\Phi_{t_k}(y) \to b$ as $k \to \infty$. If $a < b$ then $O(a) < b$ and $O(b) > a$.*

PROOF. The set $W := \{t \geqslant 0\colon \Phi_t(a) \leqslant b\}$ contains 0 and is closed. We prove $W = [0, \infty)$ by showing that W is also open. Observe first that if $t \in W$, then $\Phi_t(a) < b$. For equality implies $b \in \omega(x) \cap \omega(y) \subset E$, and then the Intersection Principle entails $\Phi_{t_k}(x) \to b$, giving the contradiction $a = b$.

Suppose $\bar{t} \in W$ is positive. By SOP there are open sets U, V with $\Phi_{\bar{t}}(a) \in U$, $b \in V$ and $t_1 \geqslant 0$ such that $\Phi_t(U) \leqslant \Phi_t(V)$ for $t \geqslant t_1$. There exists $\delta \in (0, \bar{t}/2)$ such that $\Phi_s(a) \in U$ for $|s - \bar{t}| \leqslant \delta$, so we can find an integer $\kappa > 0$ such that $\Phi_s(\Phi_{t_k}(x)) \in U$ for $k \geqslant \kappa$. Choose $k_0 \geqslant \kappa$ such that $\Phi_{t_{k_0}}(y) \in V$. Then we have $\Phi_{t+s+t_{k_0}}(x) \leqslant \Phi_{t+t_{k_0}}(y)$ for $t \geqslant t_1$. Setting $t = t_k - t_{k_0}$ for large k in this last inequality yields $\Phi_{t_k+s}(x) \leqslant \Phi_{t_k}(y)$ for large k. Taking the limit as $k \to \infty$ we get $\Phi_s(a) \leqslant b$ for $|s - \bar{t}| \leqslant \delta$. A similar argument in the case $\bar{t} = 0$ considering only $s \in [0, \delta]$ gives the previous inequality for such s. Therefore, W is both open and closed so $W = [0, \infty)$. This proves $O(a) < b$, and $O(b) > a$ is proved dually. $\square$

LEMMA 1.14 (Absorption Principle). *Let $u, v \in X$. If there exists $x \in \omega(u)$ such that $x < \omega(v)$, then $\omega(u) < \omega(v)$. Similarly, if there exists $x \in \omega(u)$ such that $\omega(v) < x$, then $\omega(v) < \omega(u)$.*

PROOF. Apply Lemma 1.3 to obtain open neighborhoods U of x and V of $\omega(v)$ and $t_0 > 0$ such that

$$r \geqslant t_0 \quad \Longrightarrow \quad \Phi_r(U) \leqslant \Phi_r(V),$$

hence $\Phi_r(U) \leqslant \omega(v)$ since $\omega(v)$ is invariant. As $x \in \omega(u)$, there exists $t_1 > 0$ such that $\Phi_{t_1}(u) \in U$. Hence for $\Phi_{t_0+t_1}(u) \leqslant \omega(v)$, and monotonicity implies that $\Phi_{s+t_0+t_1}(u) \leqslant$

$\omega(v)$ for all $s \geqslant 0$. This implies that $\omega(u) \leqslant \omega(v)$. If $z \in \omega(u) \cap \omega(v)$ then $z = \sup \omega(u) = \inf \omega(v)$, whence $\{z\} = \omega(u) = \omega(v)$ by Corollary 1.9(ii). But this is impossible since $x < \omega(v)$ and $x \in \omega(u)$, so we conclude that $\omega(u) < \omega(v)$. ☐

LEMMA 1.15 (Limit Set Separation Principle). *Assume $x < y$, $a < b$ and there is a sequence $t_k \to \infty$ such that $\Phi_{t_k}(x) \to a$, $\Phi_{t_k}(y) \to b$. Then $\omega(x) < \omega(y)$.*

PROOF. By Lemma 1.13, $O(a) < b$, and therefore $\omega(a) \leqslant b$. If $b \in \omega(a)$ then Corollary 1.9 implies that $\omega(a) = b \in E$. Applying the Absorption Principle with $u = x$, $v = a$, $x = a$, we have $a \in \omega(x)$, $a < \omega(a) = b$ which implies that $\omega(x) < \omega(a)$. This is impossible as $\omega(a) \subset \omega(x)$. Consequently, $\omega(a) < b$. By the Absorption Principle again (with $u = a$, $v = y$), we have $\omega(a) < \omega(y)$. Since $\omega(a) \subset \omega(x)$, the Absorption Principle gives $\omega(x) < \omega(y)$. ☐

We now prove the fundamental tool in the theory of monotone dynamics, stated for strongly monotone semiflows in Hirsch [66,68].

THEOREM 1.16 (Limit Set Dichotomy). *If $x < y$ then either*
(a) $\omega(x) < \omega(y)$, *or*
(b) $\omega(x) = \omega(y) \subset E$.
If case (b) *holds and $t_k \to \infty$ then $\Phi_{t_k}(x) \to p$ if and only if $\Phi_{t_k}(y) \to p$.*

PROOF. If $\omega(x) = \omega(y)$ then $\omega(x) \subset E$ by the Intersection Principle, Theorem 1.12, which also establishes the final assertion. If $\omega(x) \neq \omega(y)$ then we may assume that there exists $q \in \omega(y) \setminus \omega(x)$, the other case being similar. There exists $t_k \to \infty$ such that $\Phi_{t_k}(y) \to q$. By passing to a subsequence if necessary, we can assume that $\Phi_{t_k}(x) \to p \in \omega(x)$. Monotonicity implies $p \leqslant q$ and, in fact, $p < q$ since $q \notin \omega(x)$. By the Limit Set Separation Principle, $\omega(x) < \omega(y)$. ☐

Among the many consequences of the Convergence Criterion is that a monotone semiflow in a strongly ordered Banach space cannot have a periodic orbit γ that is *attracting*, meaning that γ attracts all points in some neighborhood of itself (Hadeler [55], Hirsch [69]). The following consequence of the Limit Set Dichotomy implies the same conclusion for periodic orbits of SOP semiflows:

THEOREM 1.17. *Let γ be a nontrivial periodic orbit, some point of which is accessible from above or below. Then γ is not attracting.*

The accessibility hypothesis is used to ensure that there are points near p that are order-related to p but different from p. Some such hypothesis is required, as otherwise we could simply take $X = \gamma$, and then γ is attracting!

PROOF. Suppose $\gamma \subset W$ attracts an open set W. By hypothesis there exists $p \in \gamma$ and $x \in W$ such that $x > p$ or $x < p$ and $\omega(x) = \gamma$. To fix ideas we assume $x > p$. Then

$p \in \omega(x)$, so the Limit Set Dichotomy implies $p \in E$. Hence the contradiction that γ contains an equilibrium. □

It turns out that the periodic orbits γ considered above are not only not attracting; they enjoy the strong form of instability expressed in the next theorem.

A set $K \subset X$ is *minimal* if it is nonempty, invariant, and every orbit it contains is dense in K.

THEOREM 1.18. *Let K be a compact minimal set that is not an equilibrium, some point of which is accessible from below or above. Then there exists $\delta > 0$ with the following property*: *Every neighborhood of K contains a point x comparable to some point of K, such that* $\operatorname{dist}(\Phi_t(x), K) > \delta$ *for all sufficiently large t.*

PROOF. We may assume there exists a sequence $\tilde{x}_n \to p \in K$ with $\tilde{x}_n > p$. Suppose there is no such δ. Then there exist a subsequence $\{x_n\}$ and points $y_n \in \omega(x_n)$ such that $y_n \to q \in K$. Minimality of K implies $\omega(p) = \omega(q) = K$. Since $x_n > p$, the Limit Set Dichotomy implies $\omega(x_n) \geqslant \omega(p)$; therefore $y_n \geqslant K$, so $q \geqslant K$. It follows that $q = \sup K$, and Corollary 1.9 implies the contradiction that K is a singleton. □

A stronger form of instability for periodic orbits is given in Theorem 2.6.

1.5. *Q is plentiful*

One of our main goals is to find conditions that make quasiconvergent points generic in various senses. The first such results are due to Hirsch [66,73]; the result below is an adaptation of Smith and Thieme [199, Theorem 3.5].

We continue to assume Φ is an SOP semiflow with compact orbit closures.

A *totally ordered arc* is the homeomorphic image of a nontrivial interval $I \subset \mathbb{R}$ under a map $f : I \to X$ satisfying $f(s) < f(t)$ whenever $s, t \in I$ and $s < t$.

THEOREM 1.19. *If $J \subset X$ is a totally ordered arc, $J \setminus Q$ is at most countable.*

Stronger conclusions are obtained in Theorems 2.8 and 2.24.

The following global convergence theorem is adapted from Hirsch [73, Theorem 10.3].

COROLLARY 1.20. *Let Y be an ordered Banach space. Assume $X \subset Y$ is an open set, a closed order interval, or a subcone of Y_+. If $E = \{p\}$, every trajectory converges to p.*

PROOF. If X is open in Y, there exists a totally ordered line segment $J \subset X$ and quasiconvergent points $u, v \in J$ with $u < x < v$, by Theorem 1.19. Therefore $\Phi_t(u) \to p$ and $\Phi_t(v) \to p$, so monotonicity and closedness of the order relation imply $\Phi_t(x) \to p$.

If $X = [a, b]$, the trajectories of a and b converge to p by the Convergence Criterion 1.4, and the previous argument shows all trajectories converge to p. Similarly if X is a subcone of Y_+. □

PROOF OF THEOREM 1.19. Let $W = \overline{\Phi([0,\infty) \times J)}$. Continuity of Φ implies that W is a separable metric space which is positively invariant under Φ. Therefore we may as well assume that X is a separable metric space.

We show that if $x \in J$ and

$$\inf\bigl\{\operatorname{dist}\bigl(\omega(x), \omega(y)\bigr)\colon\ y \in J, y \neq x\bigr\} = 0,$$

then $x \in Q$. Choose a sequence $x_n \in J$, $x_n \neq x$ such that $\operatorname{dist}(\omega(x), \omega(x_n)) \to 0$. We may assume that $x_n < x$ for all n. Taking a subsequence, we conclude from the Limit Set Dichotomy: Either some $\omega(x_n) = \omega(x)$, or every $\omega(x_n) < \omega(x)$.

In the first case, $x \in Q$. In the second case, choose $y_n \in \omega(x_n)$, $z_n \in \omega(x)$ such that $d(y_n, z_n) \to 0$. After passing to subsequences, we assume $y_n, z_n \to z \in \omega(x)$. Because $y_n \leqslant \omega(x)$, we conclude that $z \leqslant \omega(x)$. As $z \in \omega(x)$, Corollary 1.9 implies $\omega(x) = \{z\}$. Hence $x \in Q$ in this case as well.

It follows that for every $x \in J \setminus Q$, there exists an open set U_x containing $\omega(x)$ such that $U_x \cap \omega(y) = \emptyset$ for every $y \in J \setminus \{x\}$. By the axiom of choice we get an injective mapping

$$J \setminus Q \to X, \quad x \mapsto p_x \in \omega(x) \subset U_x.$$

The separable metric space X has a countable base $\mathcal{B}$. A second application of the axiom of choice gives a map

$$J \setminus Q \to \mathcal{B}, \quad x \mapsto V_x \subset U_x, \quad p_x \in V_x.$$

This map is injective. For if x, y are distinct points of $J \setminus Q$, then $V_x \neq V_y$ because V_x, being contained in U_x, does not meet $\omega(y)$; but $p_y \in V_y \cap \omega(y)$. This proves $J \setminus Q$ is countable. □

Let Y be an ordered Banach space and assume $X \subset Y$ is an ordered subspace (not necessarily linear). When Y is finite-dimensional, Theorem 1.19 implies $X \setminus Q$ has Lebesgue measure zero, hence almost every point is quasiconvergent. For infinite-dimensional Y there is an analogous result for Gaussian measures (Hirsch [73, Lemma 7.7]). The next result shows that in this case Q is also plentiful in the sense of category.

A subset of a topological space S is *residual* if it contains the intersection of countably many dense open subsets of S. When S is a complete metric space every residual set is dense by the Baire category theorem.

The assumption on X in the following result holds for many subsets of an ordered Banach space, including all convex sets and all sets with dense interior.

THEOREM 1.21. *Assume X is a subset of an ordered Banach space Y, and a dense open subset $X_0 \subset X$ is covered by totally ordered line segments. Then Q is residual in X.*

PROOF. It suffices to show that the set $Q_1 := Q \cup (Y \setminus X_0)$ is residual in Y. Note that $Y \setminus Q_1 = X_0 \setminus Q$. Let $L \subset Y$ be the 1-dimensional space spanned by some positive vector. Every translate $y + L$ meets $Y \setminus Q_1$ in a finite or countably infinite set by Theorem 1.19, hence $(y + L) \cap Q_1$ is residual in the line $y + L$. By the Hahn–Banach theorem there is a closed linear subspace $M \subset Y$ and a continuous linear isomorphism $F\colon Y \approx M \times L$ such that $F(x + L) = \{x\} \times L$ for each $x \in M$. Therefore $F(Q_1) \cap (\{x\} \times L)$ is residual in $\{x\} \times L$ for all $x \in X_0$, whence $F(Q_1)$ is residual in $M \times L$ by the Kuratowski–Ulam Theorem (Oxtoby [154]). This implies Q_1 is residual in Y. □

Additional hypotheses seem to be necessary in order to prove density of Q in general ordered spaces. The next theorem obtains the stronger conclusion that Q has dense interior. A different approach will be explored in Section 2.

A point x is *doubly accessible from below* (respectively, above) if in every neighborhood of x there exist f, g with $f < g < x$ (respectively, $x < f < g$).

Consider the following condition on a semiflow satisfying (H):

(L) Either every omega limit set has an infimum in X and the set of points that are doubly accessible from below has dense interior, or every omega limit set has a supremum in X and the set of points that are doubly accessible from above has dense interior.

This holds when X is the Banach space of continuous functions on a compact set with the usual ordering, for then every compact set has a supremum and infimum, and every point is doubly accessible from above and below.

THEOREM 1.22. *If* (L) *holds, then* $X \setminus Q \subset \overline{\operatorname{Int} C}$, *and* $\operatorname{Int} Q$ *is dense.*

The proof is based on the following result. For $p \in E$ define $C(p) := \{z \in X\colon \omega(z) = \{p\}\}$. Note that $C = \bigcup_{p \in E} C(p)$.

LEMMA 1.23. *Suppose* $x \in X \setminus Q$ *and* $a = \inf \omega(x)$. *Then* $\omega(a) = \{p\}$ *with* $p < \omega(x)$, *and* $x \in \overline{\operatorname{Int} C(p)}$ *provided* x *is doubly accessible from below.*

PROOF. Fix an arbitrary neighborhood M of x. Note that $a < \omega(x)$ because $\omega(x)$ is unordered (Theorem 1.8). By invariance of $\omega(x)$ we have $\Phi_t a \leqslant \omega(x)$, hence $\Phi_t a \leqslant a$. Therefore the Convergence Criterion Theorem 1.4 implies $\omega(a)$ is an equilibrium $p \leqslant a$. Because $p < \omega(x)$, SOP yields a neighborhood N of $\omega(x)$ and $s \geqslant 0$ such that $p \leqslant \Phi_t N$ for all $t \geqslant s$. Choose $r \geqslant 0$ with $\Phi_t x \in N$ for $t \geqslant r$. Then $p \leqslant \Phi_t x$ if $t \geqslant r + s$. The set $V := (\Phi_{r+s})^{-1}(N) \cap M$ is a neighborhood of x in M with the property that $p \leqslant \Phi_t V$ for all $t \geqslant r + 2s$. Hence:

$$u \in V \quad \Longrightarrow \quad p \leqslant \omega(u). \tag{1.3}$$

Now assume x doubly accessible from below and fix $y_1, y \in V$ with $y_1 < y < x$. By the Limit Set Dichotomy $\omega(y) < \omega(x)$, because $\omega(x) \not\subset E$. By SOP we fix a neighborhood $U \subset V$ of y_1 and $t_0 > 0$ such that $\Phi_{t_0} u \leqslant \Phi_{t_0} y$ for all $u \in U$. The Limit Set Dichotomy implies $\omega(u) = \omega(y)$ or $\omega(u) < \omega(y)$; as $\omega(y) < \omega(x)$, we therefore have:

$$u \in U \quad \Longrightarrow \quad \omega(u) < \omega(x). \tag{1.4}$$

For all $u \in U$, (1.4) implies $\omega(u) \leqslant \omega(a) = \{p\}$, while (1.3) entails $p \leqslant \omega(u)$. Hence $U \subset C(p) \cap M$, and the conclusion follows. □

PROOF OF THEOREM 1.22. To fix ideas we assume the first alternative in (L), the other case being similar. Let X_0 denote a dense open set of points doubly accessible from below. Lemma 1.23 implies $X_0 \subset Q \cup \overline{\operatorname{Int} C} \subset Q \cup \overline{\operatorname{Int} Q}$, hence the open set $X_0 \setminus \overline{\operatorname{Int} Q}$ lies in Q. This prove $X_0 \setminus \overline{\operatorname{Int} Q} \subset \operatorname{Int} Q$, so $X_0 \setminus \overline{\operatorname{Int} Q} = \emptyset$. Therefore $\overline{\operatorname{Int} Q} \supset X_0$, hence $\overline{\operatorname{Int} Q} \supset \overline{X_0} = X$. □

EXAMPLE 1.24. An example in Hirsch [73] shows that generic quasiconvergence and the Limit Set Dichotomy need not hold for a monotone semiflow that does not satisfy SOP. Let X denote the ordered Banach space $\mathbb{R}^3$ whose ordering is defined by the “ice-cream” cone $X_+ = \{x \in \mathbb{R}^3\colon\ x_3 \geqslant \sqrt{x_1^2 + x_2^2}\}$. The linear system $x_1' = -x_2,\ x_2' = x_1,\ x_3' = 0$ generates a flow Φ with global period 2π which merely rotates points about the x_3-axis. Evidently X_+ is invariant, so linearity of Φ implies monotonicity. On the other hand, Φ is not strongly order preserving: If $a = (1, 0, 1)$ (or any other point on ∂Y_+ except the origin 0), SOP would require $\Phi_t(a) \gg 0$ for $t > 0$ because Φ_t is a homeomorphism, but this fails for all $t > 0$. The Limit Set Dichotomy fails to hold: For $a = (1, 0, 1)$ and $b = (2, 0, 2)$ it is easy to see that $a < b$ (for the ordering defined by X_+) and $\omega(a) \cap \omega(b) = \emptyset$, but $\omega(a) \not< \omega(b)$. As $E = C = Q = \{x\colon\ x_1 = x_2 = 0\}$ and most points belonging to periodic orbits of minimal period 2π, quasiconvergence is rare. In fact, the set of nonquasiconvergent points—the complement of the x_3-axis—is open and dense. It is not known whether there is a similar example with a polyhedral cone.

1.6. *Stability in normally ordered spaces*

We continue to assume the semiflow Φ is SOP with compact orbit closures.

The *diameter* of a set Z is $\operatorname{diam} Z := \sup_{x,y\in Z} d(x, y)$.

We now introduce some familiar stability notions. A point $x \in X$ is *stable* (relative to $R \subset X$) if for every $\epsilon > 0$ there exists a neighborhood U of x such that $\operatorname{diam} \Phi_t(U \cap R) < \epsilon$ for all $t \geqslant 0$. The set of stable points is denoted by S.

Suppose x_0 is stable. Then omega limit sets of nearby points are close to $\omega(x_0)$, and if all orbit closures are compact, the map $x \mapsto \omega(x)$ is continuous at x_0 for the Hausdorff metric on the space of compact sets.

x is *stable from above* (respectively, *from below*) if x is stable relative to the set of points $\geqslant x$ (resp., $\leqslant x$). The set of points stable from above (resp., below is denoted by S_+ (resp., S_-).

The *basin of* x in R is the union of all subsets of R of the form $V \cap R$ where $V \subset X$ is an open neighborhood of x such that

$$\lim_{t\to\infty} \operatorname{diam} \Phi_t(V \cap R) = 0.$$

Notice that $\omega(x) = \omega(y)$ for all y in the basin.

If the basin of x in R is nonempty, we say x is *asymptotically stable* relative to R. This implies x is stable relative to R. If x is asymptotically stable relative to X we say x is *asymptotically stable*. The set of asymptotically stable points is an open set denoted by A.

x is *asymptotically stable from above* (respectively, *below)* if it is asymptotically stable relative to the set of points $\geqslant x$ (resp., $\leqslant x$). The basin of x relative to this set is called the *upper* (resp., *lower*) basin of x. The set of such x is denoted by A_+ (resp., A_-).

Note that continuity of Φ shows that asymptotic stability relative to R implies stability relative to R. In particular, $A \subset S$, $A_+ \subset S_+$ and $A_- \subset S_-$.

These stability notions for x depend only on the topology of X, and not on the metric, provided the orbit of x has compact closure.

The metric space X is *normally ordered* if there exists a *normality constant* $\kappa > 0$ such that $d(x, y) \leqslant \kappa d(u, v)$ whenever $u, v \in X$ and $x, y \in [u, v]$. In a normally ordered space order intervals are bounded and the diameter of $[u, v]$ goes to zero with $d(u, v)$. Many common function spaces, including L^p spaces and the Banach space of continuous functions with the uniform norm, are normally ordered by the cone of nonnegative functions. But spaces whose norms involve derivatives are not normally ordered. Normality is required in order to wring the most out of the Sequential Limit Set Trichotomy. The propositions that follow record useful stability properties of SOP dynamics in normally ordered spaces.

PROPOSITION 1.25. *Assume X is normally ordered.*

(a) *$x \in S_+$ (respectively, S_-) provided there exists a sequence $y_n \to x$ such that $y_n > x$ (resp., $y_n < x$) and* $\lim_{n\to\infty} \sup_{t>0} d(\Phi_t(x), \Phi_t(y_n)) = 0$.

(b) *$x \in S$ provided $x \in S_+ \cap S_-$ and x is accessible from above and below.*

(c) *$x \in A$ provided $x \in A_+ \cap A_-$ and x is accessible from above and below.*

(d) *Suppose $a < b$ and $\omega(a) = \omega(b)$. Then $a \in A_+$ and $b \in A_-$. If $a < x < b$ then $x \in A$ and the basin of x includes $[a, b] \setminus \{a, b\}$.*

In particular, (d) shows that an equilibrium e is in A_+ if $x > e$ and $\Phi_t(x) \to e$ (provided X is normally ordered); and dually for A_-.

PROOF. We prove (a) for the case $y_n > x$. Given $\epsilon > 0$, choose m and t_0 so that

$$t > t_0 \implies d\big(\Phi_t(x), \Phi_t(y_m)\big) < \epsilon.$$

By SOP there exists a neighborhood W of x and $t_1 > t_0$ such that

$$t > t_1,\ v \in W \implies \Phi_t(v) < \Phi_t(y_m).$$

Fixing t_1, we shrink W to a neighborhood W_ϵ of x so that

$$0 < t \leqslant t_1,\ v \in W_\epsilon \implies d\big(\Phi_t(x), \Phi_t(v)\big) < \kappa\epsilon,$$

where $\kappa > 0$ is the normality constant. If $x < v \in W_\epsilon$ and $t > t_1$ then $\Phi_t(x) \leqslant \Phi_t(v) \leqslant \Phi_t(y_m)$, and therefore

$$t > t_1,\ x < v \in W_\epsilon \implies d\big(\Phi_t(x), \Phi_t(v)\big) \leqslant \kappa d\big(\Phi_t(x), \Phi_t(y_m)\big) \leqslant \kappa\epsilon.$$

Hence we have proved

$$0 < t < \infty,\ v \in W_\epsilon \quad \Longrightarrow \quad d\big(\Phi_t(x), \Phi_t(v)\big) < \kappa\epsilon.$$

As ϵ is arbitrary, this proves $x \in S_+$.

To prove (b), let $u_n, v_n \to x$ with $u_n < x < v_n$. Because $x \in S_+ \cap S_-$, for any $\epsilon > 0$ there exists $\delta > 0$ such that if $d(y, x) < \delta$ and $y < x$ or $y > x$, then $\sup_{t>0} d(\Phi_t(y), \Phi_t(x)) < \epsilon$. Choose k such that $d(u_k, x) < \delta$ and $d(v_k, x) < \delta$. By SOP there is a neighborhood W_ϵ of x such that $\Phi_t(u_k) \leqslant \Phi_t(W_\epsilon) \leqslant \Phi_t(v_k)$ for sufficiently large t. Normality implies that for such t,

$$\begin{aligned}\kappa^{-1} \operatorname{diam} \Phi_t(W_e) &\leqslant d\big(\Phi_t(u_k), \Phi_t(v_k)\big)\\ &\leqslant d\big(\Phi_t(u_k), \Phi_t(x)\big) + d\big(\Phi_t(x), \Phi_t(v_k)\big) < 2\epsilon.\end{aligned}$$

As κ is constant and ϵ is arbitrary, this proves x is stable.

The proofs of (c) and (d) are similar. □

PROPOSITION 1.26. *Assume X is normally ordered, $p \in E$, and $\{K_n\}$ is a sequence of nonempty compact invariant sets such that $K_n < p$ and* $\operatorname{dist}(K_n, p) \to 0$. *Then*:

(a) *p is stable from below.*

(b) *If z is such that $\omega(z) = p$, then z is stable from below.*

In particular, if p is the limit of a sequence of equilibria $< p$ then p is stable from below.

PROOF. (a) Given $\epsilon > 0$, fix m such that $\operatorname{dist}(K_m, p) < \epsilon$. By Lemma 1.3 there is a neighborhood W of p and $t_0 > 0$ such that $t > t_0 \Longrightarrow \Phi_t(W) \geqslant K_m$, and therefore

$$t > t_0,\ v \in W,\ p > v \quad \Longrightarrow \quad d\big(\Phi_t(p), \Phi_t(v)\big) \leqslant \kappa d\big(\Phi_t(p), \Phi_t(K_m)\big) \leqslant \kappa\epsilon.$$

Pick a neighborhood $W_\epsilon \subset W$ of p so small that

$$0 \leqslant t \leqslant t_0,\ v \in W_\epsilon \quad \Longrightarrow \quad d\big(\Phi_t(p), \Phi_t(v)\big) < \kappa\epsilon.$$

Then

$$0 \leqslant t < \infty,\ v \in W_\epsilon,\ v < p \quad \Longrightarrow \quad d\big(\Phi_t(p), \Phi_t(v)\big) < \kappa\epsilon.$$

This proves $p \in S_-$, because ϵ is arbitrary.

(b) Choose a neighborhood U of z and $t_1 \geqslant 0$ such that $\Phi_{t_1}(U) \subset W$. Assume $y \in U$, $y < z$. If $t \geqslant t_1 + t_0$, then $K_m \leqslant \Phi_t(y) \leqslant \Phi_t(z)$, and therefore by normality, $d(\Phi_t(y), \Phi_t(z)) \leqslant \kappa \operatorname{dist}(K_m, \Phi_t(z))$. As $\Phi_t(z) \to p$, there exists $t_2 \geqslant t_1 + t_0$ such that

$$t \geqslant t_2 \quad \Longrightarrow \quad d\big(\Phi_t(y), \Phi_t(z)\big) \leqslant \kappa \operatorname{dist}(K_m, p) < \kappa\epsilon.$$

Fix this t_2. By continuity of Φ there is a neighborhood $U_1 \subset U$ of z so small that

$$0 \leqslant t \leqslant t_2 \implies d\big(\Phi_t(y), \Phi_t(z)\big) \leqslant \kappa\epsilon.$$

As ϵ is arbitrary, this implies $z \in S_-$. □

1.7. *Stable equilibria in strongly ordered Banach spaces*

In spaces that are not normally ordered we cannot directly use the results of the previous subsection to characterize stable equilibria. For strongly monotone semiflows in strongly ordered Banach spaces we work around this by introducing a weaker norm that makes the order normal, and for which the semiflows are continuous and SOP. This permits use of the earlier results.

Let Y be a strongly ordered Banach space. The *order topology* on Y is the topology generated by open order intervals. An *order norm* on the topological vector space $\widehat{Y}$ is defined by fixing $u \gg 0$ and assigning to x the smallest ϵ such that $x \in [-\epsilon u, \epsilon u]$. It is easy to see that $\widehat{Y}$ is normally ordered by the order norm, with normality constant 1. Every order neighborhood of p in $\widehat{Y}$ contains $[p - \epsilon u, p + \epsilon u]$ for all sufficiently small numbers $\epsilon > 0$. For example, $Y = C^1([0, 1])$ with the usual C^1-norm and with Y_+ the cone of nonnegative functions is strongly ordered but not normally ordered; putting $u := 1$, the order norm becomes the usual supremum.

The induced topology on any subset $Z \subset Y$ is also referred to as the order topology, and the resulting topological space is denoted by $\widehat{Z}$. A neighborhood in $\widehat{Z}$ is an *order neighborhood*.

Every open subset of $\widehat{Z}$ is open in Z, i.e., the identity map of Z is continuous from Z to $\widehat{Z}$. Therefore $\widehat{Z} = Z$ as topological spaces when Z is compact. As shown below, if Ψ is a monotone local semiflow in Z, it is also a local semiflow in $\widehat{Z}$, denoted by $\widehat{\Psi}$. Evidently Ψ and $\widehat{\Psi}$ have the same orbits and the same invariant sets.

LEMMA 1.27. *Let Ψ be a monotone local semiflow in a subset X of a strongly ordered Banach space Y, that extends to a monotone local semiflow in an open subset of Y. Then*:

(a) *$\widehat{\Psi}$ is a monotone local semiflow.*

(b) *If Ψ is a strongly monotone, then $\widehat{\Psi}$ is SOP.*

PROOF. It suffices to prove (a) and (b) when X is open in Y, which condition is henceforth assumed.

$\widehat{\Psi}$ is monotone because Ψ is monotone. To prove continuity of $\widehat{\Psi}$, let $N = [[a, b]]_Y \cap X$ and $(t_0, x_0) \in \widehat{\Psi}^{-1}(N)$. As the latter is open in $\mathbb{R}_+ \times X$, there exists $\epsilon > 0$ and U, an open neighborhood of x_0 in X, such that

$$\big[(t_0 - \epsilon, t_0 + \epsilon) \cap \mathbb{R}_+\big] \times U \subset \widehat{\Psi}^{-1}(N).$$

We may choose $u, v \in U$ such that $x \in [[u, v]]_Y$. If $z \in [[u, v]]_Y \cap X$ and $|t - t_0| < \epsilon$ then by monotonicity and $u, v \in U$ we have $a \ll \widehat{\Psi}_t(u) \leqslant \widehat{\Psi}_t(z) \leqslant \widehat{\Psi}_t(v) \ll b$. Thus,

$$\big[(t_0 - \epsilon, t_0 + \epsilon) \cap \mathbb{R}_+\big] \times \big([[u, v]]_Y \cap X\big) \subset \widehat{\Psi}^{-1}(N),$$

proving the continuity of $\widehat{\Psi}$.

Assume $x, y \in X$, $x < y$ and let $t_0 > 0$ be given. By strong monotonicity of Ψ there are respective open neighborhoods $U, V \subset X$ of x, y such that $\Psi_{t_0}(U) \leqslant \Psi_{t_0}(V)$ (see Proposition 1.2). Choose $w, u, v, z \in X$ such that $u, w \in U$, $v, z \in V$ and

$$w \ll x \ll u, \qquad v \ll y \ll z$$

so that $[[w, u]]_Y \cap X$ and $[[v, z]]_Y \cap X$ are order neighborhoods in X of x, y respectively. Monotonicity of Ψ implies

$$\Psi_{t_0}\big([[w, u]]_Y \cap X\big) \leqslant \Psi_{t_0}\big([[v, z]]_Y \cap X\big). \qquad \square$$

An equilibrium p for $\Psi : \mathbb{R}^+ \times X \to X$ is *order stable* (respectively, *asymptotically order stable* if p is stable (respectively, asymptotically stable) for $\widehat{\Psi}$.

PROPOSITION 1.28. *Let Ψ be a monotone local semiflow in a subset X of a strongly ordered Banach space Y, that extends to a monotone local semiflow in some open subset of Y. Assume p is an equilibrium having a neighborhood W that is attracted to a compact set $K \subset X$. If p is order stable* (*respectively, asymptotically order stable*), *it is stable* (*respectively, asymptotically stable*).

PROOF. Suppose p is order stable and let U be a neighborhood of p. As $\widehat{K} = K$, there is a closed order neighborhood N_0 of p such that $N_0 \cap K \subset U \cap K$. By order stability there exists an order neighborhood N_1 of p such that $O(N_1) \subset N_0$. Compactness of $N_0 \cap K$ implies there is an open set $V \supset K$ there is an open set $V \supset K$ such that $N_0 \cap V \subset U$. Because K attracts W, there is a neighborhood $U_2 \subset W$ of p and $r \geqslant 0$ such that

$$t \geqslant r \quad \Longrightarrow \quad \Psi_t(U_2) \subset V.$$

By continuity of Ψ_r at $p = \Psi_r(p)$ there is a neighborhood $U_3 \subset U_2$ of p such that

$$0 \leqslant t \leqslant r \quad \Longrightarrow \quad \Psi_t(U_3) \subset V.$$

and thus $O(U_3) \subset V$. Therefore $N_1 \cap U_3$ is a neighborhood of p such that

$$O(N_1 \cap U_3) \subset O(N_1) \cap O(U_3) \subset N_0 \cap V \subset U.$$

This shows p is stable.

Assume p is asymptotically order stable and choose an order neighborhood $M \subset X$ of p that is attracted to p by $\widehat{\Psi}$. We show that $M \cap W$ is in the basin of p for Ψ. Consider arbitrary sequences $\{x_k\}$ in $M \cap W$ and $t_k \to \infty$ in $[0, \infty)$. Fix $u \gg 0$. By the choice of M there are positive numbers $\epsilon_k \to 0$ such that

$$p - \epsilon_k u \ll \Psi_{t_k}(x_k) \ll p + \epsilon_k u.$$

This implies $\Psi_{t_k}(x_k) \to p$ in X, because the order relation on X is closed and $\{\Psi_{t_k}(x_k)\}$ is precompact in X by the choice of W and compactness of K. $\square$

1.8. *The search for stable equilibria*

The following results illustrate the usefulness of a dense set of quasiconvergent points. Φ denotes a strongly order preserving semiflow in X; Hypothesis (H) of Section 1.4 is still in force.

PROPOSITION 1.29. *Assume Q is dense. Let $p, q \in E$ be such that $p < q$, p is accessible from above, and q is accessible from below. Then there exists $z \in X$ satisfying one of the following conditions*:

(a) $p < z < q$, *and* $\Phi_t(z) \to p$ *or* $\Phi_t(z) \to q$;

(b) $p < z < q$ *and* $z \in E$;

(c) $z > p$ *and* $p \in O(z)$, *or* $z < q$ *and* $q \in O(z)$.

PROOF. By SOP there are open neighborhoods U, V of p, q respectively and $t_0 \geqslant 0$ such that $\Phi_t U \leqslant \Phi_t V$ for $t \geqslant t_0$. Choose sequences $x_n \to p$ in U and $y_n \to q$ in V with $p < x_n$, $y_n < q$. We assume $p \notin O(x_n)$ and $q \notin O(y_n))$, as otherwise (c) is satisfied. Then

$$t \geqslant t_0 \quad \Longrightarrow \quad p < \Phi_t(x_n) \leqslant \Phi_t(y_n) < q.$$

Choose open neighborhoods U_1, W, V_1 of $p, \Phi_{t_0}(y_1), q$ respectively such that for some $t_1 \geqslant t_0$:

$$t \geqslant t_1 \quad \Longrightarrow \quad \Phi_t(U_1) \leqslant \Phi_t(W) \leqslant \Phi_t(V_1).$$

Choose $w \in Q \cap W$ and a sequence $s_k \to \infty$, $s_k \geqslant t_1$ such that $\Phi_{s_k}(w) \to e \in E$. Fix m so large that $x_m \in U_1$, $y_m \in V_1$. Then for sufficiently large k,

$$p < \Phi_{s_k}(x_m) \leqslant \Phi_{s_k}(w) \leqslant \Phi_{s_k}(y_m) < q.$$

It follows that $p \leqslant e \leqslant q$. If $e = p$ or q then $\omega(\Phi_{s_k}(w)) = p$ or q by the Convergence Criterion 1.4, giving (a) with $z = \Phi_{s_k}(w)$. Therefore if (a) does not hold, (b) holds with $z = e$. □

The assumption in Proposition 1.29 that Q is dense can be considerably weakened, for example, to p (or q) being interior to $\overline{Q}$: Assume $y_1 \in \overline{\operatorname{Int} Q}$ and set $w = \Phi_{s_k}(w_0)$, $w_0 \in (\operatorname{Int} Q) \cap \Phi_{s_k}{}^{-1}(W)$, etc. In fact, density of Q can be replaced with the assumption that p or q lies in the interior of the set $Q_\#$ of points x such that there is a sequence $x_i \to x$ with $\lim_{i\to\infty} \operatorname{dist}(\omega(x_i), E) = 0$. Clearly $Q_\#$ is closed and contains Q, so density of Q implies $Q_\# = X$.

THEOREM 1.30. *Suppose X is normally ordered and the following three conditions hold*:

(a) *Q is dense*;

(b) *if $e \in E$ and e is not accessible from above* (*below*) *then $e = \sup X$* ($e = \inf X$);

(c) *there is a maximal totally ordered subset $R \subset E$ that is nonempty and compact.*

Then R contains a stable equilibrium, an asymptotically stable equilibrium if R is finite.

PROOF. By Lemma 1.1, $\sup R$ ($\inf R$) exists and is a maximal (minimal) element of E. We first prove that every maximal equilibrium q is in A_+. This holds vacuously when $q = \sup X$. Suppose $q \neq \sup X$. If q is in the orbit of some point $> q$ then $q \in A_+$ by Proposition 1.25(d). Hence we can assume:

$$t \geqslant 0,\ y > q \quad \Longrightarrow \quad \Phi_t(y) > q.$$

By hypothesis we can choose $y > q$. By SOP there is an open neighborhood U of q and $s > 0$ such that $\Phi_s(y) \geqslant \Phi_s(U)$. By hypothesis we can choose $z \in U$ such that $\Phi_s(y) \neq \Phi_s(z)$ and $z > q$. Set $x_2 = \Phi_s(y)$, $x_1 = \Phi_s z$. Then $x_2 > x_1 > q$, By SOP and the assumption above there is a neighborhood V_2 of x_2 and $t_0 \geqslant 0$ such that

$$t > t_0 \quad \Longrightarrow \quad q < \Phi_t(x_1) \leqslant \Phi_t(V_2).$$

Choose $v \in V_2 \cap Q$. Then $q < \Phi_t(v)$ for $t \geqslant t_0$, hence $q \leqslant \omega(v) = \omega(\Phi_{t_0}(v)) \subset E$. Therefore $\Phi_t(v) \to q$ by maximality of q, so and Proposition 1.25(d) implies $q \in A_+$, as required. The dual argument shows that every minimal equilibria is in A_-.

Assumption (c) and previous arguments establish that $q = \sup R$ and $p = \inf R$ satisfy $p \leqslant q$ and $q \in A_+$, $p \in A_-$.

Suppose $p = q$; in this case we prove $q \in A$. As q is both maximal and minimal in E, we have $q \in A_+ \cap A_-$. If q is accessible from above and below then $q \in A$ by Proposition 1.25(b). If q is not accessible from above then by hypothesis $q = \sup X$, in which case the fact that $q \in A_-$ implies $q \in A$. Similarly, $q \in A$ if q is not accessible from below.

Henceforth we assume $p < q$. As R is compact and $R \cap S_- \neq \emptyset$ because $p \in R$, it follows that R contains the equilibrium $r := \sup(R \cap S_-)$. Note that $r \in S_-$, because this holds by definition of r if r is isolated in $\{r' \in R\colon r' \leqslant r\}$, and otherwise $r \in S_-$ by Proposition 1.26(a). If $r = q$ a modification of the preceding paragraph proves $q \in S$.

Henceforth we assume $r < q$; therefore r is accessible from above.

If r is not accessible from below then $r = p = \inf X$ so $r \in S$ and we are done; so we may as well assume r is accessible from below as well as from above. If r is the limit of a sequence of equilibria $> r$ then $r \in S_+$ by the dual of Proposition 1.26, hence $r \in S$ by Proposition 1.25(b). Therefore we can assume R contains a smallest equilibrium $r_1 > r$. Note that $r_1 \notin S_-$ by maximality of r. We apply Proposition 1.29 to r, r_1: among its conclusions, the only one possible here is that $z > r$ and $\Phi_t(z) \to r$ (and perhaps $r \in O(z)$). Therefore $r \in S_+$ by Proposition 1.25(a), whence $r \in S$ by 1.25(b). When R is finite, a modification of the preceding arguments proves $\max(R \cap A_-) \subset A$. □

Assumption (b) in the Theorem 1.30 holds for many subsets X of an ordered Banach space Y, including open sets, subcones of Y_+, closed order intervals, and so forth. This result is similar to Theorem 10.2 of Hirsch [73], which establishes equilibria that are merely order stable, but does not require normality.

Assumption (c) holds when E is compact, and also in the following situation: $X \subset Y$ where Y is an L^p space, $1 \leqslant p < \infty$, and E is a nonempty, closed, and order bounded subset of X; then every order bounded increasing or decreasing sequence converges. If (c) holds and some Φ_t is real analytic with spatial derivatives that are compact and strongly positive operators, then R is finite. This follows from the statements and proofs of Lemma 3.3 and Theorem 2 in Jiang and Yu [90].

For related results on stable equilibria see Jiang [86], Mierczyński [138,139], and Hirsch [69].

THEOREM 1.31. *Let Φ be a semiflow in a subset X of a strongly ordered Banach space Y, that extends to a strongly monotone local semiflow in some open subset of Y. Assume hypotheses* (a), (b), (c) *of Theorem* 1.30 *hold, and every equilibrium has a neighborhood attracted to a compact set. Let $R \subset E$ be as in* 1.30(c). *Then R contains a stable equilibrium, and an asymptotically stable equilibrium when R is finite.*

PROOF. Our strategy is to apply Theorem 1.30 to the semiflow $\widehat{\Phi}$ in $\widehat{X}$ (see Section 1.7). Give $\widehat{X}$ the metric coming from an order norm on $\widehat{Y}$; this makes $\widehat{X}$ is normally ordered. Lemma 1.27 shows that $\widehat{\Phi}$ is SOP. Therefore R contains an equilibrium p that is stable for $\widehat{\Phi}$, by Theorem 1.30. This means p is order stable for Φ, whence Proposition 1.28 shows that p is stable for Φ. The final assertion follows similarly. ☐

Stable equilibria are found under various assumptions in Theorems 2.9, 2.10, 2.11, 2.26, 3.14, 4.12.

2. Generic convergence and stability

2.1. *The sequential limit set trichotomy*

Throughout Section 2 we assume Hypothesis (H) of Section 1.4:

> *Φ is a strongly order preserving semiflow in an ordered space X, with all orbit closures compact.*

The main result is that the typical orbit of an SOP semiflow is stable and approaches the set E of equilibria. Existence of stable equilibria is established under additional compactness assumptions.

The index n runs through the positive integers.

A point x is *strongly accessible from below* (*respectively*, above) if there exists a sequence $\{y_n\}$ converging to x such that $y_n < y_{n+1} < x$ (resp., $y_n > y_{n+1} > x$). In this case we say $\{y_n\}$ *strongly approximates x from below* (resp., *from above*).

The sequence $\{x_n\}$ is *omega compact* if $\bigcup_n \omega(x_n)$ is compact.

Define sets $BC, AC \subset X$ as follows:

$x \in BC \iff x$ is strongly accessible from below by an omega compact sequence,

$x \in AC \iff x$ is strongly accessible from above by an omega compact sequence.

In this notation “B” stands for “below,” “A” for above, and “C” for “compact.”

We will also use the following condition on a set $W \subset X$:

(C) Every sequence $\{w_n\}$ in W that strongly approximates a point of W from below or above is omega compact.

This does not assert that any point is strongly accessible from below or above. But if every point of W is accessible from above and W satisfies (C), then $W \subset AC$; and similarly for BC.

The next two propositions imply properties stronger than (C). Recall that a map $f : X \to X$ is *completely continuous* provided $\overline{f(B)}$ is compact for every bounded set $B \subset X$; and f *conditionally completely continuous* provided $\overline{f(B)}$ is compact whenever B and $f(B)$ are bounded subsets of X.

The *orbit* of any set $B \subset X$ is $O(B) = \bigcup_t \Phi_t(B)$.

Proposition 2.1. *Assume the following two conditions*:

(a) *every compact set has a bounded orbit, and*

(b) Φ_s *is conditionally completely continuous for some* $s > 0$.

If $L \subset X$ *is compact, then* $\overline{\bigcup_{x\in L} \omega(x)}$ *is compact and this implies* X *has property* (C).

Proof. $O(L)$ is a bounded set by (a), and positively invariant, so (b) implies compactness of $\overline{\Phi_s(O(L))}$. As the latter set contains $\omega(x)$ for all $x \in L$, the first assertion is proved. The second assertion follows from precompactness of $\{x_n\}$. □

Proposition 2.2. *Assume* $W \subset X$ *has the following property*: *For every* $x \in W$ *there is a neighborhood* $U_x \subset X$ *and a compact set* M_x *that attracts every point in* U_x. *Then* $\overline{O(x)}$ *is compact for every* $x \in W$, *and* $\overline{\bigcup_{y\in U_x} \omega(y)}$ *is compact*. *If* $z_n \to x \in W$ *then* $\overline{\bigcup_n \omega(z_n)}$ *is compact, therefore* W *has property* (C).

Proof. It is easy to see that $\overline{O(x)}$ is compact and $\overline{\bigcup_{y\in U_x} \omega(y)}$ is compact because it lies in M_x. Fix $k \geqslant 0$ such that $z_n \in U_x$ for all $n \geqslant k$. Then

$$\overline{\bigcup_n \omega(z_n)} = \bigcup_{1\leqslant n\leqslant k} \omega(z_n) \cup M_x,$$

which is the union of finitely many compact sets, hence compact. Condition (C) follows trivially. □

The key to stronger results on generic quasiconvergence and stability is the following result of Smith and Thieme [197]:

Theorem 2.3 (Sequential Limit Set Trichotomy). *Let* $\{\tilde{x}_n\}$ *be an omega compact sequence strongly approximating* $z \in BC$ *from below. Then there is a subsequence* $\{x_n\}$ *such that exactly one of the following three conditions holds*:

(a) *There exists* $u_0 \in E$ *such that*

$$\omega(x_n) < \omega(x_{n+1}) < \omega(z) = \{u_0\}$$

and

$$\lim_{n\to\infty} \operatorname{dist}\bigl(\omega(x_n), u_0\bigr) = 0.$$

In this case $z \in C$.

(b) *There exists* $u_1 = \sup\{u \in E\colon\ u < \omega(z)\}$ *and*

$$\omega(x_n) = \{u_1\} < \omega(z).$$

In this case $z \in \overline{\operatorname{Int} C}$. *Moreover* z *has a neighborhood* W *such that if* $w \in W$, $w < z$ *then* $\Phi_t(w) \to u_1$ *and* $\Phi_t(w) > u_1$ *for sufficiently large* t.

(c) $\omega(x_n) = \omega(z) \subset E$.
In this case $z \in \overline{\operatorname{Int} Q}$. *Moreover* $\omega(w) = \omega(z) \subset E$ *for every* $w < z$ *sufficiently near* z.

Note that z is convergent in (a), and strongly accessible from below by convergent points in (b). In (c), z is quasiconvergent and strongly accessible from below by quasiconvergent points.

If $z \in AC$ there is an analogous dual result, obtained by reversing the order relation in X. Although we do not state it formally, we will use it below. If $z \in AC \cap BC$ then both results apply. See Proposition 3.6 in Smith and Thieme [197].

PROOF OF THEOREM 2.3. By the Limit Set Dichotomy 1.16, either there exists a positive integer j such that $\omega(\tilde{x}_n) = \omega(\tilde{x}_m)$ for all $m, n \geqslant j$, or else there exists a subsequence $\{\tilde{x}_{n_i}\}$ such that $\omega(\tilde{x}_{n_i}) < \omega(\tilde{x}_{n_{i+1}})$ for all i. Therefore there is a subsequence $\{x_n\}$ such that $\omega(x_n) < \omega(x_{n+1})$ for all n, or $\omega(x_n) = \omega(x_{n+1})$ for all n.

Case I: $\omega(x_n) < \omega(x_{n+1})$. We will see that (a) holds. The Limit Set Dichotomy 1.16 implies $\omega(x_n) \leqslant \omega(z)$. In fact, that $\omega(x_n) < \omega(z)$. Otherwise $\omega(x_k) \cap \omega(z) \neq \emptyset$ for some k, and the Limit Set Dichotomy implies the contradiction $\omega(x_k) = \omega(z) \geqslant \omega(x_{k+1}) > \omega(x_k)$.

Define $K = \overline{\bigcup \omega(x_n)}$, a nonempty compact invariant set. Consider the set

$$\Lambda = \Bigl\{y\colon\ y = \lim_{n\to\infty} y_n,\ \ y_n \in \omega(x_n)\Bigr\} \subset K.$$

Clearly Λ is invariant and closed, and compactness of K implies Λ is compact and nonempty. We show that Λ is a single equilibrium. Suppose $y, v \in \Lambda$, so that $y_n \to y$, $v_n \to v$ with $y_n, v_n \in \omega(x_n)$. Since $y_n < v_{n+1}$ and $v_n < y_{n+1}$, we have $y \leqslant v$ and $v \leqslant y$, so $v = y$. Thus we can set $\Lambda = \{u_0\}$, and invariance implies $u_0 \in E$.

The definition of Λ and compactness of K imply $\lim_{n\to\infty} \operatorname{dist}(\omega(x_n), u_0) = 0$. From $\omega(x_n) < \omega(x_{n+1}) < \omega(z)$ we infer

$$\omega(x_n) < u_0 \leqslant \omega(z).$$

If $u_0 \in \omega(z)$ then $\omega(z) = \{u_0\}$ by Corollary 1.9, yielding (a).

We show that $u_0 < \omega(z)$ gives a contradiction. Choose a neighborhood W of $\omega(z)$ and $t_0 \geqslant 0$ such that $u_0 \leqslant \Phi_t(W)$ for all $t \geqslant t_0$ (by Lemma 1.3). There exists $t_1 > 0$ such that $\Phi_{t_1}(z) \in W$, and by continuity of Φ_{t_1} there exists m such that $\Phi_{t_1}(x_m) \in W$. It follows that $u_0 \leqslant \Phi_t(x_m)$ for $t \geqslant t_0 + t_1$. As $u_0 \in E$, we have $u_0 \leqslant \omega(x_m)$. But this contradicts $\omega(x_m) < u_0$. Thus (a) holds in Case I.

Case II: $\omega(x_n) = \omega(x_{n+1}) \subset E$. Since $x_n < z$, the Limit Set Dichotomy implies that either $\omega(x_n) = \omega(z)$, which gives (c), or else $\omega(x_n) < \omega(z)$, which we now assume. Choose an equilibrium $u_1 \in \omega(x_1)$. By Lemma 1.3 there exists an open set W containing $\omega(z)$ and $t_0 \geqslant 0$ such that $u_1 \leqslant \Phi_t(W)$ for all $t \geqslant t_0$. Arguing as in Case I, we obtain $u_1 \leqslant \Phi_t(x_m)$ for some m and all large t. Since $u_1 \in \omega(x_m)$, it follows that $\omega(x_m) = u_1$ by Corollary 1.9, and therefore $\omega(x_n) = \{u_1\}$ as asserted in case (b). Finally, if $u \in E$ and $u < \omega(z)$, we argue as above that $\omega(x_m) \geqslant u$ for some m, which implies $u_1 \geqslant u$.

To prove $z \in \overline{\operatorname{Int} Q}$, use SOP to obtain a neighborhood U_n of x_n such that $\Phi_t(x_{n-1}) \leqslant \Phi_t(U_n) \leqslant \Phi_t(x_{n+1})$ for all large t, implying $U_n \subset Q$. A similar argument proves the analogous assertion in (b). ☐

The following addendum to the Sequential Limit Set Trichotomy provides important stability information. In essence, it associates various kinds of stable points to arbitrary elements $z \in BC$:

PROPOSITION 2.4. *Assume X is normally ordered. In cases* (a), (b) *and* (c) *of the Sequential Limit Set Trichotomy, the following statements are valid respectively*:

(a) *z and u_0 are stable from below*;

(b) *z is not stable from below, $\omega(z)$ is unstable from below, and u_1 is asymptotically stable from above*;

(c) *z is asymptotically stable from below, and $z \in \overline{A}$.*

PROOF. (a) follows from Proposition 1.26(a) and (b).

(b) The first two assertions are trivial. To prove $u_1 \in A_+$, take $w = x_n$ for some large n in the last assertion of (b) and apply 1.25(d) with $a = u_1$.

(c) follows from 1.25(d), taking $b = z$. ☐

We expect in real world systems that observable motions are stable trajectories. Our next result implies stable trajectories approach equilibria.

PROPOSITION 2.5. $S \cap (BC \cup AC) \subset Q$.

PROOF. When $z \in S \cap (BC \cup AC)$, only (a) and (c) of the Sequential Limit Set Trichotomy are possible, owing to continuity at z of the function $x \mapsto \omega(x)$. In both cases $z \in Q$. ☐

The inclusion $S \subset Q$ suggests trajectories issuing from nonquasiconvergent points are unlikely to be observed; the next result implies that their limit sets are, not surprisingly, unstable. There are as many concepts of instability as there are of stability, but for our purposes the following very strong property suffices: A set $M \subset X$ is *unstable from above* provided there is an equilibrium $u > M$ such that $\omega(x) = \{u\}$ if $u > x > y$, $y \in M$. Such an equilibrium u is unique, and SOP implies it attracts all points $< u$ in some neighborhood of u. *Unstable from below* is defined dually.

THEOREM 2.6. *Assume $z \in BC \setminus Q$ (respectively, $z \in AC \setminus Q$). Then $\omega(z)$ is unstable from below (resp., above).*

PROOF. To fix ideas we assume $z \in BC \setminus Q$. Then there exists a sequence $x_n \to z$ and an equilibrium u_1 as in conclusion (b) of the Sequential Limit Set Trichotomy. Suppose $u_1 < x < y$, $y \in \omega(z)$. SOP implies there exist open sets W_x and W_y containing x and y, respectively, and $t_0 \geqslant 0$, such that $\Phi_t(W_x) \leqslant \Phi_t(W_y)$ for all $t \geqslant t_0$. As $\Phi_s(z) \in W_y$ for some large s, by continuity $\Phi_s(x_n) \in W_y$ for some large n. Thus $u_1 \leqslant \Phi_t(x) \leqslant \Phi_{t+s}(x_n)$ for all $t \geqslant t_0$. Letting $t \to \infty$ and using the fact that $\omega(x_n) = \{u_1\}$, we find that $\omega(x) = \{u_1\}$. □

A set is *minimal* if it is nonempty, closed and invariant, and no proper subset has these three properties. Every positively invariant nonempty compact set contains a minimal set (by Zorn's Lemma). A minimal set containing more than one point is called *nontrivial*.

COROLLARY 2.7. *A compact, nontrivial minimal set M that meets BC (respectively, AC) is unstable from below (resp., above).*

PROOF. Suppose $z \in M \cap BC$. The assumptions on M imply $M = \omega(z)$ and $M \cap E = \emptyset$. Therefore $z \in BC \setminus Q$, and instability follows from Theorem 2.6. □

When X is a convex subset of a vector space, an alternative formulation of Theorem 2.6 is that $\omega(z)$ belongs to the upper boundary of the basin of attraction of the equilibrium u_1. Corollary 2.7 implies that periodic orbits are unstable. Theorem 2.6 is motivated by Theorem 1.6 in Hirsch [79].

The following sharpening of Theorem 1.19, due to Smith and Thieme [199], is an immediate corollary of the Sequential Limit Set Trichotomy.

THEOREM 2.8. *If $J \subset X$ is a totally ordered arc having property* (C), *then $J \setminus Q$ is a discrete, relatively closed subset of J; hence it is countable, and finite when J is compact.*

PROOF. Every limit point z of $J \setminus Q$ is strongly accessible from above or below by a sequence $\{\tilde{x}_n\}$ in $J \setminus Q$. As Property (C) implies $J \subset BC \cup AC$, there is a sequence $\{x_n\}$ satisfying (a), (b) or (c) of Theorem 2.3 (or its dual result), all of which imply $x_n \in Q$. Thus $J \setminus Q$ contains none of its limit points, which implies the conclusion. □

The following result sharpens Theorems 1.30 and 2.8:

PROPOSITION 2.9. *Assume X is normally ordered and every point is accessible from above and below. Let $J \subset X$ be a totally ordered compact arc having property* (C), *with* *endpoints $a < b$ such that $\omega(a)$ is an equilibrium stable from below and $\omega(b)$ is an equilibrium stable from above. Then J contains a point whose trajectory converges to a stable equilibrium.*

PROOF. Denote by C_s (respectively: C_+, C_-) the set of convergent points whose omega limits belong to S (resp.: to S_+, S_-). Then $C_+ \cap C_- = C_s$ by Proposition 1.25(b).

Set $\sup(J \cap C_-) = z \in J$.

Case 1: $z \notin C_-$. Then $z > a$. Choose a sequence $x_1 < x_2 < \cdots < z$ in $J \cap C_-$ such that $x_n \to z$. By the Sequential Limit Set Trichotomy 2.3 it suffices to consider the following three cases:

(a) There exists $u_0 \in E$ such that

$$\omega(x_n) < \omega(x_{n+1}) < \omega(z) = \{u_0\}.$$

This is not possible, because $u_0 \in S_-$ by Proposition 2.4(a), yielding the contradiction $z \in C_-$.

(b) There exists $u_1 = \sup\{u \in E\colon\ u < \omega(z)\}$, and for all n we have

$$\omega(x_n) = \{u_1\} < \omega(z).$$

Now 2.4(b) has $u_1 \in S_+$, hence $x_n \in C_+$. Therefore $x_n \in C_+ \cap C_- = C_s$, as required.

(c) $\omega(x_n) = \omega(z)$. This is not possible because $x_n \in C_-$ and $\omega(z) = \omega(x_n)$ implies the contradiction $z \in C_-$.

Thus (b) holds, validating the conclusion when $z \notin C_-$.

Case 2: $z \in C_-$. If $z = b$ then $z \in C_+ \cap C_- = C_s$ and there is nothing more to prove. Henceforth we assume $z < b$.

The closed subinterval $K \subset J$ with endpoints z, b satisfies the hypotheses of the theorem. Set $\inf(K \cap C_+) = w \in K$. The dual of the reasoning above shows that if $w \notin C_+$ then the conclusion of the theorem is true.

From now on we assume $w \in C_+$. If $w = z$ there is nothing more to prove, so we also assume $w > z$. Let $L \subset K$ be the closed subinterval with endpoints w and z. Let $\{\bar{x}_n\}$ be a sequence in L converging to w from below.

One of the conclusions (a), (b) or (c) of 2.3 holds. Referring to the corresponding parts of 2.4, we see in case (a) that $\omega(w)$ is an equilibrium $\bar{u}_0$ that is stable from below; but $w > z$, so this contradicts the definition of z. If (b) holds, $\omega(\bar{x}_n)$ is an equilibrium $\bar{u}_1$ stable from above. But $\bar{x}_n < w$, so this contradicts the definition of w. In case (c) we have for all n that $\omega(\bar{x}_n) = \omega(w)$, which is an equilibrium stable from above. But $\bar{x}_n < w$ for $n > 1$, again contradicting the definition of w. □

In the following result the assumption on equilibria holds when Φ has a global compact attractor.

PROPOSITION 2.10. *Assume X is an open subset of a strongly ordered Banach space, Φ is strongly monotone, and every equilibrium has a neighborhood attracted to a compact set. Let $J \subset X$ be a totally ordered compact arc, with endpoints $a < b$ such that $\omega(a)$ is* *an equilibrium stable from below and* $\omega(b)$ *is an equilibrium stable from above. Then* J *contains a point whose trajectory converges to a stable equilibrium.*

PROOF. Apply Proposition 2.9 to the to the SOP semiflow $\widehat{\Phi}$ in the normally ordered space $\widehat{X}$ (see Section 1.7), to obtain an equilibrium p that is stable for $\widehat{\Phi}$. This means p is order stable for Φ, hence stable for Φ by Proposition 1.28. □

COROLLARY 2.11. *Let* X *be a p-convex open set in an ordered Banach space* Y. *Assume* Φ *has a compact global attractor. Suppose that either* Y *is normally ordered, or* Y *is strongly ordered and* Φ *is strongly monotone. Then*:

(i) *There is a stable equilibrium.*

(ii) *Let* $u, v \in X$ *be such that* $u < v$ *and there exist real numbers* $r, s > 0$ *such that* $u < \Phi_r(u)$, $\Phi_s(v) < v$. *Then there is a stable equilibrium in* $[u, v]$.

In case (ii) *with* Y *normally ordered, the hypothesis of a global attractor can be replaced the assumption that the line segment joining* u *to* v *from satisfies condition* (C).

PROOF. We first prove (ii). Monotonicity shows that $\omega(x) \subset [u, v]$ for all $x \in [u, v]$. The Convergence Criterion implies

$$\Phi_t(u) \to a \in E \cap [u, v], \qquad \Phi_t(v) \to b \in E \cap [u, v].$$

We claim that $a \in S_-$ and $b \in S_+$, and $a \in S$ is stable if $a = b$. When Y is normal this follows from Propositions 1.25(b) and (d), and it is easy to prove directly when Φ is strongly monotone. Suppose $a < b$. By p-convexity and Theorems 2.9 and 2.10, the line segment from a to b lies in $[u, v] \cap X$ and contains a point whose x such that $\omega(x)$ is a stable equilibrium z. As noted above, $z \in [u, v]$.

We prove (i) by finding u and v as in (ii). By Theorem 2.8 and compactness of the global attractor, there is a minimal equilibrium p and a maximal equilibrium $q > p$. As X is open, it contains a totally ordered line segment $J < p$. By Theorem 1.19 J contains a quasiconvergent point $u < p$. As $\omega(u) \leqslant p$, minimality of p implies $\Phi_t(u) \to p$. Similarly there exist $v > q$ with $\Phi_t(v) \to q$. It follows from SOP that $u < \Phi_r(u)$, $\Phi_s(v) < v$ for some $r, s > 0$. □

For strongly monotone semiflows, the existence of order stable equilibria in attractors was treated in Hirsch [68,69,73].

2.2. *Generic quasiconvergence and stability*

The following result adapted from Smith and Thieme [197] refines Theorems 1.22 and 1.21:

THEOREM 2.12. (i) $AC \cup BC \subset \overline{\operatorname{Int} Q} \cup C$. *Therefore if* $AC \cup BC$ *is dense, so is* Q.

(ii) $(\operatorname{Int} AC) \cup (\operatorname{Int} BC) \subset \overline{\operatorname{Int} Q}$. *Therefore if* $(\operatorname{Int} AC) \cup (\operatorname{Int} BC)$ *is dense, so is* $\operatorname{Int} Q$.

PROOF. Every $z \in BC$ is the limit of an omega compact sequence $x_1 < x_2 < \cdots$ such that (a), (b) or (c) of the Sequential Limit Set Trichotomy Theorem 2.3 holds, and $z \in \overline{\operatorname{Int} Q} \cup C$ in each case; the proof for AC is similar.

To prove (ii), assume $z \in \operatorname{Int} BC$. If (a) holds for every point of a neighborhood W of z, then $W \subset C$, whence $z \in \operatorname{Int} Q$. If there is no such W, every neighborhood of z contains a point for which (b) or (c) holds, hence $z \in \overline{\operatorname{Int} Q}$. Similarly for $z \in \operatorname{Int} AC$. □

The next result extends Theorems 8.10 and 9.6 of Hirsch [73] and Theorem 3.9 of Smith and Thieme [197]:

THEOREM 2.13. *Assume X is normally ordered and* $\operatorname{Int}(BC \cup AC)$ *is dense. Then* $A \cup \operatorname{Int} C$ *is dense.*

PROOF. We argue by contradiction. If $A \cup \operatorname{Int} C$ is not dense, there exists an open set U such that

$$U \cap \overline{A} = \emptyset = U \cap \overline{\operatorname{Int} C}.$$

Suppose $z \in U \cap BC$, and let $\{x_n\}$ be a sequence in U strongly approximating z from below. Conclusion (b) of the Sequential Limit Set Trichotomy 2.3 is not possible because $z \notin \overline{\operatorname{Int} C}$, and conclusion (c) is ruled out because $z \notin \overline{A}$ (see Proposition 2.4(c)). Therefore conclusion (a) holds, which makes z convergent; likewise when $z \in U \cap AC$. Thus we have $C \supset U \cap (BC \cup AC)$, so $\operatorname{Int} C \supset U \cap \operatorname{Int}(BC \cup AC)$. But the latter set is nonempty by the density hypothesis, yielding the contradiction $U \cap \operatorname{Int} C \neq \emptyset$. □

The following theorem concludes that generic trajectories are not only quasiconvergent, but also stable. Its full force will come into play in the next subsection, under assumptions entailing a dense open set of convergent points.

THEOREM 2.14. *If X is normally ordered and* $\operatorname{Int}(BC \cap AC)$ *is dense, then* $\operatorname{Int}(Q \cap S)$ *is dense.*

PROOF. $\operatorname{Int} Q$ is dense by Theorem 2.12. To prove density of $\operatorname{Int} S$, it suffices to prove that if $z \in \operatorname{Int}(BC \cap AC)$, then every open neighborhood U of z meets $\operatorname{Int} S$. We can assume $z \notin \overline{A}$ because $A \subset \operatorname{Int} S$. Let $\{x_n\}$ be an omega compact sequence strongly approximating z from below. Suppose (b) or (c) of the Sequential Limit Set Trichotomy 2.3 holds. Then $x_m \in U$ for $m \geqslant m_0$. Fix $m \geqslant m_0$. It follows from Proposition 1.25(d) (with $a = x_m$, $x = x_{m+1}$, $b = x_{m+2}$) that $x_{m+1} \in A$, hence $z \in \overline{A}$; this is proved similarly when $\{x_n\}$ strongly approximates z from above.

Henceforth we can assume z belongs to the open set $W = \operatorname{Int}(BC \cap AC) \setminus \overline{A}$, and consequently that there are omega compact sequences $\{x_n\}$, $\{y_n\}$ strongly approximating z from below and above respectively, for which Theorem 2.3(a) and its dual hold respectively. Then Proposition 1.26 implies $z \in S_+ \cap S_-$, whence $z \in S$ by Proposition 1.25(b). Thus the open set W is contained in $\operatorname{Int} S$, and we have proved $\operatorname{Int} S$ is dense. It follows that $\operatorname{Int} S \cap \operatorname{Int} Q$ is dense. □

2.3. *Improving the limit set dichotomy for smooth systems*

The aim now is to strengthen the Limit Set Dichotomy with additional hypotheses, especially smoothness, in order to obtain the following property:

(ILSD) A semiflow satisfies the *Improved Limit Set Dichotomy* if $x_1 < x_2$ implies that either
- (a) $\omega(x_1) < \omega(x_2)$, or
- (b) $\omega(x_1) = \omega(x_2) = e \in E$.

We begin with some definitions.

Let X be a subset of the Banach space Y. A map $f : X \to Y$ is said to be *locally C^1 at* $p \in X$ if there exists a neighborhood U of p in X and a continuous *quasiderivative* map $f' : U \to L(Y)$, where $L(Y)$ is the Banach space of bounded operators on Y, such that

$$f(x) - f(x_0) = f'(x_0)(x - x_0) + \phi(x, x_0)|x - x_0|, \quad x, x_0 \in U$$

with $\phi(x, x_0) \to 0$ as $x \to x_0$. The following result gives a setting where the quasiderivative is uniquely determined by f. We denote the open ball in Y of center p and radius r by $B_Y(p, r) := \{y \in Y\colon |y - p| < r\}$.

LEMMA 2.15. *Let $p \in X \subset Y$ where Y is a strongly ordered Banach space. Assume $f : X \to Y$ is locally C^1 at p, and suppose that either $B_Y(p, r) \cap Y_+ \subset X$ or $B_Y(p, r) \cap (-Y_+) \subset X$ for some $r > 0$. Then $f'(p)$ is uniquely defined.*

PROOF. Suppose $B_Y(p, r) \cap Y_+ \subset X$, the other case being similar. Fix $w \gg 0$ and let $y \in Y$. As $w + y/n := k_n \geqslant 0$ for large n, $y = n(k_n - w)$ so $Y = Y_+ - Y_+$.

Assume

$$f(x) - f(p) = A(x - p) + \phi(x, p)|x - p| = B(x - p) + \psi(x, p)|x - p|,$$

where $A, B \in L(Y)$ and $\phi, \psi \to 0$ as $x \to p$ in X. It suffices to show that $Av = Bv$ for all $v \geqslant 0$. The segment $x = p + sv \in X$ for all small $s \geqslant 0$. Inserting it in the formula above, dividing by s, and letting $s \to 0$ yields the desired result. □

Let Φ be a monotone semiflow on the subset X of the strongly ordered Banach space Y. Concerning X and the set of equilibria E, we assume the following condition on the pair (Y, X):

(OC) Either X is an order convex subset of Y or $E \subset \operatorname{Int} X$. For each $e \in E$ there exists $r > 0$ such that either $B_Y(e, r) \cap Y_+ \subset X$ or $B_Y(e, r) \cap (-Y_+) \subset X$.

This relatively minor restriction is automatically satisfied if X is an open set, an order interval, or the cone Y_+. The second assertion of (OC) trivially holds if $E \subset \operatorname{Int} X$.

We will also assume the following two conditions hold for some $\tau > 0$. A compact, strongly positive linear operator is called a *Krein–Rutman* operator.

(M) $x_1 < x_2 \Longrightarrow \Phi_\tau(x_1) \ll \Phi_\tau(x_2)$
(D*) Φ_τ is locally C^1 at each $e \in E$, with $\Phi'_\tau(e)$ a Krein–Rutman operator.

As motivation for (D*), consider the case that X is an open set in Y and Φ_τ is C^1. If $x \in X$, $y \in Y_+$, $h > 0$, and $x + hy \in X$, then $(\Phi_\tau(x+hy) - \Phi_\tau(x))/h \geqslant 0$ by monotonicity; on taking the limit as $h \to 0$, we get $\Phi'_\tau(x)y \geqslant 0$. Consequently, $\Phi'_\tau(x)Y_+ \subset Y_+$, and hence the assumption that $\Phi'_\tau(x)$ is strongly positive is not such a severe one. Typically, one usually must verify it anyway to prove that Φ_τ is strongly monotone.

Observe that (M) implies that Φ is strongly order preserving on X.

THEOREM 2.16 (Improved Limit Set Dichotomy). *Let Φ be a monotone semiflow on a subset X of the strongly ordered Banach space Y for which* (OC), (M), *and* (D*) *are satisfied. Then* (ILSD) *holds.*

In particular, (ILSD) holds if X is open, the semiflow Φ continuously differentiable and strongly monotone, and the derivative $\Phi'_t(e)$ is a Krein–Rutman operator at each $e \in E$.

Before giving the proof, we explore the spectral and dynamical implications of (D*).

2.3.1. *The Krein–Rutman theorem* The spectrum of a linear operator $A : Y \to Y$ is denoted by $\mathrm{Spec}(A)$. When A is compact (i.e., completely continuous), $\mathrm{Spec}(A)$ consists of a countable set of eigenvalues and perhaps 0, and the eigenvalues have no accumulation point except possibly 0.

Let $\rho(A)$ be the *spectral radius* of A, that is, $\rho(A) = \max\{|\lambda|: \lambda \in \mathrm{Spec}(A)\}$. Denote the null space of A by $N(A)$ and the range by $\mathrm{Im}(A)$.

The set $\mathrm{KR}(Y)$ of Krein–Rutman operators on Y is given the metric induced by the uniform norm.

THEOREM 2.17 (Krein–Rutman). *Let $A \in \mathrm{KR}(Y)$ and set $r = \rho(A)$. Then Y decomposes into a direct sum of two closed invariant subspaces Y_1 and Y_2 such that $Y_1 = N(A - rI)$ is spanned by $z \gg 0$ and $Y_2 \cap Y_+ = \{0\}$. Moreover, the spectrum of $A|Y_2$ is contained in the closed ball of radius $\nu < r$ in the complex plane.*

See Krein and Rutman [104], Takáč [214] or Zeidler [244] for proofs.

It follows that each $A \in \mathrm{KR}(Y)$ has a unique unit eigenvector $z(A) \in Y_+$, and $z(A) \in \mathrm{Int}\, Y_+$, $Az(A) = \rho(A)z(A)$.

LEMMA 2.18. *$\rho(A)$ and $z(A)$ are continuous functions of $A \in \mathrm{KR}(Y)$.*

PROOF. The upper semicontinuity of the spectral radius follows from the upper semicontinuity of the spectrum as a function of the operator (Kato [92]). The lower semicontinuity follows from the lower semicontinuity of isolated parts of the spectrum (Kato [92, Chapter IV, Theorem 3.1, Remark 3.3, Theorem 3.16]). Let P_A be the projection onto $N(A) - \rho(A)I)$ along $\operatorname{Im}(A - \rho(A)I)$. Continuity of $A \mapsto P_A$ is proved in [92, Chapter IV, Theorem 3.16]. Let $A_n \to A$ in $\mathrm{KR}(Y)$ and set $z_n = z(A_n)$, $z = z(A)$. Then $(I - P_A))z_n = (P_{A_n} - P_A)z_n \to 0$ as $n \to \infty$, and $\{P_A z_n\}$ is precompact, so $\{z_n\}$ is precompact. If $z_{n_i} \to u$ for some subsequence, then

$$P_A u = \lim A_{n_i} z_{n_i} = \lim \rho(A_{n_i}) z_{n_i} = \rho(A)u.$$

Uniqueness of the positive eigenvector for A (Theorem 2.17) implies $u = z$ and $z_n \to z$. □

For technical reasons it is useful to employ a norm that is more compatible with the partial order. If $w \in \operatorname{Int} Y_+$ is fixed, then the set $U = \{y \in Y\colon -w \ll y \ll w\}$ is an open neighborhood of the origin. Consequently, if $y \in Y$, then there exists $t_0 > 0$ such that $t_0^{-1} y \in U$, hence, $-t_0 w \ll y \ll t_0 w$. Define the w-norm by

$$\|y\|_w = \inf\{t > 0\colon -tw \leqslant y \leqslant tw\}.$$

Since $w \in \operatorname{Int} Y_+$, there exists $\delta > 0$ such that for all $y \in Y \setminus \{0\}$ we have $w \pm \delta \frac{y}{|y|} \in Y_+$. Thus

$$\|y\|_w \leqslant \delta^{-1} |y|$$

holds for all $y \in Y$, implying that the w-norm is weaker than the original norm. In fact, the two norms are equivalent if Y_+ is normal, but we will have no need for this result. See Amann [6] and Hirsch [73] for more results in this direction. It will be useful to renormalize the positive eigenvector $z(A)$ for $A \in \mathrm{KR}(Y)$. The next result says this can be done continuously. Continuity always refers to the original norm topology on Y unless the contrary is explicitly stated.

LEMMA 2.19. *Let* $Z(A) = z(A)/\|z(A)\|_w$ *and* $\beta(A) = \sup\{\beta > 0\colon Z(A) \geqslant \beta w\}$. *Then* $\beta(A) > 0$, $Z(A) \geqslant \beta(A)w$, *and the maps* $A \to Z(A)$ *and* $A \to \beta(A)$ *are continuous on* $\mathrm{KR}(Y)$.

PROOF. Since the w-norm is weaker than the original norm, the map $A \mapsto \|z(A)\|_w$ is continuous. This implies that $Z(A)$ is continuous in A. It is easy to see that $\beta(A) > 0$. Let $\epsilon > 0$ satisfy $2\epsilon < \beta(A)$ and let $A_n \to A$ in $\mathrm{KR}(Y)$. Then $-\epsilon w \leqslant Z(A) - Z(A_n) \leqslant \epsilon w$ for all large n by continuity of Z and because the w-norm is weaker than the original norm. Therefore, $Z(A_n) = Z(A_n) - Z(A) + Z(A) \geqslant (\beta(A) - \epsilon)w$, so $\beta(A_n) \geqslant \beta(A) - \epsilon$ for all large n. Similarly, $Z(A) = Z(A) - Z(A_n) + Z(A_n) \geqslant (\beta(A_n) - \epsilon)w$ for all large n, so $\beta(A) \geqslant \beta(A_n) - \epsilon$ for all large n. Thus, $\beta(A) - \epsilon \leqslant \beta(A_n) \leqslant \beta(A) + \epsilon$ holds for all large n, completing the proof. □

The key to improving the Limit Set Dichotomy is to show that the omega limit set of a point x that is quasiconvergent but not convergent, is uniformly unstable in the linear approximation. The direction of greatest instability at $e \in \omega(x)$ is the positive direction $z(e) := z(\Phi'_\tau(e))$. The number $\rho(e) := \rho(\Phi'_\tau(e))$ gives a measure of the instability.

Nonordering of Limit Sets means that positive directions are, in some rough sense, "transverse" to the limit set. Thus our next result means that the limit set is uniformly unstable in a transverse direction.

LEMMA 2.20. *Assume* (D*). *Let x be quasiconvergent but not convergent. Then $\rho(e) > 1$ for all $e \in \omega(x)$.*

PROOF. Fix $e \in \omega(x)$. Since $\omega(x)$ is connected, e is the limit of a sequence $\{e_n\}$ in $\omega(x) \cap U \setminus \{e_0\}$, where U is the neighborhood of e in the definition of Φ_τ is locally C^1 at e. Then

$$e_0 - e_n = \Phi_\tau(e) - \Phi_\tau(e_n) = \Phi'_\tau(e)(e - e_n) + \mathrm{o}\big(|e - e_n|\big),$$

where $\mathrm{o}(|e - e_n|)/|e - e_n| \to 0$ as $n \to \infty$. Put $v_n = (e - e_n)/|e - e_n|$. Then

$$v_n = \Phi'_\tau(e)v_n + r_n, \quad r_n \to 0, \quad n \to \infty.$$

The compactness of $\Phi'_\tau(e)$ implies that v_n has a convergent subsequence v_{n_i}; passing to the limit along this subsequence leads to $v = \Phi'_\tau(e)v$ for some unit vector v. Thus $\rho(e) \geqslant 1$. If $\rho(e) = 1$, then the Krein–Rutman Theorem implies $v = rz(e)$ where $r = \pm 1$. Consequently,

$$(e - e_{n_i})/|e - e_{n_i}| \to rz(e)$$

as $i \to \infty$. It follows that $e \ll e_{n_i}$ or $e \gg e_{n_i}$ for all large i, contradicting the Nonordering of Limit Sets. □

PROOF OF THEOREM 2.16. By the Limit Set Dichotomy (Theorem 1.16), it suffices to prove: If $x_1 < x_2$ and $\omega(x_1) = \omega(x_2) = K \subset E$, then K is a singleton. K is compact and connected, unordered by the Nonordering of Limit Sets, and consists of fixed points of Φ_τ. Arguing by contradiction, we assume K is not a singleton.

Set $v_n = \Phi_{n\tau}(x_1)$, $u_n = \Phi_{n\tau}(x_2)$. Then $\mathrm{dist}(K, u_n) \to 0$ and $\mathrm{dist}(K, v_n) \to 0$ as $n \to \infty$. Moreover (M) and the final assertion of the Limit Set Dichotomy imply

$$u_n - v_n \gg 0, \qquad u_n - v_n \to 0.$$

Fix $w \gg 0$ and define real numbers

$$\alpha_n = \sup\{\alpha \in \mathbb{R}\colon \alpha \geqslant 0,\ \alpha w \leqslant u_n - v_n\}.$$

Then $\alpha_n > 0$ and $\alpha_n \to 0$.

To simplify notation, define $S : X \to X$ by $S(x) := \Phi_\tau(x)$. Choose $e_n \in K$ such that $v_n - e_n \to 0$ as $n \to \infty$. By Lemma 2.20, local smoothness of Φ_τ and compactness of K, there exists $r > 1$ such that $\rho(e) > r$ for all $e \in K$. Let $z_n = Z(e_n)$ be the normalized positive eigenvector for $S'(e_n) = \Phi'_\tau(e_n)$ so $\|z_n\|_w = 1$ and $z_n \leqslant w$. By Lemma 2.19, there exists $\epsilon > 0$ such that $\beta(e_n) \geqslant \epsilon$ for all n. In particular, $w \geqslant z_n \geqslant \epsilon w$ for all n.

Fix a positive integer l such that $r^l\epsilon > 1$.

For each $e \in K$, by (D*) we can choose an open neighborhood W_e of e in X and a continuous map $S' : W_e \to L(Y)$ such that for $x, x_0 \in W_e$ we have

$$Sx - Sx_0 = S'(x_0)(x - x_0) + \phi(x, x_0)|x - x_0|, \qquad \lim_{x \to x_0} \phi(x, x_0) = 0.$$

Putting $x_0 = e$ and estimating norms, one easily sees that there exists a convex open neighborhood $U_e \subset W_e$ of e such that $S^i(U_e) \subset W_e$ for $1 \leqslant i \leqslant l$. Furthermore, a simple induction argument implies that S^l is locally C^1 at e with quasiderivative

$$\bigl(S^l\bigr)' : U_e \to L(Y), \qquad \bigl(S^l\bigr)'(x) = S'\bigl(S^{l-1}x\bigr) \circ S'\bigl(S^{l-2}x\bigr) \circ \cdots \circ S'(x).$$

By compactness of K there is a finite subset $\{e_1, \dots, e_\nu\} \subset K$ such that the sets U_{e_j} cover K. Set $U_j = U_{e_j}$, $W_j = W_{e_j}$. Then

$$K \subset \bigcup_{j=1}^{\nu} U_j, \qquad S^i(U_j) \subset W_j \quad (1 \leqslant i \leqslant l),$$

and for $z, z_0 \in U_j$

$$S^l(z) - S^l(z_0) = \bigl(S^l\bigr)'(z_0)(z - z_0) + \phi_{l,j}(z, z_0)|z - z_0|, \qquad \lim_{z \to z_0} \phi_{l,j}(z, z_0) = 0,$$

and the usual chain rule expresses $(S^l)'$ in terms of S'.

By (OC), either X is order convex in Y or $E \subset \operatorname{Int} X$. In the order convex case, from $v_n \ll v_n + \alpha_n w \leqslant u_n$ we infer that $v_n + s\alpha_n w \in X$ for all $s \in [0, 1]$. Since $v_n - e_n \to 0$, $v_n - u_n \to 0$, and $\alpha_n \to 0$, for sufficiently large n there exists $j(n) \in \{1, \dots, \nu\}$ such that $U_{j(n)}$ contains the points v_n, u_n, e_n, and $v_n + s\alpha_n w$ for all $s \in [0, 1]$. When $E \subset \operatorname{Int} X$ the same conclusion holds, and we can take U_j, V_j to be open in Y.

Lemma 2.15 justifies the application of the fundamental theorem of calculus to the map $[0, 1] \to X$, $s \mapsto S^l(v_n + s\alpha_n w)$, leading to

$$S^l(v_n + \alpha_n w) - S^l(v_n) = \bigl(S^l\bigr)'(e_n)(\alpha_n w) + \alpha_n \delta_n$$

and

$$\delta_n = \int_0^1 \bigl[\bigl(S^l\bigr)'(v_n + \eta\alpha_n w) - \bigl(S^l\bigr)'(e_n)\bigr] w \, \mathrm{d}\eta.$$

Using that $v_n + \alpha_n w - e_n \to 0$, K is compact, and $(S^l)'$ is continuous, it is easy to show that

$$\lim_{n \to \infty} \max_{0 \leqslant \eta \leqslant 1} \bigl|\bigl[\bigl(S^l\bigr)'(v_n + \eta\alpha_n w) - \bigl(S^l\bigr)'(e_n)\bigr] w\bigr| = 0.$$

It follows that $d_n := \|\delta_n\|_w \to 0$ as $n \to \infty$. Because $w \geqslant z_n \geqslant \epsilon w \gg 0$ and $\delta_n \geqslant -d_n w$, for sufficiently large n we have:

$$\begin{aligned} S^l(v_n + \alpha_n w) - S^l(v_n) &\geqslant \big[(S^l)'(e_n)\big]\alpha_n w - \alpha_n d_n w \\ &\geqslant \big[S'(e_n)\big]^l \alpha_n w - \alpha_n d_n w \\ &\geqslant r^l \alpha_n z_n - \alpha_n d_n w \\ &\geqslant (r^l\epsilon - d_n)\alpha_n w \\ &\geqslant \alpha_n w, \end{aligned}$$

and therefore

$$u_{n+l} = S^l(u_n) \geqslant S^l(v_n + \alpha_n w) \geqslant S^l v_n + \alpha_n w = v_{n+l} + \alpha_n w.$$

Thus $\alpha_n w \leqslant u_{n+l} - v_{n+l}$, so the definition of α_{n+l} implies $\alpha_{n+l} \geqslant \alpha_n > 0$ for all sufficiently large n. Therefore the sequence $\{\alpha_i\}_{i\in\mathbb{N}_+}$, which converges to 0, contains a nondecreasing positive subsequence $\{\alpha_{n+kl}\}_{k\in\mathbb{N}_+}$. This contradiction implies K is a singleton. □

A drawback of the Improved Limit Set Dichotomy, Theorem 2.16, is that the topology on X comes from a strongly ordered Banach space $Y \supset X$, severely limiting its application to infinite-dimensional systems. The following extension permits use of (ILSD) in more general spaces:

PROPOSITION 2.21. *Let X^1, X^0 be ordered spaces such that $X^1 \subset X^0$ and the inclusion map $j : X^1 \hookrightarrow X^0$ is continuous and order preserving. For $k = 0, 1$ let Φ^k be a monotone semiflow on X^k with compact orbit closures. Assume for all $t > 0$ that Φ^0_t maps X^0 continuously into X^1, and $\Phi^0_t|X^1 = \Phi^1_t$. If* (ILSD) *holds for Φ^1, it also holds for Φ^0.*

PROOF. Denote the closure in X^k of any $S \subset X^k$ by $\mathsf{C}_k S$. For $k \in \{0, 1\}$ and $x \in X^k$, let $O_k(x)$ and $\omega_k(x)$ respectively denote the orbit and omega limit set of x.

The hypotheses imply that the compact set $\mathsf{C}_0 O_0(x)$, which is positively invariant for Φ^0, is mapped homeomorphically by Φ^0_1 onto $\mathsf{C}_1 O_1(y) \subset X^1$, which is positively invariant for Φ^1. As Φ^0 and Φ^1 coincide in X^1, we see that $\omega_0(x) = \omega_1(y)$ as compact sets. Hence Φ^0 and Φ^1 have the same collection of omega limit sets, which implies the conclusion. □

THEOREM 2.22 (Improved Sequential Limit Set Trichotomy). *Assume* (ILSD). *Let $\{\tilde{x}_n\}$ be a sequence approximating $z \in BC$ from below, with $\overline{\bigcup_n \omega(\tilde{x}_n)}$ compact. Then there is a subsequence $\{x_n\}$ such that exactly one of the following three conditions holds for all n:*

(a) *There exists $u_0 \in E$ such that*

$$\omega(x_n) < \omega(x_{n+1}) < \omega(z) = \{u_0\}$$

and

$$\lim_{n\to\infty} \operatorname{dist}\big(\omega(x_n), u_0\big) = 0.$$

(b) *There exists* $u_1 = \sup\{u \in E\colon\ u < \omega(z)\}$, *and*

$$\omega(x_n) = \{u_1\} < \omega(z).$$

In this case $z \in \overline{\operatorname{Int} C}$. *Moreover* z *has a neighborhood* W *such that if* $w \in W$, $w < z$ *then* $\Phi_t(w) \to u_1$ *and* $\Phi_t(w) > u_1$ *for sufficiently large* t.

(c′) *There exists* $u_2 \in E$ *such that* $\omega(x_n) = \omega(x_0) = u_2$.

Note that z is convergent in (a), strongly accessible from below by convergent points in (b), and convergent in (c′).

PROOF. Conclusions (a) and (b) are the same as in the Sequential Limit Set Trichotomy, Theorem 2.3. If 2.3(c) holds, then (c′) follows from (ILSD). □

PROPOSITION 2.23. *Assume* (ILSD). *If* $x \in BC \setminus C$ *then* $\omega(x)$ *is unstable from below. If* $x \in AC \setminus C$ *then* $\omega(x)$ *is unstable from above.*

PROOF. This is just Theorem 2.6 if $x \notin Q$. If $x \in BC \cap (Q \setminus C)$, we must have conclusion (b) of Theorem 2.22. This provides $u_1 \in E$ such that $\omega(x_n) = \{u_1\}$ for all n, and the remainder of the proof mimics that of Theorem 2.6. □

A consequence of Proposition 2.23 is that if $x \in BC \cap AC$ is nonconvergent, then $\omega(x)$ lies in both the upper boundary of the basin of attraction of an equilibrium u_0 and the lower boundary of the basin of attraction of an equilibrium v_0, where $u_0 < L < v_0$. Thus $\omega(x)$ forms part of a separatrix separating the basins of attraction of u_0 and v_0.

2.4. *Generic convergence and stability*

The following result concludes that the set C of convergent points is dense and open in totally ordered arcs:

THEOREM 2.24. *Assume* (ILSD) *and let* $J \subset X$ *be a totally ordered arc having property* (C). *Then* $J \setminus C$ *is a discrete, relatively closed subset of* J; *hence it is countable, and finite when* J *is compact.*

PROOF. The proof is like that of Theorem 2.8, using the Improved Limit Set Trichotomy 2.22 instead of the Sequential Limit Set Trichotomy 2.3. □

We can now prove the following generic convergence and stability results:

THEOREM 2.25. *Assume* (ILSD).

(a) $AC \cup BC \subset \overline{\operatorname{Int} C} \cup C$. *In particular, if* $AC \cup BC$ *is dense, so is* $\operatorname{Int} C$ *is dense.*

(b) *If* $\operatorname{Int}(BC \cap AC)$ *is dense and* X *is normally ordered, then* $\operatorname{Int}(C \cap S)$ *is dense.*

PROOF. The proof of (a) is similar to that of Theorem 2.12: take $p \in X \setminus \operatorname{Int} C$ and use the Improved Limit Set Trichotomy (Theorem 2.22), instead of the Limit Set Trichotomy, to show that $p \in \overline{\operatorname{Int} C} \cup C$. Conclusion (b) follows from (a) and Theorem 2.14. □

THEOREM 2.26. *Assume X is a subset of a strongly ordered Banach space Y, and a dense open subset of X is covered by totally ordered line segments. Let* (M) *and* (D*) *hold. Then*:

(a) *The set of convergent points has dense interior.*

(b) *Suppose Y is normally ordered. Then the set of stable points has dense interior.*

(c) *Assume Y is normally ordered*; *X is open or order convex or a subcone of Y_+*; *and every closed totally ordered subset of E is compact. Then there is a stable equilibrium, and an asymptotically stable equilibrium when E is finite.*

PROOF. The assumption in (a) implies $BC \cap AC$ has dense interior and condition (OC) holds. Therefore the Improved Limit Set Dichotomy (ILSD) holds by Theorem 2.16, so (a) and (b) follow from Theorem 2.25(a). Conclusion (c) is a consequence of (a) and Theorem 1.30. □

As most orbits with compact closure converge to an equilibrium, it is natural to investigate the nature of the convergence. It might be expected that most trajectories converging to a stable equilibrium are eventually increasing or decreasing. We quote a theorem of Mierczyński that demonstrates this under quite general conditions for smooth strongly monotone dynamical systems, including cases when the equilibrium is not asymptotically stable in the linear approximation. Mierczyński assumes the following hypothesis:

(M_1) X is an open set in a strongly ordered Banach space Y. Φ is C^1 on $(0,\infty) \times X$ and strongly monotone, $\Phi_t'(x)$ is strongly positive for all $t > 0, x \in X$, and $\Phi_1'(x)$ is compact.

The following local trichotomy due to Mierczyński [138] builds on earlier work of Poláčik [161]:

THEOREM 2.27. *Assume* (M_1). *Then each equilibrium e satisfying $\rho(\Phi_1'(e)) \leqslant 1$ belongs to a locally invariant submanifold Σ_e of codimension one that is smooth and unordered and has the following property. If $\lim_{t\to\infty} \Phi_t(x) = e$, there exists $t_0 \geqslant 0$ such that one of the following holds as $t \to \infty$, $t \geqslant t_0$*:

(i) *$\Phi_t(x)$ decreases monotonically to e*;

(ii) *$\Phi_t(x)$ increases monotonically to e*;

(iii) *$\Phi_t(x) \in \Sigma_e$.*

Mierczyński also provides further important information: The trajectories in cases (i) and (ii) lie in curves tangent at e to the one-dimensional principle eigenspace Y_1 of $\Phi_1'(e)$ described in the Krein–Rutman Theorem 2.17. The hypersurface Σ_e is locally unique in a neighborhood of e. Its tangent space is the closed complementary subspace Y_2, hence Σ_e is transverse to $z = z(\Phi_1'(e)) \gg 0$ at e. Strong monotonicity implies that when (i) or (ii) holds, e is asymptotically stable for the induced local flow in Σ_e, even when e is not stable.

2.4.1. *Background and related results* Smith and Thieme [197,199] introduced the compactness hypothesis (C) and obtained the Sequential Limit Set Trichotomy. This tool streamlines many of the arguments and leads to stronger conclusions so the presentation here follows [197,199]. Takáč [210] extends the compactness hypothesis, which leads to additional stability concepts.

The results of Smith and Thieme [199] on generic convergence for SOP semiflows were motivated by earlier work of Poláčik [160], who obtained such results for abstract semilinear parabolic evolution systems assuming less compactness but more smoothness than Smith and Thieme.

The set A of asymptotically stable points can be shown to be dense under suitable hypotheses. See, e.g., Hirsch [73, Theorem 9.6]; Smith and Thieme [197, Theorems 3.13 and 4.1].

Hirsch [69] shows that if K is a nonempty compact, invariant set that attracts all points in some neighborhood of itself, then K contains an order-stable equilibrium.

It is not necessary to assume, as we have done here, that the semiflow is globally defined, that is, that trajectories are defined for all $t \geqslant 0$; many of the results adapt to local semiflows. See Hirsch [73], Smith and Thieme [199].

3. Ordinary differential equations

Throughout this section $\mathbb{R}^n$ is ordered by a cone K with nonempty interior. Our first objective is to explore conditions on a vector field that make the corresponding local semiflow monotone with respect to the order defined by K. It is convenient to work with time-dependent vector fields. We then investigate the long-term dynamics of autonomous vector fields f that are K-cooperative, meaning that K is invariant under the forward flow of the linearized system. These results are applied to competitive vector fields by the trick of time-reversal. In fairly general circumstances, limit sets of cooperative or competitive systems in $\mathbb{R}^n$ are invariant sets for systems in $\mathbb{R}^{n-1}$. This leads to particularly sharp theorems for $n = 2$ and 3.

A cone is *polyhedral* if it is the intersection of a finite family of closed half spaces. For example, the standard cone $\mathbb{R}^n_+$ is polyhedral, while the ice-cream cone is not.

The *dual cone* to K is the closed cone K^* in the dual space $(\mathbb{R}^n)^*$ of linear functions on $\mathbb{R}^n$, defined by

$$K^* = \left\{\lambda \in \left(\mathbb{R}^n\right)^*\colon\ \lambda(K) \geqslant 0\right\}.$$

To $\lambda \in K^*$ we associate the vector $a \in \mathbb{R}^n$ such that $\lambda(x) = \langle a, x\rangle$ where $\langle a, x\rangle$ denotes the standard inner product on $\mathbb{R}^n$. Under this association K^* is canonically identified with a cone in $\mathbb{R}^n$, namely, the set of vectors a such that a is normal to a supporting hyperplane H of K, and a and K lie in a common halfspace bounded by H.

We use the following simple consequence of general results on the separation of two closed convex sets:

$$x \in K \quad \Longleftrightarrow \quad \lambda(x) \geqslant 0 \quad (\lambda \in K^*).$$

See, e.g., Theorem 1.2.8 of Berman et al. [18].

PROPOSITION 3.1. *If $x \in K$, then $x \in \operatorname{Int} K$ if and only if $\lambda(x) > 0$ for all $\lambda \in K^* \setminus \{0\}$.*

PROOF. Suppose $x \in \operatorname{Int} K$, $\lambda \in K^* \setminus \{0\}$, and $v \in X$ satisfies $\lambda(v) \neq 0$. Then $x \pm \epsilon v \in K$ for sufficiently small $\epsilon > 0$, so

$$\lambda(x \pm \epsilon v) = \lambda(x) \pm \epsilon \lambda(v) \geqslant 0,$$

implying that $\lambda(x) > 0$.

To prove the converse, assume $\mu(x) > 0$ for all functionals μ in the compact set $\Gamma = \{\lambda \in K^*\colon \|\lambda\| = 1\}$. As $\inf\{\mu(x)\colon \mu \in \Gamma\} > 0$, continuity of the map $(x, \lambda) \mapsto \lambda(x)$ implies $\mu(y) > 0$ for all y in some neighborhood U of x and all $\mu \in \Gamma$. If $\lambda \in K^*$ then $\|\lambda\|^{-1}\lambda \in \Gamma$ and therefore $\lambda(y) > 0$ for all $y \in U$. This proves $U \subset K$. □

An immediate consequence of Proposition 3.1 is that if $x \in \partial K$, then there exists a nontrivial $\lambda \in K^*$ such that $\lambda(x) = 0$.

3.1. *The quasimonotone condition*

Let $J \subset \mathbb{R}$ be a nontrivial open interval, $D \subset \mathbb{R}^n$ an open set and $f : J \times D \to \mathbb{R}^n$ a locally Lipschitz function. We consider the ordinary differential equation

$$x' = f(t, x). \tag{3.1}$$

For every $(t_0, x_0) \in J \times D$, the initial value problem $x(t_0) = x_0$ has a unique noncontinuable solution defined on an open interval $J(t_0, x_0) \subset \mathbb{R}$. We denote this solution by $t \mapsto x(t, t_0, x_0)$. The notation $x(t, t_0, x_0)$ will carry the tacit assumption that $(t_0, x_0) \in J \times D$ and $t \in J(t_0, x_0)$. For fixed s_0, t_0 the map $x_0 \mapsto x(s_0, t_0, x_0)$ is a homeomorphism between open subsets of $\mathbb{R}^n$, the inverse being $x_0 \mapsto x(t_0, s_0, x_0)$.

System (3.1) is called *monotone* if $x_0 \leqslant x_1 \Longrightarrow x(t, t_0, x_0) \leqslant x(t, t_0, x_1)$.

The time-dependent vector field $f : J \times D \to \mathbb{R}^n$ satisfies the *quasimonotone condition* in D if for all $(t, x), (t, y) \in J \times D$ and $\phi \in K^*$ we have:

(QM) $x \leqslant y$ and $\phi(x) = \phi(y)$ implies $\phi(f(t, x)) \leqslant \phi(f(t, y))$.

The quasimonotone condition was introduced by Schneider and Vidyasagar [177] for finite-dimensional, autonomous linear systems and used later by Volkmann [224] for nonlinear infinite-dimensional systems. The following result is inspired by a result of Volkmann [224] and work of W. Walter [227]. See also Uhl [221], Walcher [226].

THEOREM 3.2. *Assume f satisfies* (QM) *in D, $t_0 \in J$, and $x_0, x_1 \in D$. Let $\prec$ denote any one of the relations $\leqslant, <, \ll$. If $x_0 \prec x_1$ then $x(t, t_0, x_0) \prec x(t, t_0, x_1)$, hence* (3.1) *is monotone. Conversely, if* (3.1) *is monotone then f satisfies* (QM).

PROOF. Assume that $x(t, t_0, x_i)$, $i = 0, 1$ are defined for $t \in [t_0, t_1]$ and $x_0 \leqslant x_1$. Let $v \gg 0$ be fixed and define $x_\epsilon := x_1 + \epsilon v$ and $f_\epsilon(t, x) := f(t, x) + \epsilon v$ for $\epsilon > 0$. Denote by $x(t) := x(t, t_0, x_0)$ and let $y_\epsilon(t) := x(t, t_0, x_\epsilon, \epsilon)$ denote the solution of the initial value problem $x'(t) = f_\epsilon(t, x)$, $x(t_0) = x_\epsilon$. It is well known that $y_\epsilon(t)$ is defined on $[t_0, t_1]$ for all sufficiently small ϵ. We show that $x(t) \ll y_\epsilon(t)$ for $t_0 \leqslant t \leqslant t_1$ and all sufficiently small $\epsilon > 0$. If not, then as $x(t_0) \ll y_\epsilon(t_0)$, there would exist $\epsilon > 0$ and $s \in (t_0, t_1]$ such that $x(t) \ll y_\epsilon(t)$ for $t_0 \leqslant t < s$ and $y_\epsilon(s) - x(s) \in \partial K$. By Proposition 3.1, there exists a nontrivial $\phi \in K^*$ such that $\phi(y_\epsilon(s) - x(s)) = 0$ but $\phi(y_\epsilon(t) - x(t)) > 0$ for $t_0 \leqslant t < s$. It follows that

$$\frac{\mathrm{d}}{\mathrm{d}t}\bigl[\phi\bigl(y_\epsilon(t)\bigr) - \phi\bigl(x(t)\bigr)\bigr]\bigg|_{t=s} \leqslant 0,$$

hence

$$\phi\bigl(f\bigl(s, y_\epsilon(s)\bigr)\bigr) < \phi\bigl(f\bigl(s, y_\epsilon(s)\bigr)\bigr) + \epsilon\phi(v) = \phi\bigl(f_\epsilon\bigl(s, y_\epsilon(s)\bigr)\bigr) \leqslant \phi\bigl(f\bigl(s, x(s)\bigr)\bigr),$$

where the last inequality follows from the one above. On the other hand, by (QM) we have

$$\phi\bigl(f\bigl(s, y_\epsilon(s)\bigr)\bigr) \geqslant \phi\bigl(f\bigl(s, x(s)\bigr)\bigr).$$

This contradiction proves that $x(t) \ll y_\epsilon(t)$ for $t_0 \leqslant t \leqslant t_1$ and all small $\epsilon > 0$. Since $y_\epsilon(t) = x(t, t_0, x_\epsilon, \epsilon) \to x(t, t_0, x_1)$ as $\epsilon \to 0$, by taking the limit we conclude that $x(t, t_0, x_0) \leqslant x(t, t_0, x_1)$ for $t_0 \leqslant t \leqslant t_1$.

Fix t_0 and $t \in J(t_0, x_0)$. As the map $h : x_0 \mapsto x(t, t_0, x_0)$ is injective, from $x_0 < x_1$ we infer $x(t, t_0, x_0) < x(t, t_0, x_1)$. Note that $h(D \cap [x_0, x_1]) \subset [x(t, t_0, x_0), x(t, t_0, x_1)]$. Therefore the relation $x_0 \ll x_1$ implies $\operatorname{Int} D \cap [x_0, x_1] \neq \emptyset$. Injectivity of h and invariance of domain implies $\operatorname{Int}[x(t, t_0, x_0), x(t, t_0, x_1)] \neq \emptyset$, which holds if and only if $x(t, t_0, x_0) \ll x(t, t_0, x_1)$.

Conversely, suppose that (3.1) is monotone, $t_0 \in J$, $x_0, x_1 \in D$ with $x_0 \leqslant x_1$ and $\phi(x_0) = \phi(x_1)$ for some $\phi \in K^*$. Since $x(t, t_0, x_0) \leqslant x(t, t_0, x_1)$ for $t \geqslant t_0$ we conclude that $\frac{\mathrm{d}}{\mathrm{d}t}\phi[x(t, t_0, x_1) - x(t, t_0, x_0)]|_{t=t_0} \geqslant 0$, or $\phi(f(t_0, x_1)) \geqslant \phi(f(t_0, x_0))$. Thus (QM) holds. □

Theorem 3.2 has been stated so as to minimize technical details concerning the domain $J \times D$ by assuming that J and D are open. In many applications, D is a closed set, for example, $D = K$ or $D = [a, b]$ where $a \ll b$. The proof can be modified to handle these (and other) cases. If $D = K$ and K is positively invariant for (3.1), the proof is unchanged because whenever $x \in D$ then $x + \epsilon v \in D$ for small positive ϵ, and because K is also positively invariant for the modified equation. If $D = [a, b]$, then the result follows by applying Theorem 3.2 to $f|J \times [[a, b]]$ and using continuity.

A set S is called *positively invariant* under (3.1) if $S \subset D$ and solutions starting in S stay in S, or more precisely:

$$(t_0, x_0) \in J \times S \quad \text{and} \quad t \in J(t_0, x_0),\ t \geqslant t_0 \quad \Longrightarrow \quad x(t, t_0, x_0) \in S.$$

It will be useful to have the following necessary and sufficient condition for invariance of K:

PROPOSITION 3.3. *The cone K is positively invariant under* (3.1) *if and only if $K \subset D$ and for each $t \in J$*

(P) $\lambda \in K^*, x \in \partial K, \lambda(x) = 0 \Longrightarrow \lambda(f(t,x)) \geqslant 0$.

PROOF. The proof that (P) implies positive invariance of K is similar to that of Theorem 3.2. Given $x_1 \in K$, we pass immediately to $x_\epsilon \gg x_1$ and the solution $y_\epsilon(t)$ of the perturbed equation defined in the proof of Theorem 3.2 and show that $y_\epsilon(t) \gg 0$ for $t_0 \leqslant t \leqslant t_1$ by an argument similar to the one used in the aforementioned proof. The result $x(t, t_0, x_1) \geqslant 0$ for $t \geqslant t_0$ is obtained by passage to the limit as $\epsilon \to 0$. The converse is also an easy modification of the converse argument given in the proof of Theorem 3.2. □

Since we will have occasion to apply (P) to systems other than (3.1), it will be convenient to refer to (P) by saying that (P) holds for $f : J \times D \to \mathbb{R}^n$ where $K \subset D$. Hypothesis (P) says that the time-dependent vector field $f(t,x)$ points into K at points $x \in \partial K$.

Let $A(t)$ be a continuous $n \times n$ matrix-valued function defined on the interval J containing t_0 and consider the linear initial value problem for the matrix solution X:

$$X' = A(t)X, \quad X(t_0) = I. \tag{3.2}$$

Observe that (P) and (QM) are equivalent for linear systems; therefore we have:

COROLLARY 3.4. *The matrix solution $X(t)$ satisfies $X(t)K \subset K$ for $t \geqslant t_0$ if and only if for all $t \in J$,* (P) *holds for the function $x \to A(t)x$. In fact,* (P) *implies that $X(t)$ maps $K \setminus \{0\}$ and* Int K *into themselves for all $t > t_0$.*

A matrix A is *K-positive* if $A(K) \subset K$. Corollary 3.4 implies that $X(t)$ is K-positive for $t \geqslant t_0$ if (P) holds.

If for every $t \in J$, there exists $\alpha \in \mathbb{R}$ such that $A + \alpha I$ is K-positive, then (P) holds for A. Indeed, if $\lambda \in K^*$ satisfies $\lambda(x) = 0$ then application of λ to $(A + \alpha I)x \geqslant 0$ yields that $\lambda(A(t)x) \geqslant 0$. The converse is false for general cones but true for polyhedral cones by Theorem 8 of Schneider and Vidyasagar [177]. See also Theorem 4.3.40 of Berman and Neumann [18]. Lemmert and Volkmann [118] give the following example of a matrix

$$A = \begin{bmatrix} 0 & 0 & 1 \\ 0 & 0 & 0 \\ 1 & 0 & 0 \end{bmatrix}$$

which satisfies (P) for the ice-cream cone above but $A + \alpha I$ is not K-positive for any α.

Recall that the domain D is *p-convex* if for every $x, y \in D$ satisfying $x \leqslant y$ the line segment joining them also belongs to D. Let $\frac{\partial f}{\partial x}(t,x)$ be continuous on $J \times D$. We say that f (or system (3.1)) is *K-cooperative* if for all $t \in J$, $y \in D$, (P) holds for the function $x \to \frac{\partial f}{\partial x}(t, y)x$. By Corollary 3.4 applied to the variational equation

$$X'(t) = \frac{\partial f}{\partial x}\bigl(t, x(t, t_0, x_0)\bigr)X, \quad X(t_0) = I$$

we conclude that if f is K-cooperative then $X(t) = \frac{\partial x}{\partial x_0}(t, t_0, x_0)$ is K-positive.

THEOREM 3.5. *Let $\frac{\partial f}{\partial x}(t, x)$ be continuous on $J \times D$. Then* (QM) *implies that f is K-cooperative. Conversely, if D is p-convex and f is K-cooperative, then* (QM) *holds.*

PROOF. Suppose that (QM) holds, $x \in D$, $h \in \partial K$, and $\phi \in K^*$ satisfies $\phi(h) = 0$. Since $x \leqslant x + \epsilon h$ and $\phi(x) = \phi(x + \epsilon h)$ for small $\epsilon > 0$, (QM) implies that $\phi(f(t, x)) \leqslant \phi(f(t, x + \epsilon h))$. Hence,

$$0 \leqslant \phi\left(\frac{f(t, x + \epsilon h) - f(t, x)}{\epsilon}\right)$$

and the desired result holds on taking the limit $\epsilon \to 0$.

Conversely, suppose that f is K-cooperative and D is p-convex. If $x, y \in D$ satisfy $x \leqslant y$ and $\phi(x) = \phi(y)$ for some $\phi \in K^*$, then either $\phi = 0$ or $y - x \in \partial K$. Consequently

$$\phi\bigl(f(t, y) - f(t, x)\bigr) = \int_0^1 \phi\left(\frac{\partial f}{\partial x}\bigl(t, sy + (1 - s)x\bigr)(y - x)\right)\mathrm{d}s \geqslant 0$$

because the integrand is nonnegative. □

If for each $(t, x) \in J \times D$ there exists α such that $(\frac{\partial f}{\partial x}(t, x) + \alpha I)$ is K-positive, then f is K-cooperative. This is implied by the remark following Corollary 3.4.

In the special case that $K = \mathbb{R}^n_+$, the cone of nonnegative vectors, it is easy to see by using the standard inner product that we may identify K^* with K. The quasimonotone hypothesis reduces to the Kamke–Müller condition [91,148]: $x \leqslant y$ and $x_i = y_i$ for some i implies $f_i(t, x) \leqslant f_i(t, y)$. This holds by taking $\phi(x) = \langle e_i, x\rangle$ (e_i is the unit vector in the x_i-direction) and noting that every $\phi \in K^*$ can be represented as a positive linear combination of these functionals. If f is differentiable, the Kamke–Müller condition implies

$$\frac{\partial f_i}{\partial x_j}(t, x) \geqslant 0, \quad i \neq j. \tag{3.3}$$

Conversely, if $\frac{\partial f}{\partial x}(t, x)$ is continuous on $J \times D$, (3.3) holds and D is p-convex, then the Kamke–Müller condition holds by an argument similar to the one used in the proof of the converse in Theorem 3.5.

Stern and Wolkowicz [206] give necessary and sufficient conditions for (P) to hold for matrix A relative to the ice-cream cone $K = \{x \in \mathbb{R}^n\colon x_1^2 + x_2^2 + \cdots + x_{n-1}^2 \leqslant x_n^2,\ x_n \geqslant 0\}$. Let Q denote the $n \times n$ diagonal matrix with first $n - 1$ entries 1 and last entry -1. Then

(QM) holds for A if and only if $QA + A^T Q + \alpha Q$ is negative semidefinite for some $\alpha \in \mathbb{R}$. Their characterization extends to other ellipsoidal cones.

3.2. *Strong monotonicity with linear systems*

In this section, all matrices are assumed to be square. Recall that the matrix A is strongly positive if $A(K \setminus \{0\}) \subset \operatorname{Int} K$. We introduce the following milder hypothesis on the matrix A, following Schneider and Vidyasagar [177]:

(ST) For all $x \in \partial K \setminus \{0\}$ there exists $\nu \in K^*$ such that $\nu(x) = 0$ and $\nu(Ax) > 0$.

The following result for the case of constant matrices was proved by Elsner [44], answering a question in [177]. Our proof follows that of Theorem 4.3.26 of Berman et al. [18].

THEOREM 3.6. *Let the linear system* (3.2) *satisfy* (P). *Then the fundamental matrix $X(t_1)$ is strongly positive for $t_1 > t_0$ if there exists s satisfying $t_0 \leqslant s \leqslant t_1$ such that* (ST) *holds for $A(s)$.*

PROOF. Observe that the set of all s such that (ST) holds for $A(s)$ is open. If the result is false, there exists $x > 0$ such that the solution of (3.2) given by $y(t) = X(t)x$ satisfies $y(t_1) \in \partial K \setminus \{0\}$. By Corollary 3.4, $y(t) > 0$ for $t \geqslant t_0$ and $y(t) \in \partial K$ for $t_0 \leqslant t \leqslant t_1$. Let $s \in (t_0, t_1]$ be such that (ST) holds for $A(s)$. Then there exists $\nu \in K^*$ such that $\nu(y(s)) = 0$ and $\nu(A(s)y(s)) > 0$. As $\nu \in K^*$ and $y(t) \in K$, $h(t) := \nu(y(t)) \geqslant 0$ for $t_0 \leqslant t \leqslant t_1$. But $h(s) = 0$ and $\frac{\mathrm{d}}{\mathrm{d}t}|_{t=s} h(t) = \nu(A(s)y(s)) > 0$ which, taken together, imply that $h(s - \delta) < 0$ for small positive δ, giving the desired contradiction. ☐

If (3.2) satisfies (P) and if $x \in \partial K$ then for all $\phi \in K^*$ such that $\phi(x) = 0$ we have $\phi(A(t)x) \geqslant 0$. Hypothesis (ST) asserts that if $x \neq 0$ then $\phi(A(t)x) > 0$ for at least one such ϕ. Berman et al. [18] refer to (ST) (they include (P) in their definition) by saying that A is strongly K-subtangential; while we do not use this terminology, our notation is motivated by it.

An example in [18] shows that (P) and (ST) are not necessary for strong positivity. Let K be the ice-cream cone $K = \{x \in \mathbb{R}^3\colon\ x_1^2 + x_2^2 \leqslant x_3^2, x_3 \geqslant 0\}$ and consider the constant coefficient system (3.2) with matrix A given by

$$A = \begin{bmatrix} 0 & 1 & 0 \\ -1 & -1 & 0 \\ 0 & 0 & 0 \end{bmatrix}.$$

An easy calculation shows that $(x_1^2 + x_2^2)' = -2x_2^2$ so it follows easily that K is positively invariant, hence (P) holds by Corollary 3.4. The solution satisfying $x(0) = (\cos(\theta), \sin(\theta), 1)^T \in \partial K$ satisfies $x(t) \in \operatorname{Int} K$ for $t > 0$ since the calculation above and the fact that $x_2(t)$ can have only simple zeros implies that $x_1^2 + x_2^2$ is strictly decreasing while x_3 remains unchanged. The linear functional ν, defined $\nu(x) :=$

$(-\cos(\theta), -\sin(\theta), 1)x$ belongs to K^* by an easy calculation and satisfies $\nu(x(0)) = 0$. It is unique, up to positive scalar multiple, with these properties because K is smooth so its positive normal at a point is essentially unique. But $\nu(Ax(0)) = \sin^2(\theta)$ vanishes if $\theta = 0, \pi$. Therefore (ST) fails although $X(t)$ is strongly positive for $t > 0$.

Theorem 3.6 leads to the following result on strong monotonicity for the nonlinear system (3.1).

LEMMA 3.7. *Assume D is p-convex, $\frac{\partial f}{\partial x}(t,x)$ is continuous on $J \times D$ and f is K-cooperative. Let $x_0, x_1 \in D$ satisfy $x_0 < x_1$ and $t > t_0$ with $t \in J(t_0,x_0) \cap J(t_0,x_1)$. If there exists y_0 on the line segment joining x_0 to x_1 and $r \in [t_0,t]$ such that* (ST) *holds for $\frac{\partial f}{\partial x}(r, x(r,t_0,y_0))$ then*

$$x(t,t_0,x_0) \ll x(t,t_0,x_1).$$

PROOF. First, observe that for y_0 on the segment it follows that $t \in J(t_0,y_0)$. We apply the formula

$$x(t,t_0,x_1) - x(t,t_0,x_0) = \int_0^1 \frac{\partial x}{\partial x_0}\big(t,t_0,sx_1 + (1-s)x_0\big)(x_1 - x_0)\,\mathrm{d}s,$$

where $X(t) = \frac{\partial x}{\partial x_0}(t,t_0,y_0)$ is the fundamental matrix for (3.2) corresponding to the matrix $A(t) = \frac{\partial f}{\partial x}(t, x(t,t_0,y_0))$. The left-hand side belongs to $K \setminus \{0\}$ if $x_0 < x_1$ by Theorems 3.5 and 3.2 but we must show it belongs to $\operatorname{Int} K$. For this to be true, it suffices that for each $t > t_0$ there exists $s \in [0,1]$ such that the matrix derivative in the integrand is strongly positive. In fact, this derivative is K-positive by Corollary 3.4 for all values of the arguments with $t \geqslant t_0$, so application of any nontrivial $\phi \in K^*$ to the integral gives a nonnegative numerical result. If there exists s as above, then the application of ϕ to the integrand gives a positive numerical result for all s' near s by continuity and Proposition 3.1 and hence the integral belongs to $\operatorname{Int} K$ by Proposition 3.1. By Theorem 3.6, $\frac{\partial x}{\partial x_0}(t,t_0,y_0)$ is strongly positive for $t > t_0$ if (ST) holds for $A(r) = \frac{\partial f}{\partial x}(r, x(r,t_0,y_0))$ for some $r \in [t_0,t]$. But this is guaranteed by our hypothesis. □

THEOREM 3.8. *D is p-convex, $\frac{\partial f}{\partial x}(t,x)$ is continuous on $J \times D$, and f is K-cooperative. Suppose for every $x_0, x_1 \in D$ with $x_0 < x_1$ and $t_0 \in J$, there exists y_0 on the line segment joining the x_i such that* (ST) *holds for $\frac{\partial f}{\partial x}(t_0,y_0)$. If $x_0, x_1 \in D$, $x_0 < x_1$, and $t > t_0$ then*

$$t \in J(t_0,x_0) \cap J(t_0,x_1) \quad \Longrightarrow \quad x(t,t_0,x_0) \ll x(t,t_0,x_1).$$

PROOF. This is an immediate corollary of Lemma 3.7. □

As the main hypothesis of Theorem 3.8 will be difficult to verify in applications, the somewhat stronger condition of irreducibility may be more useful because there is a large body of theory related to it [18,19]. We now introduce the necessary background. A closed subset F of K that is itself a cone is called *a face* of K if $x \in F$ and $0 \leqslant y \leqslant x$ (inequalities induced by K) implies that $y \in F$. For example, the faces of $K = \mathbb{R}^n_+$ are of the form $\{x \in \mathbb{R}^n_+ \colon x_i = 0,\ i \in I\}$ where $I \subset \{1, 2, \dots, n\}$. For the ice-cream cone $K = \{x \in \mathbb{R}^n \colon x_1^2 + x_2^2 + \dots + x_{n-1}^2 \leqslant x_n^2, x_n \geqslant 0\}$, the faces are the rays issuing from the origin and passing through its boundary vectors. A K-positive matrix A is *K-irreducible* if the only faces F of K for which $A(F) \subset F$ are $\{0\}$ and K. The following is a special case of Theorem 2.3.9 in Berman and Neumann [18]; see Berman and Plemmons [19] for proofs. These references contain additional related results.

THEOREM 3.9. *Let A be an $n \times n$ K-positive matrix. Then the following are equivalent*:

(i) *A is K-irreducible*;

(ii) *No eigenvector of A belongs to ∂K*;

(iii) *A has exactly one unit eigenvector in K and it belongs to* $\operatorname{Int} K$;

(iv) $(I + A)^{n-1}(K \setminus \{0\}) \subset \operatorname{Int} K$.

The famous Perron–Frobenius Theory is developed for K-positive and K-irreducible matrices in the references above. In particular, the spectral radius of A is a simple eigenvalue of A with corresponding eigenvector described in (iii) above.

Below we require the simple observation that if A is K-positive, then the adjoint A^* is K^*-positive. Indeed, if $\nu \in K^*$ then $(A^*\nu)(x) = \nu(Ax) \geqslant 0$ for all $x \in K$ so $A^*\nu \in K^*$. The next result is adapted from Theorem 4.3.17 of Berman et al. [18].

PROPOSITION 3.10. *Let A be an $n \times n$ matrix and suppose that there exists $\alpha \in \mathbb{R}$ such that $B := A + \alpha I$ is K-positive. Then B is K-irreducible if and only if* (ST) *holds for A.*

PROOF. Suppose that $B = A + \alpha I$ is K-positive and (ST) holds. If $Ax = \lambda x$ for some $\lambda \in \mathbb{R}$ and nonzero vector $x \in \partial K$ then there exists $\nu \in K^*$ such that $\nu(x) = 0$ and $\nu(Ax) > 0$. But $\nu(Ax) = \lambda \nu(x) = 0$. Consequently, no eigenvector of B belongs to ∂K so by Theorem 3.9, B is K-irreducible.

Conversely, suppose that B is K-positive and K-irreducible. Let $x \in \partial K$, $x \neq 0$ and let $\nu \in K^*$ satisfy $\nu \neq 0$ and $\nu(x) = 0$. By Theorem 3.9, $C := B + I$ has the property that C^{n-1} is strongly positive so $\nu(C^{n-1}x) > 0$. As C is K-positive, $\nu(C^r x) \geqslant 0$ for $r = 1, 2, \dots, n-1$. Because $\nu(x) = 0$, we may choose $p \in \{1, 2, \dots, n-1\}$ such that $\nu(C^p x) > 0$ but $\nu(C^{p-1}x) = 0$. Let $\tilde{\nu} = (C^*)^{p-1}\nu$. Then $\tilde{\nu} \in K^*$, $\tilde{\nu}(x) = 0$ and $\tilde{\nu}(Cx) > 0$. But then A satisfies (ST) because $\tilde{\nu}(Ax) = \tilde{\nu}(Cx) > 0$. □

Motivated by Proposition 3.10, we introduce the following hypothesis for matrix A.

(CI) There exists $\alpha \in \mathbb{R}$ such that $A + \alpha I$ is K-positive and K-irreducible.

In the special case that $K = \mathbb{R}^n_+$, $n \geqslant 2$, matrix A satisfies (CI) if and only if $a_{ij} \geqslant 0$ for $i \neq j$ and there is no permutation matrix P such that

$$P^T A P = \begin{bmatrix} B & 0 \\ C & D \end{bmatrix},$$

where B and D are square. This is equivalent to the assertion that the incidence graph of A is strongly connected. See Berman and Plemmons [19].

The following is an immediate consequence of Theorem 3.8.

COROLLARY 3.11. *D is p-convex, $\frac{\partial f}{\partial x}(t,x)$ is continuous on $J \times D$ and f is K-cooperative. Suppose that for every $x_0, x_1 \in D$ with $x_0 < x_1$ and $t_0 \in J$, there exists y_0 on the line segment joining the x_i such that* (CI) *holds for $\frac{\partial f}{\partial x}(t_0, y_0)$. If $x_0, x_1 \in D$, $x_0 < x_1$, and $t > t_0$ then*

$$t \in J(t_0, x_0) \cap J(t_0, x_1) \quad \Longrightarrow \quad x(t, t_0, x_0) \ll x(t, t_0, x_1).$$

PROOF. If (CI) holds then, by Proposition 3.10, (ST) holds for $\frac{\partial f}{\partial x}(t,x)$, so the conclusion follows from Theorem 3.8. □

Corollary 3.11 is an improvement of the restriction of Theorem 10 of Kunze and Siegel [111] to the case that K has nonempty interior; their results also treat the case that K has empty interior in $\mathbb{R}^n$ but nonempty interior in some subspace of $\mathbb{R}^n$. Walter [228] gives a sufficient condition for strong monotonicity relative to $K = \mathbb{R}^n_+$ which does not require f to be differentiable.

For polyhedral cones it can be shown that matrix A satisfies (P) and (ST) if and only if there exists $\alpha \in \mathbb{R}$ such that $A + \alpha I$ is K-positive and K-irreducible. See Theorem 4.3.40 of Berman et al. [18]. For the case of polyhedral cones, therefore, Corollary 3.11 and Theorem 3.8 are equivalent.

3.3. *Autonomous K-competitive and K-cooperative systems*

Our focus now is on the autonomous system of ordinary differential equations

$$x' = f(x), \tag{3.4}$$

where f is a vector field on an open subset $D \subset \mathbb{R}^n$; all vector fields are assumed to be continuously differentiable. We change our notation slightly to conform to more dynamical notation, denoting $x(t, 0, x_0)$ by $\Phi_t(x)$, where Φ denotes the dynamical system (= local flow) in D generated by f discussed in Section 1. The notation $\Phi_t(x)$ carries the tacit assumption that $t \in I_x$, the open interval in $\mathbb{R}$ containing the origin on which the trajectory of x under Φ is defined. The *positive semiorbit* (respectively, (*negative semiorbit*) of x is $\gamma^+(x) := \{\Phi_t(x)\colon t \in t \geqslant 0\}$ (respectively, $\gamma^-(x) := \{\Phi_t(x)\colon t \leqslant 0\}$). The limit sets of x can be defined as

$$\omega(x) = \bigcap_{t \geqslant 0} \overline{\bigcup_{\tau \geqslant t} \Phi_\tau(x)}, \qquad \alpha(x) = \bigcap_{t \leqslant 0} \overline{\bigcup_{\tau \leqslant t} \Phi_\tau(x)}.$$

We call f and Eq. (3.4) *K-competitive* in D if the time-reversed system

$$x' = -f(x)$$

is K-cooperative. When K is the standard cone $\mathbb{R}^n_+$, f is competitive if and only if $\partial f_i/\partial x_j \leqslant 0$ for $i \neq j$. Therefore if f is K-competitive with local flow Φ, then $-f$ is K-cooperative with local flow $\widetilde{\Phi}$, where $\widetilde{\Phi}_t(x) = \Phi_{-t}(x)$; and conversely. Thus time-reversal changes K-competitive systems into K-cooperative ones, and vice-versa. This fact will be exploited repeatedly below.

In the remainder of Section 3 we assume $\mathbb{R}^n$ is ordered by a cone $K \subset \mathbb{R}^n$ with nonempty interior.

A map is *locally monotone* if every point in its domain has a neighborhood on which the map is monotone. A local flow or local semiflow Φ is locally monotone if Φ_t is a locally monotone map for all $t > 0$. *Locally strongly monotone* is defined similarly.

THEOREM 3.12. *Let f be a K-cooperative vector field in an open set $D \subset \mathbb{R}^n$, generating the local flow Φ. Then Φ is locally monotone, and monotone when D is p-convex.*

PROOF. If D is p-convex, monotonicity follows from Theorem 3.2 (with $f(t,x) := f(x)$). Suppose D is not p-convex. Denote the domain of Φ_t by D_t.

We first claim: For every $p \in D$ there exists $\tau > 0$ and a neighborhood $N \subset D_\tau$ such that $\Phi_t|N$ is monotone if $t \in [0,\tau]$. But this is obvious since by restricting f to a p-convex neighborhood of p, we can use Theorem 3.2.

Now fix $p \in D$ and let $J(0,p) \cap [0,\infty) = [0,r)$, $0 < r \leqslant \infty$. Let I_p be the set of all nonnegative $s \in [0,r)$ such that there is a neighborhood U_s of p, contained in D_s, such that $\Phi_t|U_s$ is monotone for each $t \in [0,s]$. The previous claim implies that $[0,\tau] \subset I_p$ and, by its definition, I_p is an interval. Furthermore, straightforward applications of the previous claim establish that I_p is both an open and a closed subset of $[0,r)$. It follows that $I_p = [0,r)$. □

The next theorem gives a sufficient condition for strong monotonicity. Define $G(f)$ to be the set of $x \in D$ such that (ST) holds for $A = f'(x)$. Note that $x \in G(f)$ provided (CI) holds for $A = f'(x)$, by Proposition 3.10. If $K = \mathbb{R}^n_+$, a sufficient condition for $x \in G(f)$ is that $f'(x)$ is an irreducible matrix with nonnegative off-diagonal entries.

THEOREM 3.13. *Let f be a K-cooperative vector field in an open set $D \subset \mathbb{R}^n$, generating the local flow Φ. Assume $D \setminus G(f)$ does not contain any totally ordered line segment* (*which holds when $D \setminus G(f)$ is zero dimensional*). *Then Φ is locally strongly monotone, and strongly monotone when D is p-convex.*

PROOF. Suppose D is p-convex, in which case Φ is monotone by from Theorem 3.2. By Theorem 3.8, Φ is strongly monotone.

When D is not p-convex, Φ is locally monotone by Theorem 3.12, and the previous paragraph implies Φ is locally strongly monotone. □

The proof of Theorem 3.13 can be adapted to cover certain nonopen domains D, such as an order interval, a closed halfspace, and the cone K; see the discussion following the proof of Theorem 3.2.

Theorem 3.8 implies that Φ is strongly monotone provided D is p-convex and f satisfies the autonomous version of condition (ST) of Section 3.2, namely:

(ST*) For all $u \in D, x \in \partial K \setminus \{0\}$ there exists $\nu \in K^*$ such that $\nu(x) = 0$ and $\nu(f'(u)x) > 0$.

Without p-convexity of D, condition (ST*) yields local strong monotonicity.

3.4. *Dynamics of cooperative and competitive systems*

We continue to assume $\mathbb{R}^n$ is ordered by a cone K having nonempty interior; all notions involving order refer to that defined by K. For this section, the terms "competitive" and "cooperative" are tacitly understood to mean "K-competitive" and "K-cooperative," and monotonicity refers to the ordering defined by K.

We first apply results from Section 2 to obtain a generic stable convergence theorem for cooperative vector fields.

Let Φ denote the local flow generated by a vector field f on $D \subset \mathbb{R}^n$. We assume D is p-convex throughout this section without further mention. When $\Phi_t(x)$ is defined for all $(t, x) \in [0, \infty) \times D$, as when all positive semiorbits have compact closure in D, the corresponding positive local semiflow Φ^+ is a semiflow. To Φ we associate C, S and E, denoting respectively the sets of convergent, stable and equilibrium points for Φ^+.

THEOREM 3.14. *Let f be a cooperative vector field on an open set $D \subset \mathbb{R}^n$, generating a local flow Φ such that*:

(a) *Every positive semiorbit of Φ has compact closure in D*;

(b) *Condition* (ST*) *above is satisfied, and $D = AC \cup BC$.*

Then Φ has the following properties:

(i) *$C \cap S$ contains a dense open subset of D, consisting of points whose trajectories converge to equilibria*;

(ii) *If E is compact there is a stable equilibrium, and an asymptotically stable equilibrium when E is finite.*

PROOF. Assumption (ST*) makes Φ strongly monotone. The hypothesis of Theorem 2.26, with $X = D$, is fulfilled: D is normally ordered and $D = BC \cup AC$. Therefore Theorem 2.26 implies the conclusion. □

Theorem 3.14, like Theorem 3.13, holds for some more general domains D, including relatively open subsets of V where V denotes a closed halfspace, a closed order interval, or the cone K.

One of the main results of this subsection is that n-dimensional competitive and cooperative systems behave like general systems of one less dimension. Theorems 3.21 and 3.22 illustrate this principle for $n = 2$ in a very strong form. In higher dimensions the principle holds for compact limit sets. The key tool in proving this is the following result due to Hirsch [67]:

THEOREM 3.15. *A limit set of a competitive or cooperative system cannot contain two points related by* $\ll$.

PROOF. By time reversal, if necessary, we assume the system is cooperative, hence the local flow is monotone. Now apply Proposition 1.10. □

A periodic orbit of a competitive or cooperative system is a limit set and consequently it cannot contain two points related by $\ll$. The following sharper result will be useful later:

PROPOSITION 3.16. *Nontrivial periodic orbit of a competitive or cooperative system cannot contain two points related by* $<$.

PROOF. By time-reversal we assume the system is cooperative, and in this case the conclusion follows from Proposition 1.10. □

Let Φ, Ψ be flows in respective spaces A, B. We say Φ and Ψ are *topologically equivalent* if there is a homeomorphism $Q: A \to B$ that is a conjugacy between them, i.e., $Q \circ \Phi_t = \Psi_t \circ Q$ for all $t \in \mathbb{R}$. The relationship of topological equivalence is an equivalence relation on the class of flow; it formalizes the notion of "having the same qualitative dynamics."

A system of differential equations $y' = F(y)$, defined on $\mathbb{R}^k$, is called *Lipschitz* if F is Lipschitz. That is, there exists $K > 0$ such that $|F(y_1) - F(y_2)| \leqslant K|y_1 - y_2|$ for all $y_1, y_2 \in \mathbb{R}^k$. With these definitions, we can state a result of Hirsch [67] that follows directly from Theorem 3.15.

THEOREM 3.17. *The flow on a compact limit set of a competitive or cooperative system in* $\mathbb{R}^n$ *is topologically equivalent to a flow on a compact invariant set of a Lipschitz system of differential equations in* $\mathbb{R}^{n-1}$.

PROOF. Let L be the limit set, $v \gg 0$ be a unit vector and let H_v be the hyperplane orthogonal to v, i.e, $H_v := \{x\colon \langle x, v\rangle = 0\}$. The orthogonal projection Q onto H_v is given by $Qx = x - \langle x, v\rangle v$. By Theorem 3.15, Q is one-to-one on L (this could fail only if L contains two points that are related by $\ll$). Therefore, Q_L, the restriction of Q to L, is a Lipschitz homeomorphism of L onto a compact subset of H_v. We argue by contradiction to establish the existence of $m > 0$ such that $|Q_L x_1 - Q_L x_2| \geqslant m|x_1 - x_2|$ whenever $x_1 \neq x_2$ are points of L. If this were false, then there exists sequences $x_n, y_n \in L$, $x_n \neq y_n$ such that

$$\frac{|Q(x_n) - Q(y_n)|}{|x_n - y_n|} = \frac{|(x_n - y_n) - v\langle v, x_n - y_n\rangle|}{|x_n - y_n|} \to 0$$

as $n \to \infty$. Equivalently, $|w_n - v\langle v, w_n\rangle| \to 0$ as $n \to \infty$ where $w_n = x_n - y_n/|x_n - y_n|$. We can assume that $w_n \to w$ as $n \to \infty$ where $|w| = 1$. Then, $w = v\langle v, w\rangle$ and therefore, $\langle v, w\rangle^2 = 1$ so $w = \pm v$. But then $x_n - y_n/|x_n - y_n| \to \pm v$ as $n \to \infty$ and this implies that $x_n \ll y_n$ or $y_n \ll x_n$ for all large n, contradicting Theorem 3.15. Therefore, Q_L^{-1} is Lipschitz on $Q(L)$. Since L is a limit set, it is an invariant set for (3.4). It follows that the dynamical system restricted to L can be modeled on a dynamical system in H_v. In fact, if $y \in Q(L)$ then $y = Q_L(x)$ for a unique $x \in L$ and $\Psi_t(y) \equiv Q_L(\Phi_t(x))$ is a dynamical system on $Q(L)$ generated by the vector field

$$F(y) = Q_L\bigl(f\bigl(Q_L^{-1}(y)\bigr)\bigr)$$

on $Q(L)$. According to McShane [137], a Lipschitz vector field on an arbitrary subset of H_v can be extended to a Lipschitz vector field on all of H_v, preserving the Lipschitz constant. It follows that F can be extended to all of H_v as a Lipschitz vector field. It is easy to see that $Q(L)$ is an invariant set for the latter vector field. We have established the topological equivalence of the flow Φ on L with the flow Ψ on $Q(L)$. $Q(L)$ is a compact invariant set for the $(n-1)$-dimensional dynamical system on H_v generated by the extended vector field. □

A consequence of Theorem 3.17 is that the flow on a compact limit set, L, of a competitive or cooperative system shares common dynamical properties with the flow of a system of differential equations in one less dimension, restricted to the compact, connected invariant set $Q(L)$. Notice, however, that L may be the limit set of a trajectory not in L, and therefore $Q(L)$ need not be a limit set.

On the other hand, the flow Ψ in a compact limit sets enjoys the topological property of *chain recurrence*, due to Conley [31,30], which will be important in the next subsection. The definition is as follows. Let A be a compact invariant set for the flow Φ. Given two points z and y in A and positive numbers ϵ and t, an (ϵ, t)-chain from z to y in A is an ordered set

$$\{z = x_1, x_2, \dots, x_{m+1} = y; t_1, t_2, \dots, t_m\}$$

of points $x_i \in A$ and times $t_i \geqslant t$ such that

$$\bigl|\Phi_{t_i}(x_i) - x_{i+1}\bigr| < \epsilon, \quad i = 1, 2, \dots, m. \tag{3.5}$$

A is *chain recurrent* for Φ if for every $z \in A$ and for every $\epsilon > 0$ and $t > 0$, there is an (ϵ, t)-chain from z to z in A.

Conley proved that when A is compact and connected, a flow Φ in A is chain recurrent if and only if there are no attractors. This useful condition can be stated as follows: For every proper nonempty compact set $S \subset A$ and all $t > 0$, there exists $s > t$ such that $\Phi_s(S) \not\subset \operatorname{Int} S$.

Compactness of A implies that chain recurrence of the flow in A is independent of the metric, and thus holds for any topologically equivalent flow.

It is intuitively clear that, as Conley proved, flows in compact alpha and omega limit sets are chain recurrent. Indeed, orbit segments of arbitrarily long lengths through point x repeatedly pass near any point of $\omega(x) \cup \alpha(x)$. Of course these segments do not necessarily belong to $\omega(x)$; but by taking suitable limits of points in these segments, one can find enough (ϵ, t)-chains in $\omega(x)$ and $\alpha(x)$ to prove the flows in these sets chain recurrent. For a rigorous proof, see Smith [194].

3.5. *Smale's construction*

Smale [182] showed that it is possible to embed essentially arbitrary dynamics in a competitive or cooperative irreducible system. His aim was to warn population modelers that systems designed to model competition could have complicated dynamics. His result is also very useful for providing counterexamples to conjectures in the theory of monotone dynamics, since by time reversal his systems are cooperative. In this section, competitive and cooperative are with respect to the usual cone.

Smale constructed special systems of Kolmogorov type

$$x_i' = x_i M_i(x), \quad 1 \leqslant i \leqslant n, \tag{3.6}$$

in $\mathbb{R}^n_+$ where the M_i are smooth functions satisfying

$$\frac{\partial M_i}{\partial x_j} < 0 \tag{3.7}$$

for all i, j; all sums are understood to be from 1 to n. We refer to such systems as *totally competitive*. They are simple models of competition between n species, where M_i is interpreted as the *per capita* growth rate of species i.

Smale's object was to choose the M_i so that the standard $(n-1)$-simplex $\Sigma_n = \{x \in \mathbb{R}^n_+\colon \sum x_i = 1\}$ is an attractor in which arbitrary dynamics may be specified.

In order to generate a dynamical system on Σ_n, let H denote the tangent space to Σ_n, that is, $H = \{x \in \mathbb{R}^n\colon \sum x_i = 0\}$, and let $h : \Sigma_n \to H$ be a smooth vector field on Σ_n, meaning that all partial derivatives of h exist and are continuous on Σ_n. We also assume that $h = (h_1, h_2, \ldots, h_n)$ has the form $h_i = x_i g_i(x)$ where the g_i are smooth functions on Σ_n. Then the differential equation

$$x_i' = h_i(x), \quad 1 \leqslant i \leqslant n \tag{3.8}$$

generates a flow in $\mathbb{R}^n_+$ that leaves Σ_n invariant. The form of the h_i ensures that if $x_i(0) = 0$, then $x_i(t) \equiv 0$ so each lower dimensional simplex forming part of the boundary of Σ_n is invariant.

The goal is to construct a competitive system of the form (3.6) satisfying (3.7) such that its restriction to Σ_n is equivalent to (3.8). Let $p : [0, \infty) \to \mathbb{R}_+$ have continuous derivatives of all orders, be identically 1 in a neighborhood of $s = 1$, and vanish outside the interval $[1/2, 3/2]$. As g is a smooth vector field on Σ_n, it has a smooth extension to $\mathbb{R}^n_+$ which we denote by g in order to conserve notation. An example of such an extension is the map $x \mapsto P(\sum x_j) g(x / \sum x_j)/P(1)$, where $P(u) = \int_0^u p(s)\, \mathrm{d}s$.

For $\eta > 0$, define

$$M_i(x) = 1 - S(x) + \eta p\Bigl(\sum x_j\Bigr) g_i(x), \quad 1 \leqslant i \leqslant n.$$

Then (3.7) holds for sufficiently small η since $p(\sum x_j)$ vanishes identically outside a compact subset of $\mathbb{R}^n_+$. Consider the system (3.6) with M as above. $\mathbb{R}^n_+$ is positively invariant; and the function $S(x) = \sum_i x_i$, evaluated along a solution $x(t)$ of (3.6), satisfies

$$\frac{\mathrm{d}}{\mathrm{d}t} S\bigl(x(t)\bigr) = S\bigl(x(t)\bigr)\bigl[1 - S\bigl(x(t)\bigr)\bigr]$$

since $\sum x_i g_i(x) = \sum h_i(x) = 0$. Consequently $\varSigma_n$, which is $S^{-1}(1) \cap \mathbb{R}^n_+$, is positively invariant. Moreover if $x(0) \in \mathbb{R}^n_+$ then $S(x(0)) \geqslant 0$. This implies $S(x(t)) \to 1$ as $t \to \infty$, unless $x(t) \equiv 0$, and $\varSigma_n$ attracts all nontrivial solutions of (3.6) in $\mathbb{R}^n_+$. Restricted to $\varSigma_n$, (3.6) becomes

$$x_i' = \eta h_i(x), \quad 1 \leqslant i \leqslant n.$$

Therefore the dynamics of (3.6) restricted to $\varSigma_n$ is equivalent, up to a change in time scale, to the dynamics generated by (3.8).

As noted above, Smale's construction has implications for cooperative and irreducible systems since the time-reversed system corresponding to (3.6) is cooperative and irreducible in $\operatorname{Int}\mathbb{R}^n_+$. Time-reversal makes the simplex a repellor for a cooperative system $\varPhi$ in $\mathbb{R}^n_+$. Therefore every invariant set in the simplex is unstable for $\varPhi$. Each trajectory of $\varPhi$ that is not in the simplex is attracted to the equilibrium at the origin or to the virtual equilibrium at ∞. The simplex is the common boundary between the basins of attraction of these two equilibria.

3.6. *Invariant surfaces and the carrying simplex*

It turns out that the essential features of Smale's seemingly very special construction are found in a large class of totally competitive Kolmogorov systems

$$x_i' = x_i M_i(x), \quad x \in \mathbb{R}^n_+. \tag{3.9}$$

Here and below i and j run from 1 to n. Let $\varPhi$ denote the corresponding local flow. The *unit* $(n-1)$ *simplex* is $\varDelta^{n-1} := \{x \in \mathbb{R}^n_+ \colon \sum x_i = 1\}$.

THEOREM 3.18. *Assume* (3.9) *satisfies the following conditions*:
(a) $\frac{\partial M_i}{\partial x_j} < 0$;
(b) $M_i(0) > 0$;
(c) $M_i(x) < 0$ *for* $|x|$ *sufficiently large*.
Then there exists an invariant compact hypersurface $\varSigma \subset \mathbb{R}^n_+$ *such that*
(i) $\varSigma$ *attracts every point in* $\mathbb{R}^n_+ \setminus \{0\}$;
(ii) $\varSigma \cap \operatorname{Int}\mathbb{R}^n_+$ *is a locally Lipschitz submanifold*;
(iii) $\varSigma \cap \operatorname{Int}\mathbb{R}^n_+$ *is transverse to every line that is parallel to a nonnegative vector and meets* $\varSigma \cap \operatorname{Int}\mathbb{R}^n_+$;
(iv) $\varSigma$ *is unordered*;

(v) *Radial projection defines a homeomorphism* $h : \Sigma \to \Delta^{n-1}$ *whose inverse is locally Lipschitz on the open* $(n-1)$*-cell* $\Delta^{n-1} \cap \operatorname{Int} \mathbb{R}^n_+$. *There is a flow* Ψ *on* Δ^{n-1} *such that* $\Phi_t|\Sigma = h \circ \Phi_t \circ h^{-1}$.

COROLLARY 3.19. *If* $n = 3$, *every periodic orbit in* $\mathbb{R}^3_+$ *bounds an unordered invariant disk.*

Assumption (a) is the condition of total competition; (b) and (c) have plausible biological interpretations. The attracting hypersurface Σ, named the *carrying simplex* by M. Zeeman, is analogous to the carrying capacity K in the one-dimensional logistic equation $\mathrm{d}x/\mathrm{d}t = rx(K-x)$. One can define Σ either as the boundary of the set of points whose alpha limit set is the origin, or as the boundary of the compact global attractor. These sets coincide if and only if Σ is unique, in which case it uniformly attracts every compact set in $\mathbb{R}^n_+ \setminus \{0\}$. Uniqueness holds under mild additional assumptions on the maps M_i (Wang and Jiang [230]). The geometry, smoothness and dynamics of carrying simplices have been investigated by Benaïm [14], Brunovsky [21], Miercyński [140,143,141], Tineo [220], van den Driessche and M. Zeeman [223], Wang and Jiang [230], E. Zeeman [239], E. Zeeman and M. Zeeman [240–242], M. Zeeman [243].

Theorem 3.18 is proved in Hirsch [72] using a general existence theorem for invariant hypersurfaces, of which the following is a generalization:

THEOREM 3.20. *Let* Φ *be a strongly monotone local flow in a p-convex open set* $D \subset \mathbb{R}^n$. *If* $L \subset D$ *is a nonempty compact unordered invariant set,* L *lies in an unordered invariant hypersurface* M *that is a locally Lipschitz submanifold.*

IDEA OF PROOF. Define U to be the set of $x \in D$ such that $\Phi_t(x) \gg y$ for some $t > 0$, and some $y \in L$. Continuity implies U is open, and it is nonempty since it contains $z \in D$ where $z > y \in L$. It can be shown that the lower boundary of U in D (Section 1.1) is a hypersurface with the required properties, by arguments analogous to the proof of Theorem 3.17. □

3.7. *Systems in* $\mathbb{R}^2$

Cooperative and competitive systems in $\mathbb{R}^2$ have particularly simple dynamics. Versions of the following result were proved in Hirsch [67], Theorem 2.7 and Smith [194], Theorem 3.2.2. It is noteworthy that in the next two theorems Φ does not need to be monotone, only locally monotone; hence p-convexity of D is not needed.

THEOREM 3.21. *Let* $D \subset \mathbb{R}^2$ *be an open set and* $g : D \to \mathbb{R}^2$ *a vector field that is cooperative or competitive for the standard cone. Let* $y(t)$ *a nonconstant trajectory defined on an open interval* $I \subset \mathbb{R}$ *containing* 0. *Then there exists* $t_* \in I$ *such that each coordinate* $y_i(t)$ *is nonincreasing or nondecreasing on each connected component of* $I \setminus \{t_*\}$.

PROOF. It suffices to prove that $y_i'(t)$ can change sign at most once. We assume g is cooperative, otherwise reversing time. Let Φ be local flow of g and set $X(t,x) = \frac{\partial \Phi}{\partial x}(t,x)$. The matrix-valued function $X(t,x)$ satisfies the variational equation

$$\frac{\partial}{\partial t} X(t,x) = \frac{\partial g}{\partial x}\bigl(\Phi(t,x)\bigr) \cdot X(t,x), \qquad X(0,x) = I.$$

Cooperativity and Corollary 3.4 show that $X(t,x)$ has nonnegative entries for $t \geqslant 0$, i.e., matrix multiplication by $X(t,x)$ preserves the standard cone. The tangent vector $y'(t)$ to the curve $y(t)$, being a solution of the variational equation, satisfies $y'(t) = X(t, y(0))y'(0)$. Nonnegativity of $X(t,x)$ implies that if $y'(t_0)$ lies in the first or third quadrants, then $y'(t)$ stays in the same quadrant, and hence its coordinates have constant sign, for $t > t_0$. On the other hand if $y'(t)$ for $t \geqslant t_0$ is never in the first or third quadrants, its coordinates again have constant sign. (Note that $y'(t)$ cannot transit directly between quadrants 1 and 3, or 2 and 4, since it cannot pass through the origin.) We have shown that there is at most one $t_0 \in I$ at which $y'(t)$ changes quadrants. If such a t_0 exists, set $t_* = t_0$; otherwise let $t_* \in I$ be arbitrary. □

Variants of the next result have been proved many times for Kolmogorov type population models (Albrecht et al. [1], Grossberg [53], Hirsch and Smale [80], Kolmogorov [97], Rescigno and Richardson [168], Selgrade [178]).

THEOREM 3.22. *Let g be a K-cooperative or K-competitive vector field in a domain $D \subset \mathbb{R}^2$. If $\gamma^+(x)$ (respectively, $\gamma^-(x)$) has compact closure in D, then $\omega(x)$ (respectively, $\alpha(x)$) is a single equilibrium.*

PROOF. For the standard cone, denoted here by P, this follows from Theorem 3.21. The general case follows by making a linear coordinate change $y = Tx$ mapping K onto the standard cone. Here T is any linear transformation that takes a basis for $\mathbb{R}^2$ contained in ∂P into the standard basis, which lies in ∂K. Then we have $u \leqslant_K v$ if and only if $Tu \leqslant_P Tv$; in other words, T is an order isomorphism. It follows that the system $x' = g(x)$ is K-cooperative (respectively, K-competitive) if and only if the system $y' = h(y) := Tg(T^{-1}y)$ is P-cooperative (respectively, P-competitive). Therefore T is a conjugacy between the local flows Φ, Ψ of the two dynamical systems, that is, $T \circ \Phi_t = \Psi_t \circ T$. Consequently the conclusion for P, proved above, implies the conclusion for K. □

3.8. *Systems in $\mathbb{R}^3$*

The following Poincaré–Bendixson theorem for three-dimensional cooperative and competitive systems is the most notable consequence of Theorem 3.17. It was proved by Hirsch [76] who improved earlier partial results [67,187]. The following result from Smith [194] holds for arbitrary cones $K \subset \mathbb{R}^3$ with nonempty interior:

THEOREM 3.23. *Let g be a K-cooperative or K-competitive vector field in a p-convex domain $D \subset \mathbb{R}^3$. Then a compact limit set of g that contains no equilibrium points is a periodic orbit.*

PROOF. Let Φ denote the flow of the system, and L the limit set. By Theorem 3.17, the restriction of Φ to L is topologically equivalent to a flow Ψ, generated by a Lipschitz planar vector field, restricted to the compact, connected, chain recurrent invariant set $Q(L)$. Since L contains no equilibria neither does $Q(L)$. The Poincaré–Bendixson theorem implies that $Q(L)$ consists of periodic orbits and, possibly, entire orbits whose omega and alpha limit sets are periodic orbits contained in $Q(L)$. The chain recurrence of Ψ on $Q(L)$ will be exploited to show that $Q(L)$ consists entirely of periodic orbits.

Let $z \in Q(L)$ and suppose that z does not belong to a periodic orbit. Then $\omega(z)$ and $\alpha(z)$ are distinct periodic orbits in $Q(L)$. Let $\omega(z) = \gamma$ and suppose for definiteness that z belongs to the interior component, V, of $\mathbb{R}^2 \setminus \gamma$ so that $\Psi_t(z)$ spirals toward γ in V. The other case is treated similarly. Then γ is asymptotically stable relative to V. Standard arguments using transversals imply the existence of compact, positively invariant neighborhoods U_1 and U_2 of γ in V such that $U_2 \subset \mathrm{Int}_V U_1$, $z \notin U_1$ and there exists $t_0 > 0$ for which $\Psi_t(U_1) \subset U_2$ for $t \geqslant t_0$. Let $\epsilon > 0$ be such that the 2ϵ-neighborhood of U_2 in D is contained in U_1. Choose t_0 larger if necessary such that $\Psi_t(z) \in U_2$ for $t \geqslant t_0$. This can be done since $\omega(z) = \gamma$. Then any (ϵ, t_0)-chain in $Q(L)$ beginning at $x_1 = z$ satisfies $\Psi_{t_1}(x_1) \in U_2$ and, by (3.5) and the fact that the 2ϵ-neighborhood of U_2 is contained in U_1, it follows that $x_2 \in U_1$. As $t_2 > t_0$, it then follows that $\Psi_{t_2}(x_2) \in U_2$ and (3.5) again implies that $x_3 \in U_1$. Continuing this argument, it is evident that the (ϵ, t_0)-chain cannot return to z. There can be no (ϵ, t_0)-chain in $Q(L)$ from z to z and therefore we have contradicted that $Q(L)$ is chain recurrent. Consequently, every orbit of $Q(L)$ is periodic. Since $Q(L)$ is connected, it is either a single periodic orbit or an annulus consisting of periodic orbits. It follows that L is either a single periodic orbit or a cylinder of periodic orbits.

To complete the proof we must rule out the possibility that $Q(L)$ consists of an annulus of periodic orbits. We can assume that the system is cooperative. The argument will be separated into two cases: $L = \omega(x)$ or $L = \alpha(x)$.

If $L = \omega(x)$ consists of more than one periodic orbit then $Q(L)$ is an annulus of periodic orbits in the plane containing an open subset O. Then there exists $t_0 > 0$ such that $Q(\Phi_{t_0}(x)) \in O$. Let y be the unique point of L such that $Q(y) = Q(\Phi_{t_0}(x))$. $y = \Phi_{t_0}(x)$ cannot hold since this would imply that L is a single periodic orbit so it follows that either $y \ll \Phi_{t_0}(x)$ or $\Phi_{t_0}(x) \ll y$. Suppose that the latter holds, the argument is similar in the other case. Then there exists $t_1 > t_0$ such that $\Phi_{t_1}(x)$ is so near y that $\Phi_{t_0}(x) \ll \Phi_{t_1}(x)$. But then the Convergence Criterion from Chapter 1 implies that $\Phi_t(x)$ converges to equilibrium, a contradiction to our assumption that L contains no equilibria. This proves the theorem in this case.

If $L = \alpha(x)$ and $Q(L)$ consists of an annulus of periodic orbits, let $C \subset L$ be a periodic orbit such that $Q(L)$ contains C in its interior. $Q(C)$ separates $Q(L)$ into two components. Fix a and b in $L \setminus C$ such that $Q(a)$ and $Q(b)$ belong to different components of $Q(L) \setminus Q(C)$. Since $\Phi_t(x)$ repeatedly visits every neighborhood of a and b as $t \to -\infty$, $Q(\Phi_t(x))$ must cross $Q(C)$ at a sequence of times $t_k \to -\infty$. Therefore, there exist $z_k \in C$ such that $Q(z_k) = Q(\Phi_{t_k}(x))$ and consequently, as in the previous case, either $z_k \ll \Phi_{t_k}(x)$

or $\Phi_{t_k}(x) \ll z_k$ holds for each k. Passing to a subsequence, we can assume that either $z_k \ll \Phi_{t_k}(x)$ holds for all k or $\Phi_{t_k}(x) \ll z_k$ holds for all k. Assume the latter, the argument is essentially the same in the other case. We claim that for every $s < 0$ there is a point $w \in C$ such that $\Phi_s(x) > w$. For if $t_k < s$ then

$$\Phi_s(x) = \Phi_{s-t_k} \circ \Phi_{t_k}(x) < \Phi_{s-t_k}(z_k) \in C.$$

If $y \in L$ then $\Phi_{s_n}(x) \to y$ for some sequence $s_n \to -\infty$. By the claim, there exists $w_n \in C$ such that $\Phi_{s_n}(x) > w_n$. Passing to a subsequence if necessary, we can assume that $w_n \to w \in C$ and $y \geqslant w$. Therefore, every point of L is related by $\leqslant$ to some point of C.

The same reasoning applies to every periodic orbit $C' \subset L$ for which $Q(C')$ belongs to the interior of $Q(L)$: either every point of L is $\leqslant$ some point of C' or every point of L is $\geqslant$ some point of C'. Since there are three different periodic orbits in L whose projections are contained in the interior of $Q(L)$, there will be two of them for which the same inequality holds between points of L and points of the orbit. Consider the case that there are two periodic orbits C_1 and C_2 such that every point of L is $\leqslant$ some point of C_1 and $\leqslant$ some point of C_2. The case that the opposite relations hold is treated similarly. If $u \in C_1$ then it belongs to L so we can find $w \in C_2$ such that $u < w$ (equality can't hold since the points belong to different periodic orbits). But $w \in L$ so we can find $z \in C_1$ such that $w < z$. Consequently, $u, z \in C_1$ satisfy $u < z$, a contradiction to Proposition 3.16. This completes the proof. □

A remarkable fact about three-dimensional competitive or cooperative systems on suitable domains is that the existence of a periodic orbit implies the existence of an equilibrium point inside a certain semi-invariant closed ball having the periodic orbit on its boundary. Its primary use is to locate equilibria, or conversely, to exclude periodic orbits. The construction below is adapted from Smith [187,194] where the case $K = \mathbb{R}^3_+$ was treated; here we treat the general case that K has nonempty interior. The terms "competitive" and "cooperative" will be used to mean K-competitive and K-cooperative for brevity. A related result appears in Hirsch [75]. Throughout the remainder of this section, the system is assumed to be defined on a p-convex subset D of $\mathbb{R}^3_+$.

We can assume the system is competitive. Let γ denote the periodic orbit and assume that there exist p, q with $p \ll q$ such that

$$\gamma \subset [p, q] \subset D. \tag{3.10}$$

Define

$$B = \{x \in \mathbb{R}^3\colon x \text{ is not related to any point } y \in \gamma\} = (\gamma + K)^{\mathrm{c}} \cap (\gamma - K)^{\mathrm{c}}.$$

Here we use the notation A^{c} for the complement of the subset A in $\mathbb{R}^3$. Observe that in defining B we ignored the domain D of (3.4), viewing γ as a subset of $\mathbb{R}^3$. Another way to define B is to express its complement as $B^{\mathrm{c}} = (\gamma + K) \cup (\gamma - K)$.

A 3-*cell* is a subset of $\mathbb{R}^3$ that is homeomorphic to the open unit ball.

THEOREM 3.24. *Let γ be a nontrivial periodic orbit of a competitive system in $D \subset \mathbb{R}^3$ and suppose that* (3.10) *holds. Then B is an open subset of $\mathbb{R}^3$ consisting of two connected components, one bounded and one unbounded. The bounded component, $B(\gamma)$, is a* 3*-cell contained in $[p,q]$. Furthermore, $B(\gamma)$ is positively invariant and its closure contains an equilibrium.*

Combining this result with Theorem 3.23 leads to the following dichotomy from Hirsch [75].

COROLLARY 3.25. *Assume the domain $D \subset \mathbb{R}^3$ of a cooperative or competitive system contains $[p,q]$ with $p \ll q$. Then one of the following holds*:

(i) *$[p,q]$ contains an equilibrium*;

(ii) *the forward and backward semi-orbits of every point of $[p,q]$ meet $D \setminus [p,q]$.*

PROOF. We take the system to be competitive, otherwise reversing time. Assume (ii) is false. Then $[a,b]$ contains a compact limit set L. If L is not a cycle, it contains an equilibrium by Theorem 3.23. If L is a cycle, (i) follows from Theorem 3.24. □

PROOF SKETCH OF THEOREM 3.24. That B is open is a consequence of the fact that $\gamma + K$ and $\gamma - K$ are closed. We show that $B \cap D$ is positively invariant. If $x \in B \cap D$, $y \in \gamma$ and $t > 0$ then $\Phi_{-t}(y) \in \gamma$ so x is not related to it. Since the forward flow of a competitive system preserves the property of being unrelated, $\Phi_t(x)$ is unrelated to y. Therefore, $\Phi_t(x) \in B \cap D$.

As in the proof of Theorem 3.17, for $v > 0$, H_v denotes the hyperplane orthogonal to v and Q the orthogonal projection onto H_v along v. Q is one-to-one on γ so $Q(\gamma)$ is a Jordan curve in H_v. Let H_{i} and H_{e} denote the interior and exterior components of $H_v \setminus Q(\gamma)$. If $x \in Q^{-1}(Q(\gamma))$ then $Q(x) = Q(y)$ for some $y \in \gamma$ and therefore either $x = y$, $x \ll y$ or $y \ll x$. In any case, $x \notin B$. Hence,

$$B = \big(B \cap Q^{-1}(H_{\mathrm{i}})\big) \cup \big(B \cap Q^{-1}(H_{\mathrm{e}})\big).$$

Set $B(\gamma) = B \cap Q^{-1}(H_{\mathrm{i}})$.

Given $z \in H_{\mathrm{i}}$, let $A_z^+ := \{s \in \mathbb{R}\colon z + sv \in \gamma + K\}$ and $A_z^- := \{s \in \mathbb{R}\colon z + sv \in \gamma - K\}$. A_z^+ clearly contains all large s by compactness of γ and it is closed because $\gamma + K$ is closed. If $s \in A_z^+$, there exists $y \in \gamma$ and $k \in K$ such that $z + sv = y + k$ so $z + (s+r)v = y + k + rv$, implying that $s + r \in A_z^+$ for all $r \geqslant 0$. It follows that $A_z^+ = [s_+(z), \infty)$, and similarly, $A_z^- = (-\infty, s_-(z)]$. If $s_-(z) \geqslant z_+(z)$ so $A_z^+ \cap A_z^-$ is nonempty, then there exists $s \in \mathbb{R}$, $k_i \in K$, and $y_i \in \gamma$ such that $z + sv = y_1 + k_1 = y_2 - k_2$. We must have $k_1 = k_2 = 0$ or else $y_2 > y_1$, a contradiction to Proposition 3.16, but then $z + sv = y_1$ so $z = Qy_1$ contradicting that $z \in H_{\mathrm{i}}$. We conclude that $s_-(z) < z_+(z)$ and that $z + sv \in B(\gamma)$ if and only if $s_-(z) < s < s_+(z)$. It follows that

$$B(\gamma) = \big\{z + sv\colon\ z \in H_{\mathrm{i}},\ s \in \big(s_-(z), s_+(z)\big)\big\}.$$

It is easy to show that the maps $z \mapsto s_{\pm}(z)$ are continuous and satisfy $s_+(z) - s_-(z) \to 0$ as $z \to y \in \gamma$ and this implies that $B(\gamma)$ is a 3-cell. See the argument given in Smith [187, 194].

To prove $B(\gamma) \subset [p, q]$, we identify K^* as the set of x such that $\langle x, k\rangle \geqslant 0$ for all $k \in K$ (where $\langle x, k\rangle$ denotes inner product). Schneider and Vidyasagar [177] proved the elegant result that every vector x has a unique representation

$$x = k - w, \quad k \in K,\ w \in K^*,\ \langle w, k\rangle = 0.$$

Choose any $z \in B \cap (\mathbb{R}^3 \setminus [p, q])$ and write

$$z - p = k - w, \quad k \in K, w \in K^*,\ \langle w, k\rangle = 0,$$

$$q - z = k' - w', \quad k' \in K, w' \in K^*,\ \langle w', k'\rangle = 0.$$

Observe that $w > 0$, $w' > 0$ because $z \in B$.

Either $k > 0$ or $k' > 0$. For if $k = k' = 0$ then $q - p = -(w + w')$, so

$$0 \leqslant \langle w + w', q - p\rangle = -\|w + w'\|^2 \leqslant 0.$$

This entails $w + w' = 0$ and thus $p = q$, a contradiction.

We assume $k > 0$, as the case $k' > 0$ is similar, and even follows formally by replacing K with $-K$. Then $w > 0$. Consider the ray $R = \{z + tk\colon\ t \geqslant 0\}$. If $y \in \gamma$, then

$$\langle w, z + tk - y\rangle = \langle w, z - p\rangle + \langle w, p - y\rangle \leqslant \langle w, z - p\rangle = -\|w\|^2 < 0.$$

Because z and u are unrelated, there exists $u \in K^*$ such that $\langle u, z - y\rangle > 0$. So

$$\langle u, z + tk - y\rangle = \langle u, z - y\rangle + t(z, k) \geqslant \langle u, z - y\rangle > 0.$$

This shows that no point of R is related to any point of γ. Therefore R and hence z are in the unbounded component of B.

As $B(\gamma)$ is a connected component of the positively invariant set B, it is positively invariant. Consequently its closure is a positively invariant set homeomorphic to the closed unit ball in $\mathbb{R}^3$. It therefore contains an equilibrium by a standard argument using the Brouwer Fixed Point Theorem (see, e.g., Hale [57, Theorem I.8.2]). □

If $B(\gamma)$ contains only nondegenerate equilibria $x_1, x_2, \ldots, x_m$, then standard topological degree arguments imply that m is odd and that $1 = \sum_{i=1}^{m} (-1)^{s_i}$ where $s_i \in \{0, 1, 2, 3\}$ is the number of positive eigenvalues of $Df(x_i)$. See Smith [187] for the proof and further information on equilibria in $B(\gamma)$.

There are many papers devoted to competitive Lotka–Volterra systems in $\mathbb{R}^3$, largely stimulated by the work of M. Zeeman. See for example [82,223,237,239,243,240,242] and references therein. The paper of Li and Muldowney [115] contains an especially nice application to epidemiology. Additional results for three-dimensional competitive and cooperative systems can be found in references [66,75–77,41,194,196,247,248].

The recent paper of Ortega and Sánchez [153] is noteworthy for employing a cone related to the ice-cream cone and observing that results for competitive systems are valid for general cones with nonempty interior. They show that if P is a symmetric matrix of dimension n having one positive eigenvalue λ_+ with corresponding unit eigenvector e_+, and $n-1$ negative eigenvalues, then (3.4) is monotone with respect to the order generated by the cone $K := \{x \in \mathbb{R}^n\colon\ \langle Px, x\rangle \geqslant 0,\ \langle x, e_+\rangle \geqslant 0\}$ if and only if there exists a function $\mu : \mathbb{R}^n \to \mathbb{R}$ such that the matrix $P \cdot Df_x + (Df_x)^T \cdot P + \mu(x)P$ is positive semidefinite for all x. They use this result to show that one of the results of R.A. Smith [204] on the existence of an orbitally stable periodic orbit, in the special case $n = 3$, follows from the results for competitive systems. It is not hard to see that if (3.4) satisfies the conditions above then after a change of variables in (3.4), the resulting system is monotone with respect to the standard ice-cream cone.

For applications of competitive and cooperative systems, see for example Benaïm [15], Benaïm and Hirsch [16,17], Hirsch [69,74] Hofbauer and Sandholm [81], Hsu and Waltman [84], Smith [194,196], Smith and Waltman [202].

4. Delay differential equations

4.1. *The semiflow*

The aim of the present section is to apply the theory developed in Sections 1 and 2 to differential equations containing delayed arguments. Such equations are often referred to as delay differential equations or functional differential equations. Since delay differential equations contain ordinary differential equations as a special case, when all delays are zero, the treatment is quite similar to the previous section. The main difference is that a delay differential equation generally can't be solved backward in time and therefore there is not a well-developed theory of competitive systems with delays.

Delay differential equations generate infinite-dimensional dynamical systems and there are several choices of state space. We restrict attention here to equations with bounded delays and follow the most well-developed theory (see Hale and Verduyn Lunel [61]). If r denotes the maximum delay appearing in the equation, then the space $\mathcal{C} := C([-r, 0], \mathbb{R}^n)$ is a natural choice of state space. Given a cone K in $\mathbb{R}^n$, $\mathcal{C}_K$ contains the cone of functions which map $[-r, 0]$ into K. The section begins by identifying sufficient conditions on the right hand side of the delay differential equation for the semiflow to be monotone with respect to the ordering induced by this cone. This quasimonotone condition reduces to the quasimonotone condition for ordinary differential equations when no delays are present. Our main goal is to identify sufficient conditions for a delay differential equation to generate an eventually strongly monotone semiflow so that results from Sections 1 and 2 may be applied.

In order to motivate fundamental well-posedness issues for delay equations, it is useful to start with a consideration of a classical example that has motivated much research in the field (see, e.g., Krisztin et al. [105] and Hale and Verduyn Lunel [61]), namely the equation

$$x'(t) = -x(t) + h\big(x(t-r)\big), \quad t \geqslant 0, \tag{4.1}$$

where h is continuous and $r > 0$ is the delay. It is clear that $x(t)$ must be prescribed on the interval $[-r, 0]$ in order that it be determined for $t \geqslant 0$. A natural space of initial conditions is the space of continuous functions on $[-r, 0]$, which we denote by $\mathcal{C}$, where $n = 1$ in this case. $\mathcal{C}$ is a Banach space with the usual uniform norm $|\phi| = \sup\{|\phi(\theta)|\colon -r \leqslant \theta \leqslant 0\}$. If $\phi \in \mathcal{C}$ is given, then it is easy to see that the equation has a unique solution $x(t)$ for $t \geqslant 0$ satisfying

$$x(\theta) = \phi(\theta), \quad -r \leqslant \theta \leqslant 0.$$

If the state space is $\mathcal{C}$, then we need to construct from the solution $x(t)$, an element of the space $\mathcal{C}$ to call the state of the system at time t. It should have the property that it uniquely determines $x(s)$ for $s \geqslant t$. The natural choice is $x_t \in \mathcal{C}$, defined by

$$x_t(\theta) = x(t+\theta), \quad -r \leqslant \theta \leqslant 0.$$

Then, $x_0 = \phi$ and $x_t(0) = x(t)$.

The general autonomous functional differential equation is given by

$$x'(t) = f(x_t), \tag{4.2}$$

where $f : D \to \mathbb{R}^n$, D is an open subset of $\mathcal{C}$ and f is continuous. In the example above, f is given by $f(\phi) = -\phi(0) + h(\phi(-r))$ for $\phi \in \mathcal{C}$. Observe that (4.2) includes the system of ordinary differential equations

$$x' = g(x),$$

where $g : \mathbb{R}^n \to \mathbb{R}^n$, as a special case. Simply let $f(\phi) = g(\phi(0))$ so that $f(x_t) = g(x_t(0)) = g(x(t))$.

It will always be assumed that (4.2), together with the initial condition $x_0 = \phi \in D$ has a unique, maximally defined solution, denoted by $x(t,\phi)$, on an interval $[0,\sigma)$. The state of the system is denoted by $x_t(\phi)$ to emphasize the dependence on the initial data. Uniqueness of solutions holds if, for example, f is Lipschitz on compact subsets of D (see Hale and Verduyn Lunel [61]). This holds, for example, if $f \in C^1(D)$ has locally bounded derivative. If uniqueness of solutions of initial value problems hold, then the map $(t,\phi) \to x_t(\phi)$ is continuous. Therefore, a (local) semiflow on D can be defined by

$$\Phi_t(\phi) = x_t(\phi). \tag{4.3}$$

In contrast to the case of ordinary differential equations, $x(t,\phi)$ cannot usually be defined for $t \leqslant 0$ as a solution of (4.2) and consequently, Φ_t need not be one-to-one.

It will be convenient to have notation for the natural embedding of $\mathbb{R}^n$ into $\mathcal{C}$. If $x \in \mathbb{R}^n$, let $\hat{x} \in \mathcal{C}$ be the constant function equal to x for all values of its argument. The set of equilibria for (4.2) is given by

$$E = \{\hat{x} \in D\colon\ x \in \mathbb{R}^n \text{ and } f(\hat{x}) = 0\}.$$

4.2. *The quasimonotone condition*

Given that $\mathcal{C}$ is a natural state space for (4.2), we now consider what sort of cones in $\mathcal{C}$ will yield useful order relations. The most natural such cones are those induced by cones in $\mathbb{R}^n$. Let K be a cone in $\mathbb{R}^n$ with nonempty interior and K^* denote the dual cone. All inequalities hereafter are assumed to be those induced on $\mathbb{R}^n$ by K. The cone K induces a cone $\mathcal{C}_K$ in the Banach space $\mathcal{C}$ defined by

$$\mathcal{C}_K = \{\phi \in \mathcal{C}\colon\ \phi(\theta) \geqslant 0,\ -r \leqslant \theta \leqslant 0\}.$$

It has nonempty interior in $\mathcal{C}$ given by $\operatorname{Int} \mathcal{C}_K = \{\phi \in \mathcal{C}_K\colon\ \phi(\theta) \gg 0, \theta \in [-r, 0]\}$. The usual notation $\leqslant, <, \ll$ will be used for the various order relations on $\mathcal{C}$ generated by $\mathcal{C}_K$. In particular, $\phi \leqslant \psi$ holds in $\mathcal{C}$ if and only if $\phi(s) \leqslant \psi(s)$ holds in $\mathbb{R}^n$ for every $s \in [-r, 0]$. The same notation will also be used for the various order relations on $\mathbb{R}^n$ but hopefully the context will alert the reader to the appropriate meaning. Cones in $\mathcal{C}$ that are not induced by a cone in $\mathbb{R}^n$ have also proved useful. See Smith and Thieme [198,200,194].

An immediate aim is to identify sufficient conditions on f for the semiflow Φ to be a monotone semiflow. The following condition should seem natural since it generalizes the condition (QM) for ordinary differential equations in the previous section. We refer to it here as the *quasimonotone condition*, (QMD) for short. “D” in the notation, standing for delay, is used so as not to confuse the reader with (QM) of the previous section. We follow this pattern in several definitions in this section.

(QMD) $\phi, \psi \in D, \phi \leqslant \psi$ and $\eta(\phi(0)) = \eta(\psi(0))$ for some $\eta \in K^*$, implies $\eta(f(\phi)) \leqslant \eta(f(\psi))$.

For the special case $K = \mathbb{R}^n_+$, (QMD) becomes:

$$\phi, \psi \in D,\ \phi \leqslant \psi \text{ and } \phi_i(0) = \psi_i(0) \quad \text{implies} \quad f_i(\phi) \leqslant f_i(\psi).$$

As in Section 3, it is convenient to consider the nonautonomous equation

$$x'(t) = f(t, x_t), \tag{4.4}$$

where $f : \Omega \to \mathbb{R}^n$ is continuous on Ω, an open subset of $\mathbb{R} \times \mathcal{C}$. Given $(t_0, \phi) \in \Omega$, we write $x(t, t_0, \phi, f)$ and $x_t(t_0, \phi, f)$ for the maximally defined solution and state of the system at time t satisfying $x_{t_0} = \phi$. We assume this solution is unique, which will be the case if f is Lipschitz in its second argument on each compact subset of Ω. We drop the last argument f from $x(t, t_0, \phi, f)$ when no confusion over which f is being considered will result.

$f : \Omega \to \mathbb{R}^n$ is said to satisfy (QMD) if $f(t, \cdot)$ satisfies (QMD) on $\Omega_t \equiv \{\phi \in \mathcal{C}\colon (t, \phi) \in \Omega\}$ for each t.

The next theorem not only establishes the desired monotonicity of the semiflow Φ but also allows comparisons of solutions between related functional differential equations. It generalizes Theorem 3.2 of Chapter 3 to functional differential equations and is a generalization of Proposition 1.1 of [190] and Theorem 5.1.1 of [194] where $K = \mathbb{R}^n_+$ is considered. The quasimonotone condition for delay differential equations seems first to have appeared in the work of Kunisch and Schappacher [109], Martin [128], and Ohta [152].

THEOREM 4.1. *Let $f, g : \Omega \to \mathbb{R}^n$ be continuous, Lipschitz on each compact subset of Ω, and assume that either f or g satisfies* (QMD). *Assume also that $f(t, \phi) \leqslant g(t, \phi)$ for all $(t, \phi) \in \Omega$. Then*

$$\phi, \psi \in \Omega_{t_0},\ \phi \leqslant \psi,\ t \geqslant t_0, \quad \Longrightarrow \quad x(t, t_0, \phi, f) \leqslant x(t, t_0, \psi, g)$$

for all t for which both are defined.

PROOF. Assume that f satisfies (QMD), a similar argument holds if g satisfies (QMD). Let $e \in \mathbb{R}^n$ satisfy $e \gg 0$, $g_\epsilon(t, \phi) := g(t, \phi) + \epsilon e$ and $\psi_\epsilon := \psi + \epsilon \hat{e}$, for $\epsilon \geqslant 0$. If $x(t, t_0, \psi, g)$ is defined on $[t_0 - r, t_1]$ for some $t_1 > t_0$, then $x(t, t_0, \psi_\epsilon, g_\epsilon)$ is also defined on this same interval for all sufficiently small positive ϵ and

$$x(t, t_0, \psi_\epsilon, g_\epsilon) \to x(t, t_0, \psi, g), \quad \epsilon \to 0,$$

for $t \in [t_0, t_1]$ by Hale and Verduyn Lunel [61, Theorem 2.2.2]. We will show that $x(t, t_0, \phi, f) \ll x(t, t_0, \psi_\epsilon, g_\epsilon)$ on $[t_0 - r, t_1]$ for small positive ϵ. The result will then follow by letting $\epsilon \to 0$. If the assertion above were false for some ϵ, then applying the remark below Proposition 3.1, there exists $s \in (t_0, t_1]$ such that $x(t, t_0, \phi, f) \ll x(t, t_0, \psi_\epsilon, g_\epsilon)$ for $t_0 \leqslant t < s$ and $\eta(x(s, t_0, \phi, f)) = \eta(x(s, t_0, \psi_\epsilon, g_\epsilon))$ for some nontrivial $\eta \in K^*$. As $\eta(x(t, t_0, \phi, f)) < \eta(x(t, t_0, \psi_\epsilon, g_\epsilon))$ for $t_0 \leqslant t < s$, by Proposition 3.1, we conclude that $\frac{\mathrm{d}}{\mathrm{d}t}|_{t=s}\eta(x(s, t_0, \phi, f)) \geqslant \frac{\mathrm{d}}{\mathrm{d}t}|_{t=s}\eta(x(s, t_0, \psi_\epsilon, g_\epsilon))$. But

$$\begin{aligned}
\left.\frac{\mathrm{d}}{\mathrm{d}t}\right|_{t=s} \eta\big(x(s, t_0, \psi_\epsilon, g_\epsilon)\big) &= \eta\big(g\big(s, x_s(t_0, \psi_\epsilon, g_\epsilon)\big)\big) + \epsilon\eta(e) \\
&> \eta\big(f\big(s, x_s(t_0, \psi_\epsilon, g_\epsilon)\big)\big) \\
&\geqslant \eta\big(f\big(s, x_s(t_0, \phi, f)\big)\big) \\
&= \left.\frac{\mathrm{d}}{\mathrm{d}t}\right|_{t=s} \eta\big(x(s, t_0, \phi, f)\big),
\end{aligned}$$

where the last inequality follows from (QMD). This contradiction implies that no such s can exist, proving the assertion. □

In the case of the autonomous system (4.2), taking $f = g$ in Theorem 1.1 implies that $x_t(\phi) \leqslant x_t(\psi)$ for $t \geqslant 0$ such that both solutions are defined. In other words, the semiflow Φ defined by (4.3) is monotone. In contrast to Theorem 3.2 of the previous section, if $\phi < \psi$ we cannot conclude that $x(t,\phi) < x(t,\psi)$ or $x_t(\phi) < x_t(\psi)$ since Φ_t is not generally one-to-one. A simple example is provided by the scalar equation (4.2) with $r = 1$ and $f(\phi) := \max \phi$, which satisfies (QMD). Let $\phi < \psi$ be strictly increasing on $[-1,-1/2]$, $\phi(-1) = \psi(-1) = 0$, $\phi(-1/2) = \psi(-1/2) = 1$, and $\phi(\theta) = \psi(\theta) = -2\theta$ for $-1/2 < \theta \leqslant 0$. It is easy to see that $x(t,\phi) = x(t,\psi)$ for $t \geqslant 0$.

It is useful to have sufficient conditions for the positive invariance of K. By this we mean that $t_0 \in J$ and $\phi \geqslant 0$ implies $x(t,t_0,\phi) \geqslant 0$ for all $t \geqslant t_0$ for which it is defined. The following result provides the expected necessary and sufficient condition. The proof is similar to that of Theorem 4.1; the result is the delay analog of Proposition 3.3.

THEOREM 4.2. *Assume that $J \times K \subset \Omega$ where J is an open interval. Then K is positively invariant for* (4.4) *if and only if for all $t \in J$*

(PD) $\phi \geqslant 0$, $\lambda \in K^*$ *and* $\lambda(\phi(0)) = 0$ *implies* $\lambda(f(t,\phi)) \geqslant 0$

holds.

Let $L: J \to L(\mathcal{C},\mathbb{R}^n)$ be continuous, where $L(\mathcal{C},\mathbb{R}^n)$ denotes the space of bounded linear operators from $\mathcal{C}$ to $\mathbb{R}^n$, and consider the initial value problem for the linear nonautonomous functional differential equation

$$x' = L(t)x_t, \quad x_{t_0} = \phi. \tag{4.5}$$

Observing that (PD) and (QMD) are equivalent for linear systems, we have the following corollary.

COROLLARY 4.3. *Let $x(t,t_0,\phi)$ be the solution of* (4.5). *Then $x(t,t_0,\phi) \geqslant 0$ for all $t \geqslant t_0$ and all $\phi \geqslant 0$ if and only if for each $t \in J$,* (PD) *holds for $L(t)$.*

As in the case of ordinary differential equations, a stronger condition than (PD) for linear systems is that for every $t \in J$, there exists $\alpha \in \mathbb{R}$ such that $L(t)\phi + \alpha\phi(0) \geqslant 0$ whenever $\phi \geqslant 0$.

It is useful to invoke the Riesz Representation Theorem [171] in order to identify $L(t)$ with a matrix of signed Borel measures $\eta(t) = (\eta(t)_{ij})$:

$$L(t)\phi = \int_{-r}^{0} \mathrm{d}\eta(t)\phi. \tag{4.6}$$

The Radon–Nikodym decomposition of η_{ij} with respect to the Dirac measure δ with unit mass at 0 gives $\eta_{ij}(t) = a_{ij}(t)\delta + \tilde{\eta}_{ij}(t)$ where a_{ij} is a scalar and $\tilde{\eta}_{ij}(t)$ is mutually singular with respect to δ. In particular, the latter assigns zero mass to $\{0\}$. Therefore,

$$L(t)\phi = A(t)\phi(0) + \tilde{L}(t)\phi, \quad \tilde{L}(t)\phi := \int_{-r}^{0} \mathrm{d}\tilde{\eta}(t)\phi. \tag{4.7}$$

Continuity of the map $t \to A(t)$ follows from continuity of $t \to L(t)$. The decomposition (4.7) leads to sharp conditions for (PD) to hold for $L(t)$.

PROPOSITION 4.4. (PD) *holds for* $L(t)$ *if and only if*

(a) $A(t)$ *satisfies* (P) *of Proposition* 3.3, *and*

(b) $\tilde{L}(t)\phi \geqslant 0$ *whenever* $\phi \geqslant 0$.

PROOF. If (a) and (b) hold, $\phi \geqslant 0$, $\lambda \in K^*$ and $\lambda(\phi(0)) = 0$ then $\lambda(L(t)\phi) = \lambda(A(t)\phi(0)) + \lambda(\tilde{L}(t)\phi) \geqslant 0$ because each summand on the right is nonnegative.

Conversely, if (PD) holds for $L(t)$, $v \in \partial K$, $\lambda \in K^*$, and $\lambda(v) = 0$, define $\phi_n(\theta) = \mathrm{e}^{n\theta} v$ on $[-r, 0]$. Then $\phi_n \geqslant 0$ and ϕ_n converges point-wise to zero, almost everywhere with respect to $\tilde{\eta}(t)$. By (PD),

$$\lambda(L(t)\phi_n) = \lambda(A(t)v + \tilde{L}(t)\phi_n) \geqslant 0.$$

Letting $n \to \infty$, we get $\lambda(A(t)v) \geqslant 0$ implying that (P) holds for $A(t)$. Let $\phi \geqslant 0$ be given and define $\phi_n(\theta) = [1 - \mathrm{e}^{n\theta}]\phi(\theta)$ on $[-r, 0]$, $n \geqslant 1$. ϕ_n converges point-wise to $\phi\chi$, where χ is the indicator function of the set $[-r, 0)$, and $\phi\chi = \phi$ almost everywhere with respect to $\tilde{\eta}(t)$. If $\lambda \in K^*$, then $\lambda(\phi_n(0)) = 0$ so applying (PD) we get $0 \leqslant \lambda(L(t)\phi_n) = \tilde{L}(t)\phi_n$. Letting $n \to \infty$ we get (b). □

For the remainder of this section, we suppose that $\Omega = J \times D$ where J is a nonempty open interval and $D \subset \mathcal{C}$ is open. Suppose that $\frac{\partial f}{\partial \phi}(t, \psi)$ exists and is continuous on $J \times D$ to $L(\mathcal{C}, \mathbb{R}^n)$. In that case, $x(t, t_0, \phi)$ is continuously differentiable in its last argument and $y(t, t_0, \chi) = \frac{\partial x}{\partial \phi}(t, t_0, \phi)\chi$ satisfies the variational equation

$$y'(t) = \frac{\partial f}{\partial \phi}\bigl(t, x_t(t, \phi)\bigr)y_t, \quad y_{t_0} = \chi. \tag{4.8}$$

See Theorem 2.4.1 of Hale and Verduyn Lunel [61]. We say that f (or (4.4)) is *K-co-operative* if for all $(t, \chi) \in J \times D$ the function $\psi \to \frac{\partial f}{\partial \phi}(t, \chi)\psi$ satisfies (PD). By Corollary 4.3 applied to the variational equation we have the following analog of Theorem 3.5 for functional differential equations. The proof is essentially the same.

THEOREM 4.5. *Let* $\frac{\partial f}{\partial \phi}(t, \psi)$ *exist and be continuous on* $J \times D$. *If* (QMD) *holds for* (4.4), *then* f *is* K*-cooperative. Conversely, if* D *is p-convex and* f *is* K*-cooperative, then* (QMD) *holds for* f.

Consider the nonlinear system

$$x'(t) = g\bigl(x(t), x(t - r_1), x(t - r_2), \ldots, x(t - r_m)\bigr), \tag{4.9}$$

where $g(x, y^1, y^2, \ldots, y^m)$ is continuously differentiable on $\mathbb{R}^{(m+1)n}$ and $r_{j+1} > r_j > 0$. Then

$$\frac{\partial f}{\partial \phi}(\psi) = \frac{\partial g}{\partial x}(x, Y)\delta + \sum_k \frac{\partial g}{\partial y^k}(x, Y)\delta_{-r_k}, \tag{4.10}$$

where δ_{-r_k} is the Dirac measure with unit mass at $\{-r_k\}$ and $x = \psi(0)$, $y^k = \psi(-r_k)$ and $(x, Y) := (x, y^1, y^2, \ldots, y^m)$. By Theorem 4.5, Corollary 4.3, and Proposition 4.4, (QMD) holds if and only if for each (x, Y), $\frac{\partial g}{\partial x}(x, Y)$ satisfies condition (P) and $\frac{\partial g}{\partial y^k}(x, Y)$ is K-positive. If $K = \mathbb{R}^n_+$, the condition becomes $\frac{\partial g_i}{\partial x_j}(x, Y) \geqslant 0$, for $i \neq j$ and $\frac{\partial g_i}{\partial y^k_j}(x, Y) \geqslant 0$ for all i, j, k; if, in addition, $n = 1$ then $\frac{\partial g}{\partial y^k}(x, Y) \geqslant 0$ for all k suffices.

4.3. *Eventual strong monotonicity*

We begin by considering the linear system (4.5). The following hypothesis for the continuous map $L : J \to L(\mathcal{C}, \mathbb{R}^n)$ reduces to (ST) of the previous section when $r = 0$:

(STD) for all $t \in J$ and $\phi \geqslant 0$ with $\phi(0) \in \partial K$ satisfying one of the conditions
(a) $\phi(-r) > 0$ and $\phi(0) = 0$, or
(b) $\phi(s) > 0$ for $-r \leqslant s \leqslant 0$,
there exists $\nu \in K^*$ such that $\nu(\phi(0)) = 0$ and $\nu(L(t)\phi) > 0$.

The following result is the analog of Theorem 3.6 of the previous section for delay differential equations.

THEOREM 4.6. *Let linear system* (4.5) *satisfy* (PD) *and* (STD) *and let $t_0 \in J$. Then*

$$\phi > 0,\ t \geqslant t_0 + 2r \quad \Longrightarrow \quad x(t, t_0, \phi) \gg 0.$$

In particular, $x_t(t_0, \phi) \gg 0$ for $t \geqslant t_0 + 3r$.

PROOF. By Corollary 4.3, we have that $x(t) := x(t, t_0, \phi) \geqslant 0$ for all $t \geqslant t_0$ that belong to J. There exists $t_1 \in (t_0, t_0 + r)$ such that $x(t_1 - r) = \phi(t_1 - r) = x_{t_1}(-r) > 0$ since $\phi > 0$. If $x(t_1) = 0$, then (STD)(a) implies the existence of $\nu \in K^*$ such that $\nu(L(t_1)x_{t_1}) > 0$. As $\nu(x(t)) \geqslant 0$ for $t \geqslant t_0$ and $\nu(x(t_1)) = 0$ we conclude that $\frac{\mathrm{d}}{\mathrm{d}t}|_{t=t_1}\nu(x(t)) \leqslant 0$. But $\frac{\mathrm{d}}{\mathrm{d}t}|_{t=t_1}\nu(x(t)) = \nu(L(t_1)x_{t_1}) > 0$, a contradiction. Therefore, $x(t_1) > 0$.

Now, by (4.7)

$$x' = A(t)x + \tilde{L}(t)x_t$$

from which we conclude

$$x(t) = X(t, t_1)x(t_1) + \int_{t_1}^{t} X(t, r)\tilde{L}(r)x_r \,\mathrm{d}r,$$

where $X(t, t_0)$ is the fundamental matrix for $y' = A(t)y$ satisfying $X(t_0, t_0) = I$. From (a) of Proposition 4.4 and Corollary 3.4, it follows that $X(t, t_0)$ is K positive for $t \geqslant t_0$. This, the fact that $x_r \geqslant 0$, and (b) of Proposition 4.4 imply that the integral belongs to K so we conclude that

$$x(t) \geqslant X(t, t_1)x(t_1) > 0, \quad t \geqslant t_1.$$

We claim that $x(t) \gg 0$ for $t \geqslant t_1 + r$. If not, there is a $t_2 \geqslant t_1 + r$ such that $x(t_2) = x_{t_2}(0) \in \partial K$ but $x_{t_2}(s) > 0$ for $-r \leqslant s \leqslant 0$. Then (STD) implies the existence of $\nu \in K^*$ such that $\nu(x(t_2)) = 0$ and $\nu(L(t_2)x_{t_2}) > 0$. Since $\nu(x(t)) \geqslant 0$ for $t \geqslant t_0$ we must have $\frac{\mathrm{d}}{\mathrm{d}t}|_{t=t_2}\nu(x(t)) \leqslant 0$. But $\frac{\mathrm{d}}{\mathrm{d}t}|_{t=t_2}\nu(x(t)) = \nu(L(t_2)x_{t_2}) > 0$, a contradiction. We conclude that $x(t) \gg 0$ for $t \geqslant t_1 + r$. □

In a sense, (STD)(a) says that r has been correctly chosen; (STD)(b) is more fundamental. The next result gives sufficient conditions for it to hold.

PROPOSITION 4.7. *If $L(t)$ satisfies* (PD) *and either*
(a) *$A(t)$ satisfies* (ST), *or*
(b) $\phi > 0 \Longrightarrow \tilde{L}(t)\phi \gg 0$
then (STD)(b) *holds.*

PROOF. This is immediate from the definitions, the decomposition (4.7), Proposition 4.4, and the expression $\nu(L(t)\phi) = \nu(A(t)\phi(0)) + \nu(\tilde{L}(t)\phi)$. □

Theorem 4.6 leads immediately to a result on eventual strong monotonicity for the nonlinear system (4.4) where we assume that $\Omega = J \times D$ as above.

THEOREM 4.8. *Let D be p-convex, $\frac{\partial f}{\partial \phi}(t, \psi)$ exist and be continuous on $J \times D$ to $L(\mathcal{C}, \mathbb{R}^n)$, and f be K-cooperative. Suppose that* (STD) *holds for $\frac{\partial f}{\partial \phi}(t, \psi)$, for each $(t, \psi) \in J \times D$. Then*

$$\phi_0, \phi_1 \in D,\ \phi_0 < \phi_1 \quad \Longrightarrow \quad x(t, t_0, \phi_0) \ll x(t, t_0, \phi_1)$$

for all $t \geqslant t_0 + 2r$ for which both solutions are defined.

PROOF. By Theorem 4.5, we have $x(t, t_0, \phi_0) \leqslant x(t, t_0, \phi_1)$ for $t \geqslant t_0$ for which both solutions are defined. We apply the formula

$$x(t, t_0, \phi_1) - x(t, t_0, \phi_0) = \int_0^1 \frac{\partial x}{\partial \phi}\big(t, t_0, s\phi_1 + (1 - s)\phi_0\big)(\phi_1 - \phi_0)\,\mathrm{d}s.$$

Here, for $\psi \in D$ and $\beta \in \mathcal{C}$, $y(t, t_0, \beta) := \frac{\partial x}{\partial \phi}(t, t_0, \psi)\beta$ satisfies the variational equation (4.5) where $\phi = \beta$ and $L(t) = \frac{\partial f}{\partial \phi}(t, x_t(t_0, \psi))$. See Theorem 2.4.1 of Hale and Verduyn Lunel [61]. The desired conclusion will follow if we show that $y(t, t_0, \beta) \gg 0$ for

$t \geqslant t_0 + 2r$ for $\psi = s\phi_1 + (1-s)\phi_0$ and $\beta = \phi_1 - \phi_0 > 0$. By Theorem 4.6, it suffices to show that $L(t)$ satisfies (PD) and (STD). But this follows from our hypotheses. □

In the next result, Theorem 4.8 is applied to system (4.9). We make use of notation introduced below Theorem 4.5.

COROLLARY 4.9. *Let* $g : \mathbb{R}^{(m+1)n} \to \mathbb{R}^n$ *be continuously differentiable and satisfy*

(a) $\frac{\partial g}{\partial x}(x, Y)$ *satisfies* (P) *for each* $(x, Y) \in Z$;

(b) *for each* k, $\frac{\partial g}{\partial y^k}(x, Y)$ *is* K *positive*;

(c) *either* $\frac{\partial g}{\partial x}(x, Y)$ *satisfies* (ST) *or some* $\frac{\partial g}{\partial y^k}(x, Y)$ *is strongly positive on* K.

Then the hypotheses of Theorem 4.8 *hold for* (4.9).

PROOF. Recalling (4.10), it is evident that (a) and (b) imply that (4.9) is K-cooperative. Hypothesis (c) and Proposition 4.7 imply that (STD) holds. □

In the special case that (4.9) is a scalar equation, $m = 1$ and $K = \mathbb{R}_+$, then $\frac{\partial g}{\partial y}(x, y) > 0$ suffices to ensure an eventually strongly monotone semiflow.

4.4. *K is an orthant*

Our results can be improved in the case that K is a product cone such as $\mathbb{R}^n_+ = \prod_{i=1}^n \mathbb{R}_+$, i.e., an orthant. The following example illustrates the difficulty with our present set up.

$$x_1'(t) = -x_1(t) + x_2(t - 1/2),$$
$$x_2'(t) = x_1(t-1) - x_2(t).$$

Observe that (PD) holds for the standard cone. For initial data, take $\phi = (\phi_1, \phi_2) \in \mathcal{C}$ $(r = 1)$ where $\phi_1 = 0$ and $\phi_2(\theta) > 0$ for $\theta \in (-1, -2/3)$ and $\phi_2(\theta) = 0$ elsewhere in $[-1, 0]$. The initial value problem can be readily integrated by the method of steps of length $1/2$ and one sees that $x(t) = 0$ for all $t \geqslant -2/3$. In the language of semiflows, $\phi > 0$ yet $\Phi_t(\phi) = \Phi_t(0) = 0$ for all $t \geqslant 0$. The problem is that $C([-1, 0], \mathbb{R}^2)$ is not the optimal state space; a better one is the product space $X = C([-1, 0], \mathbb{R}) \times C([-1/2, 0], \mathbb{R})$. Obviously, an arbitrary cone in $\mathbb{R}^2$ will not induce a cone in the product space X.

For the remainder of this section we focus on the standard cone but the reader should observe that an analogous construction works for any orthant $K = \{x\colon\ (-1)^{m_i} x_i \geqslant 0\}$. Motivated by the example in the previous paragraph, let $r = (r_1, r_2, \ldots, r_n) \in \mathbb{R}^n_+$ be a vector of delays, $R = \max r_i$ and define

$$\mathcal{C}_r = \prod_{i=1}^n C\big([-r_i, 0], \mathbb{R}\big).$$

Note that we allow some delays to be zero. We write $\phi = (\phi_1, \phi_2, \ldots, \phi_n)$ for a generic point of $\mathcal{C}_r$. $\mathcal{C}_r$ is a Banach space with the norm $|\phi| = \sum |\phi_i|$. Let

$$\mathcal{C}_r^+ = \prod_{i=1}^n C\big([-r_i, 0], \mathbb{R}_+\big)$$

denote the cone of functions in $\mathcal{C}_r$ with nonnegative components. It has nonempty interior given by those functions with strictly positive components. As usual, we use the notation $\leqslant, <, \ll$ for the corresponding order relations on $\mathcal{C}_r$ induced by $\mathcal{C}_r^+$. If $x_i(t)$ is defined on $[-r_i, \sigma)$, $1 \leqslant i \leqslant n$, $\sigma > 0$ then we may redefine $x_t \in \mathcal{C}_r$ as $x_t = (x_t^1, x_t^2, \ldots, x_t^n)$ where $x_t^i(\theta) = x_i(t + \theta)$ for $\theta \in [-r_i, 0]$. Notice that now, the subscript signifying a particular component will be raised to a superscript when using the subscript "t" to denote a function.

If $D \subset \mathcal{C}_r$ is open, J is an open interval and $f : J \times D \to \mathbb{R}^n$ is given, then the standard existence and uniqueness theory for the initial value problem associated with (4.4) is unchanged. Furthermore, Theorems 4.1 and 4.2, and Corollary 4.3 remain valid in our current setting where, of course, we need only make use of the coordinate maps $\eta(x) = x_i$, $1 \leqslant i \leqslant n$ in (QMD) and (PD). Our goal now is to modify (STD) so that we may obtain a result like Theorem 4.6 that applies to systems such as the example above. We begin by considering the linear system (4.5) where $L : J \to L(\mathcal{C}_r, \mathbb{R}^n)$ is continuous and let $L_i(t)\phi := \langle e_i, L(t)\phi\rangle$, $1 \leqslant i \leqslant n$.

In our setting, $L(t)$ satisfies (PD) if and only if:

$$\phi \geqslant 0 \text{ and } \phi_i(0) = 0 \quad \text{implies} \quad L_i(t)\phi \geqslant 0.$$

THEOREM 4.10. *Let linear system* (4.5) *satisfy* (PD) *and*

(i) $t \in J, r_j > 0, \phi \geqslant 0, \phi_j(-r_j) > 0 \Longrightarrow L_i(t)\phi > 0$ *for some* i;

(ii) *for every proper subset* I *of* $N := \{1, 2, \ldots, n\}$, *there exists* $j \in N \setminus I$ *such that* $L_j(t)\phi > 0$ *whenever* $\phi \geqslant 0$, $\phi_i(s) > 0$, $-r_i \leqslant s \leqslant 0$, $i \in I$.

Then $x(t, \phi, t_0) \gg 0$ *if* $\phi > 0$ *for all* $t \geqslant t_0 + nR$.

PROOF. By (PD) and Corollary 4.3 we have $x(t) \geqslant 0$ for $t \geqslant t_0$. An application of the Riesz Representation Theorem and Radon–Nikodym Theorem implies that for $i = 1, 2, \ldots, n$, we have

$$L_i(t)\phi = a_i(t)\phi_i(0) + \sum_{j=1}^n \int_{-r_j}^0 \phi_j(\theta)\, \mathrm{d}_\theta \eta_{ij}(t, \theta) = a_i(t)\phi_i(0) + \bar{L}_i(t)\phi,$$

where $\eta_{ij}(t)$ is a positive Borel measure on $[-r_j, 0]$, $a_i(t) \in \mathbb{R}$ and $\bar{L}_i(t)\phi \geqslant 0$ whenever $\phi \geqslant 0$. Moreover, $t \to \eta_{ij}(t)$ and $t \to a_i(t)$ are continuous. See Smith [190,194] for details. The representation of L_i in terms of signed measures, $\bar{\eta}_{ij}$, is standard; (PD) implies that $\eta_{ij} := \bar{\eta}_{ij}$ must be positive for $i \neq j$ and that $\bar{\eta}_{ii}$ has the Lebesgue decomposition $\bar{\eta}_{ii} = a_i\delta + \eta_{ii}$ with respect to δ, the Dirac measure of unit mass at zero, and η_{ii} is a positive measure which is mutually singular with respect to δ.

If $x_i(t_1) > 0$ for some i and $t_1 > t_0$ then from $x_i'(t) = a_i(t)x_i(t) + \bar{L}_i(t)x_t \geqslant a_i(t)x_i(t)$ we conclude from standard differential inequality arguments that $x_i(t) > 0$ for $t \geqslant t_1$.

As $\phi > 0$, there exists j such that $\phi_j > 0$. If $r_j = 0$ then $x_j(t_0) > 0$; if $r_j > 0$ then $x_j(t_1 - r_j) > 0$ for some $t_1 \in (t_0, t_0 + r_j)$. In this case, it follows from (i) that $x_i'(t_1) = L_i(t_1)\phi > 0$ for some i and hence $x_i(t_1) > 0$. Hence, $x_i(t) > 0$ for $t \geqslant t_1$ by the previous paragraph. Applying (ii) with $I = \{i\}$ and $t = t_2 = t_1 + r_i$ we may find $k \neq i$ such that $x_k'(t_2) = L_k(t_2)x_{t_2} > 0$ because $x_{t_2}^i(s) > 0$, $-r_i \leqslant s \leqslant 0$. Therefore, we must have $x_k(t_2) > 0$ and hence $x_k(t) > 0$ for $t \geqslant t_2$. Obviously, we may continue in this manner until we have all components positive for $t \geqslant t_0 + nR$ as asserted. □

Theorem 4.10 leads directly to a strong monotonicity result for the nonlinear nonautonomous delay differential equation (4.4) in the usual way. We extend the definition of K-cooperativity of f to our present setup with state space $\mathcal{C}_r$ exactly as before.

THEOREM 4.11. *Let $D \subset \mathcal{C}_r$ be p-convex, $\frac{\partial f}{\partial \phi}(t, \psi)$ exist and be continuous on $J \times D$ to $L(\mathcal{C}_r, \mathbb{R}^n)$, and f be K-cooperative. Suppose that for all $(t, \psi) \in J \times D$, $L(t) := \frac{\partial f}{\partial \phi}(t, \psi)$ satisfies the conditions of Theorem* 4.10. *Then*

$$\phi_0, \phi_1 \in D,\ \phi_0 < \phi_1,\ t \geqslant t_0 + nR \quad \Longrightarrow \quad x(t, t_0, \phi_0) \ll x(t, t_0, \phi_1).$$

The biochemical control circuit with delays, modeled by the system

$$\begin{aligned} x_1'(t) &= g\big(x_n(t - r_n)\big) - \alpha_1 x_1(t), \\ x_j'(t) &= x_{j-1}(t - r_{j-1}) - \alpha_j x_j(t), \quad 2 \leqslant j \leqslant n \end{aligned} \tag{4.11}$$

with decay rates $\alpha_j > 0$ and delays $r_i \geqslant 0$ with $R > 0$ provides a good application of Theorem 4.11 which cannot be obtained by Theorem 4.8 if the delays are distinct. We assume the $g : \mathbb{R}_+ \to \mathbb{R}_+$ is continuously differentiable and $g' > 0$. Equation (4.11) is an autonomous system for which $\mathcal{C}_r^+$ is positively invariant by Theorem 4.2. See Smith [191, 194] for more on this application.

4.5. *Generic convergence for delay differential equations*

The aim of this section is to apply Theorem 4.8 and Theorem 4.11 to the autonomous delay differential equation (4.2) to conclude that the generic solution converges to equilibrium. To Φ, defined by (4.3), we associate C, S and E, denoting respectively the sets of convergent, stable and equilibrium points. The main result of this section is the following.

THEOREM 4.12. *Let $f \in C^1(D)$,* (4.2) *be cooperative on the p-convex open subset D of $\mathcal{C}$ or $\mathcal{C}_r$ and satisfy*:

(a) *The hypotheses of Theorem* 4.8 *or of Theorem* 4.11 *hold*;

(b) *Every positive semiorbit of Φ has compact closure in D and $D = AC \cup BC$.*

Then

(i) *$C \cap S$ contains a dense open subset of D, consisting of points whose trajectories converge to equilibria*;

(ii) *If E is compact there is a stable equilibrium, and an asymptotically stable equilibrium when E is finite.*

PROOF. For definiteness, suppose that (4.2) is cooperative on the p-convex open subset D of $\mathcal{C}$ and that the hypotheses of Theorem 4.8 hold. The other case is proved similarly. Assumption (a) ensures that Φ is eventually strongly monotone. Moreover, the derivative of $\Phi_t(\phi)$ with respect to ϕ exists and $\Phi'_\tau(\phi)\chi = y_\tau(t_0, \chi)$, where $y(t, t_0, \chi)$ is the solution of the variational equation (4.8). As our hypotheses ensure that $L(t) = \frac{\partial f}{\partial \phi}(x_t(\phi))$ satisfies (STD), we conclude from Theorem 4.6 that $\Phi'_\tau(\phi)$ is strongly positive for $\tau \geqslant 3r$. Compactness of $\Phi'_\tau(\phi) : \mathcal{C} \to \mathcal{C}$ for $\tau \geqslant r$ follows from the fact that a bound for $y_\tau(t_0, \chi)$, uniform for χ belonging to a bounded set $B \subset \mathcal{C}$, can be readily obtained so, using (4.8), we may also find a uniform bound for $y'(t, t_0, \chi)$, $\tau - r \leqslant t \leqslant \tau$. See, e.g., Hale [58, Theorem 4.1.1] for more detail.

The hypotheses of Theorem 2.26, with $X = D$, are fulfilled: D is normally ordered and $D = BC \cup AC$; while (M) and (D^*) hold as noted above. Therefore Theorem 2.26 implies the conclusion. □

In the special case that (4.2) is scalar ($n = 1$) we note that the set E of equilibria is totally ordered in $\mathcal{C}_r$ or $\mathcal{C}$ so the set of quasiconvergent points coincides with the set of convergent points: $Q = C$. The classical scalar delay differential equation (4.1) has been thoroughly investigated in the case of monotone delayed feedback ($f(0) = 0$ and $f' > 0$) by Krisztin et al. [105]. They characterize the closure of the unstable manifold of the trivial solution in case it is three-dimensional and determine in remarkable detail the dynamics on this invariant set.

Smith and Thieme [198,200,194] introduce an exponential ordering, not induced by a cone in $\mathbb{R}^n$, that extends the scope of application of the theory described here. One of the salient results from this work is that a scalar delay equation for which the product of the delay r and the Lipschitz constant of f is smaller than e^{-1} generates an eventually strongly monotone semiflow with respect to the exponential ordering and therefore the generic orbit converges to equilibrium: the dynamics mimics that of the associated ordinary differential equation obtained by ignoring the delay. See also work of Pituk [159].

We have considered only bounded delays. Systems of delay differential equations with unbounded and even infinite delay are also of interest. See Wu [234] for extensions to such systems. Wu and Freedman [235] and Krisztin and Wu [106–108] extend the theory to delay differential equations of neutral type.

5. Monotone maps

5.1. *Background and motivating examples*

One of the chief motivations for the study of monotone maps is their importance in the study of periodic solutions to periodic quasimonotone systems of ordinary differential equations. See for example the monograph of Krasnosel'skii [99], the much cited paper of de Mottoni and Schiaffino [42], Hale and Somolinos [60], Smith [188,189], Liang and Jiang [121], and Wang and Jiang [229–231]. To fix ideas, let $f : \mathbb{R} \times \mathbb{R}^n \to \mathbb{R}^n$ be a locally Lipschitz function and consider the ordinary differential equation

$$x' = f(t, x). \tag{5.1}$$

As usual, denote by $x(t, t_0, x_0)$ the noncontinuable solution of the initial value problem $x(t_0) = x_0$, which for simplicity we assumed is defined for all t. If f is periodic in t of period one: $f(t + 1, x) = f(t, x)$ for all (t, x), then it is natural to consider the *period map* $T : \mathbb{R}^n \to \mathbb{R}^n$ defined by

$$T(x_0) = x(1, 0, x_0). \tag{5.2}$$

Its fixed points (periodic points) are in one-to-one correspondence with the periodic (subharmonic) solutions of (5.1). If K is a cone in $\mathbb{R}^n$ for which f satisfies the quasimonotone condition (QM), then it follows from Theorem 3.2 that T is a monotone map: $x \leqslant y$ implies $Tx \leqslant Ty$. Moreover, T has the important property, not shared with general monotone maps, that it is an orientation-preserving homeomorphism.

In a similar way, periodic solutions for second order parabolic partial differential equations with time-periodic data can be analyzed by considering period maps in appropriate function spaces. Here monotonicity comes from classical maximum principles. Hess [63] remains an up-to-date survey. See also Alikakos et al. [3] and Zhao [245]. Remarkable results are known for equations on a compact interval with standard boundary conditions. Chen and Matano [23] show that every forward (backward) bounded solution is asymptotic to a periodic solution; Brunovsky et al. [22] extend the result to more general equations. Chen et al. [24] give conditions for the period map to generate Morse–Smale dynamics and thus be structurally stable. Although monotonicity of the period map is an important consideration in these results, it is not the key tool. The fact that the number of zeros on the spatial interval of a solution of the linearized equation is non-increasing in time is far more important. See Hale [59] for a nice survey.

A different theme in order-preserving dynamics originates in the venerable subject of nonlinear elliptic and parabolic boundary value problems. The 1931 edition of Courant and Hilbert's famous book [34] refers to a paper of Bieberbach in *Göttingen Nachrichten*, 1912 dealing with the elliptic boundary value problem $\Delta u = \mathrm{e}^u$ in Ω, $u|\partial\Omega = f$, in a planar region Ω. A solution is found by iterating a monotone map in a function space. Courant and Hilbert extended this method to a broad class of such problems. Out of this technique grew the method of "upper and lower solutions" (or "supersolutions and subsolutions") for solving, both theoretically and numerically, second order elliptic PDEs (see Amann [4], Keller and Cohen [95], Keller [93,94], Sattinger [176]). Krasnosel'skii and Zabreiko [101] trace the use of positivity in functional analysis—closely related to monotone dynamics—to a 1924 paper by Uryson [222] on concave operators. The systematic use of positivity in PDEs was pioneered Krasnosel'skii and Ladyzhenskaya [100] and Krasnosel'skii [98].

Amann [5] showed how a sequence $\{u_n\}$ of approximate solutions to an elliptic problem can be viewed as the trajectory $\{T^n u_0\}$ of u_0 under a certain monotone map T in a suitable function space incorporating the boundary conditions, with fixed points of T being solutions of the elliptic equation. The dynamics of T can therefore be used to investigate the equation. Thus when T is globally asymptotically stable, there is a unique solution; while if T has two asymptotically stable fixed points, in many cases degree theory yields a third fixed point. As Amann [6] emphasized, a few key properties of T—continuity, monotonicity and some form of compactness—allow the theory to be efficiently formulated in terms of monotone maps in ordered Banach spaces.

Many questions in differential equations are framed in terms of eigenvectors of linear and nonlinear operators on Banach spaces. The usefulness of operators that are positive in some sense stems from the theorem of Perron [158] and Frobenius [51], now almost a century old, asserting that for a linear operator on $\mathbb{R}^n$ represented by a matrix with positive entries, the spectral radius is a simple eigenvalue having a positive eigenvector, and all other eigenvalues have smaller absolute value and only nonpositive eigenvectors. In 1912 Jentzsch [85] proved the existence of a positive eigenfunction with a positive eigenvalue for a homogeneous Fredholm integral equation with a continuous positive kernel.

In 1935 the topologists Alexandroff and Hopf [2] reproved the Perron–Frobenius theorem by applying Brouwer's fixed-point theorem to the action of a positive $n \times n$ matrix on the space of lines through the origin in $\mathbb{R}^n_+$. This was perhaps the first explicit use of the dynamics of operators on a cone to solve an eigenvalue problem. In 1940 Rutman [173] continued in this vein by reproving Jentzsch's theorem by means of Schauder's fixed-point theorem, also obtaining an infinite-dimensional analog of Perron–Frobenius, known today as the Krein–Rutman theorem [104,214]. In 1957 G. Birkhoff [20] initiated the dynamical use of Hilbert's projective metric for such questions.

The dynamics of cone-preserving operators continues to play an important role in functional analysis; for a survey, see Nussbaum [149,150]. One outgrowth of this work has been a focus on purely dynamical questions about such operators; some of these results are presented below. Polyhedral cones in Euclidean spaces have lead to interesting quantitative results, including *a priori* bounds on the number of periodic orbits. For recent work see Lemmens et al. [117], Nussbaum [151], Krause and Nussbaum [102], and references therein.

Monotone maps frequently arise as mathematical models. For example, the discrete Lotka–Volterra competition model (see May and Oster [136]):

$$\begin{aligned}(u_{n+1}, v_{n+1}) &= T(u_n, v_n)\\ &:= \bigl(u_n \exp\bigl[r(1 - u_n - bv_n)\bigr], v_n \exp\bigl[s(1 - cu_n - v_n)\bigr]\bigr)\end{aligned}$$

generates a monotone dynamical system relative to the fourth-quadrant cone only when the intrinsic rate of increase of each population is not too large ($r, s \leqslant 1$) and then only on the order interval $[0, r^{-1}] \times [0, s^{-1}]$ (Smith [192]). Fortunately in this case, every point in the first quadrant enters and remains in this order interval after one iteration. As is typical in ecological models, the Lotka–Volterra map is neither injective nor orientation-preserving or orientation-reversing. For monotone maps as models for the spread of a gene or an epidemic through a population, see Thieme [218], Selgrade and Ziehe [181], Weinberger [232], Liu [123] and the references therein.

5.2. *Definitions and basic results*

A continuous map $T : X \to X$ on the ordered metric space X is *monotone* if $x \leqslant y \Rightarrow Tx \leqslant Ty$, *strictly monotone* if $x < y \Rightarrow Tx < Ty$, *strongly monotone* if $x < y \Rightarrow Tx \ll Ty$, and *eventually strongly monotone* if whenever $x < y$, there exists $n_0 \geqslant 1$ such that $T^n x \ll T^n y$. We call T *strongly order-preserving* (*SOP*) if T is monotone, and whenever $x < y$ there exist respective neighborhoods U, V of x, y and $n_0 \geqslant 1$ such that $n \geqslant n_0 \Rightarrow T^n U \leqslant T^n V$.[1] As with semiflows, eventual strong monotonicity implies the strong order preserving property.

The orbit of x is $O(x) := \{T^n x\}_{n \geqslant 0}$, and the omega limit set of x is $\omega(x) := \bigcap_{k \geqslant 0} \overline{O(T^k x)}$. If $O(x)$ has compact closure, $\omega(x)$ is nonempty, compact, invariant (that is, $T\omega(x) = \omega(x)$) and *invariantly connected*. The latter means that $\omega(x)$ is not the disjoint union of two closed invariant sets [116].

If $T(x) = x$ then x is a *fixed point* or *equilibrium*. E denotes the set of fixed points. More generally, if $T^k x = x$ for some $k \geqslant 1$ we call x *periodic*, or k-periodic. The minimal such k is called the period of x (and $O(x)$).

Let Y denotes an ordered Banach space with order cone Y_+. A linear operator $A \in L(Y)$ is called *positive* if $A(Y_+) \subset Y_+$ (equivalently, A is a monotone map) and *strongly positive* if $A(Y_+ \setminus \{0\}) \subset \operatorname{Int} Y_+$) (equivalently, A is a strongly monotone map).

The following result is useful for proving smooth maps monotone or strongly monotone:

LEMMA 5.1. *Let $X \subset Y$ be a p-convex set and $f : X \to Y$ a locally C^1 map with quasiderivative $h : U \to L(Y)$ defined on an open set $U \subset Y$. If the linear maps $h(x) \in L(Y)$ are positive* (*respectively, strongly positive*) *for all $x \in U$, then f is monotone* (*respectively, strongly monotone*).

PROOF. By p-convexity it suffices to prove that every $p \in X$ has a neighborhood N such that $f|N \cap X$ is monotone (respectively, strongly monotone). We take N to be an open ball in U centered at p. Suppose $p + z \in X \cap N$, $z > 0$. By p-convexity, $X \cap N$ contains the line segment from p to $p + z$. The definition (above Lemma 2.15) of locally C^1 implies that the map $g : [0, 1] \to Y$, $t \mapsto f(p + tz)$ is C^1 with $g'(t) = h(tz)z$. Therefore

$$f(p+z) - f(z) = g(0) - g(1) = \int_0^1 g'(t)\,\mathrm{d}t = \int_0^1 h(tz)z\,\mathrm{d}t.$$

Because $h(tz) \in L(Y)$ is positive and $z > 0$, we have $h(tz)z \in Y_+$, therefore $f(p + z) - f(p) \geqslant 0$. If the operators $h(tz)$ are strongly positive, $f(p+z) - f(p) \gg 0$. $\square$

PROPOSITION 5.2 (Nonordering of Periodic Orbits). *A periodic orbit of a monotone map is unordered.*

---

[1] Our use of “strongly order-preserving” conflicts with Dancer and Hess [38], who use these words to mean what we have defined as “strongly monotone”. Our usage is consistent with that of several authors. Takáč [208,209] uses “strongly increasing” for our SOP.

PROOF. If not, there exists x in the orbit such that $T^k(x) > x$ for some $k > 0$. Induction on n shows that $T^{nk}(x) > x$ for all $n > 0$. But if x has period $m > 0$, induction on k proves that $T^{mk}(x) = x$. ☐

LEMMA 5.3 (Monotone Convergence Criterion). *Assume T is monotone and $O(z)$ has compact closure. If $m \geqslant 1$ is such that $T^m z < z$ or $T^m z > z$ then $\omega(z)$ is an m-periodic orbit.*

PROOF. Consider first the case $m = 1$. Compactness of $\overline{O(z)}$ implies the decreasing sequence $\{T^k z\}$ converges to a point $p = \omega(x)$. Now suppose $m > 1$. Applying the case just proved to the map T^m, we conclude that $\{T^{km} z\}$ converges to a point $p = T^m(p)$. It follows that $\omega(z) = \{p, Tp, T^2 p, \ldots, T^{m-1} p\}$. ☐

Lemma 5.3 yields information on one-sided stability of compact limit sets when T is SOP; see Hirsch [70].

In order to state the following lemma succinctly, we call a set $J \subset \mathbb{N}$ an *interval* if it is nonempty and contains all integers between any two of its members. For $a, b \in \mathbb{N}$ we set $[a, b] = \{j \in \mathbb{N}\colon a \leqslant j \leqslant b\}$ (there will be no confusion with real intervals). Two intervals *overlap* if they have more than one point in common.

Let $J \subset \mathbb{N}$ be an interval and $f : J \to X$ be a map. A subinterval $[a, b] \subset J$, $a < b$ is *rising* if $f(a) < f(b)$, and *falling* if $f(b) < f(a)$.

THEOREM 5.4. *A trajectory of a monotone map cannot have both a rising interval and a falling interval.*

PROOF. Follows from Theorem 1.6. ☐

LEMMA 5.5. *If T is monotone, $\omega(z)$ cannot contain distinct points having respective neighborhoods U, V such that $T^r(U) \leqslant T^r(V)$ for some $r \geqslant 0$.*

PROOF. Follows from Theorem 5.4 (see proof of Lemma 1.7). ☐

The next result is fundamental to the theory of monotone maps:

THEOREM 5.6 (Nonordering Principle). *Let $\omega(z)$ be an omega limit set for a monotone map T.*

(i) *No points of $\omega(z)$ are related by $\ll$.*

(ii) *If $\omega(z)$ is a periodic orbit or T is SOP, no points of $\omega(z)$ are related by $<$.*

PROOF. Follows from Proposition 5.2 and Lemma 5.5 (see the proof of Theorem 1.8). ☐

Call x *convergent* if $\omega(x)$ is a fixed point, and *quasiconvergent* if $\omega(x) \subset E$. Just as for semiflows, Proposition 5.6 leads immediately to a convergence criterion:

COROLLARY 5.7. *Assume Φ is SOP.*

(i) *If an omega limit set has a supremum or infimum, it reduces to a single fixed point.*

(ii) *If the fixed point set is totally ordered, every quasiconvergent point with compact orbit closure is convergent.*

PROOF. Part (i) follows from Theorem 5.6(ii), since the supremum or infimum, if it exists, belongs to the limit set. Part (ii) is a consequence (i). ☐

5.2.1. *Failure of the limit set dichotomy* We now point out a significant difference between strongly monotone maps and semiflows:

The Limit Set Dichotomy fails for strongly monotone maps.

Recall that for an SOP semiflow with compact orbit closures, the dichotomy (Theorem 1.16) states:

If $a < b$, either $\omega(a) < \omega(b)$ or $\omega(a) = \omega(b) \subset E$.

Takáč [211, Theorem 3.10], gives conditions on strongly monotone maps under which $a < b$ implies that either $\omega(a) \cap \omega(b) = \emptyset$ or $\omega(a) = \omega(b)$. He also gives a counterexample showing that $\omega(a) \cap \omega(b) = \emptyset$ does not imply $\omega(a) < \omega(b)$, nor does $\omega(a) = \omega(b)$ imply that these limit sets consist of fixed points (they are period-two orbits in his example). However, the mapping in his example is defined on a disconnected space.

For any map T in a Banach space, having an asymptotically stable periodic point p of period > 1, the Limit Set Dichotomy as formulated above must fail: take a point $q > p$ so near to p that $O(p) = \omega(p) = \omega(q)$. Clearly $\omega(p)$, being a nontrivial periodic orbit, contains no fixed points. Thus the second assertion of the Limit Set Dichotomy fails in this case.

Dancer and Hess [38] gave a simple example in $\mathbb{R}^k$ for prime k of a strongly monotone map with an asymptotically stable periodic point of period k which we describe below. Therefore the second alternative of the Limit Set Dichotomy can be no stronger than that $\omega(a) = \omega(b)$ is a periodic orbit.

The Limit Set Dichotomy fails even for strictly monotone maps in $\mathbb{R}^2$. Let $f(x) = 2\arctan(x)$, let $a > 0$ be its unique positive fixed point, and note that $0 < f'(a) < 1$. Define $T_0 : \mathbb{R}^2 \to \mathbb{R}^2$ by $T_0(x, y) := (f(y), f(x))$. Then $E = \{(-a, -a), (0, 0), (a, a)\}$ since f has no points of period 2. The fixed points of T_0^2 are the nine points obtained by taking all pairings of $-a, 0, a$. An easy calculation shows that $\{(-a, a), (a, -a)\}$ is an asymptotically stable period-two orbit of T_0 because the Jacobian matrix of T_0^2 is $f'(a)^2$ times the identity matrix. T^0 is strictly monotone but not strongly monotone. Now consider the perturbations $T_\epsilon(x, y) := T_0(x, y) + (\epsilon x, \epsilon y)$. It is easy to see that T_ϵ is strongly monotone for $\epsilon > 0$; and by the implicit function theorem, for small $\epsilon > 0$, T_ϵ has an asymptotically stable period-two orbit $O(p_\epsilon)$ with p_ϵ near $(-a, a)$. As noted in [38], this example can be generalized to $\mathbb{R}^k$ for prime k.

Takáč [212] shows that linearly stable periodic points can arise for the period map associated with monotone systems of ordinary and partial differential equations. Other counterexamples for low-dimensional monotone maps can be found in Smith [192,195].

As we have shown, asymptotically stable periodic orbits that are not singletons can exist for monotone, even strongly monotone maps. Later we will show that the generic orbit of a smooth, dissipative, strongly monotone map converges to a periodic orbit. Here, we show that every attractor contains a stable periodic orbit.

Recall that a point p is *wandering* if there exists a neighborhood U of p and a positive integer n_0 such that $T^n(U) \cap U = \emptyset$ for $n > n_0$. The *nonwandering set* Ω, consisting of all points q that are not wandering, contains all limit sets. In the following, we assume that X is an open subset of the strongly ordered Banach space Y and $T : X \to X$ is monotone with compact orbit closures. The following result is adapted from Hirsch [71, Theorems 4.1, 6.3].

THEOREM 5.8. *If T is strongly monotone and K is a compact attractor, then K contains a stable periodic orbit.*

The proof relies on the following result that does not use strong monotonicity nor that K attracts uniformly:

THEOREM 5.9. *Let $p \in K$ be a maximal* (*resp., minimal*) *nonwandering point. Then p is periodic, and every neighborhood of p contains an open set $W \gg p$* (*resp., $W \ll p$*) *such that $\omega(x) = O(p)$ for all $x \in W$.*

PROOF. Suppose K attracts the open neighborhood U of K and fix $y \gg p,\ y \in U$. Since p is nonwandering there exists a convergent sequence $x_i \to p$ and a sequence $n_i \to \infty$ such that $T^{n_i} x_i \to p$. For all large i, $x_i \leqslant y$. Passing to a subsequence, we assume that $T^{n_i} y \to q$. By monotonicity and $x_i \leqslant y$ for large i, we have $q \geqslant p$. But $q \in K \cap \Omega$ and the maximality of p requires $q = p$. Since $p \ll y$ and $T^{n_i} y \to p$ it follows that $T^m y \ll y$ for some m. Lemma 5.3 implies that $\omega(y)$ is an m-periodic orbit containing p. As this holds for every $y \gg p$, the result follows. □

LEMMA 5.10. *Let $p, q \in K$ be fixed points such that $p \ll q$, p is order stable from below, and q is order stable from above. Then $K \cap [p, q]$ contains a stable equilibrium.*

PROOF. Let R be a maximal totally ordered set of fixed points in $K \cap [p, q]$. An argument similar to the one in the proof of Theorem 1.30 shows that the fixed point

$$e := \inf\{z \in E \cap R\colon\ z \text{ is order stable from above}\}$$

is order stable. That e is stable follows from the analog of Proposition 1.28. □

PROOF OF THEOREM 5.8. Theorem 5.9 shows that some iterate T^n, $n \geqslant 0$ has fixed points p, q as in Lemma 5.10, which result therefore implies Theorem 5.8. □

Jiang and Yu [90, Theorem 2] implies that if T is analytic, order compact with strongly positive derivative, then K must contain an asymptotically stable periodic orbit.

5.3. *The order interval trichotomy*

In this section we assume that X is a subset of an ordered Banach space Y with positive cone Y_+, with the induced order and topology. Much of the early work on monotone maps on ordered Banach spaces focused on the existence of fixed points for self maps of order intervals $[a,b]$ such that $a,b \in E$; see especially Amann [6]. The following result of Dancer and Hess [38], quoted without proof, is crucial for analyzing such maps.

Let u,v be fixed points of T. A doubly-infinite sequence $\{x_n\}_{n\in\mathbb{Z}}$ ($\mathbb{Z}$ is the set of all integers) in Y is called an *entire orbit from* u *to* v if

$$x_{n+1} = T(x_n), \qquad \lim_{n\to-\infty} x_n = u, \quad \lim_{n\to\infty} x_n = v.$$

If $x_n \leqslant x_{n+1}$ (respectively, $x_n < x_{n+1}$), the entire orbit is *increasing* (respectively, *strictly increasing*). If $x_n \geqslant x_{n+1}$ (respectively, $x_n > x_{n+1}$), the entire orbit is *decreasing* (respectively, *strictly decreasing*). If the entire orbit $\{x_n\}$ is increasing but not strictly increasing, then $x_n = v$ for all sufficiently large n; and similarly for decreasing.

Consider the following hypothesis:

(G) $X = [a,b]$ where $a,b \in Y$, $a < b$ and $Ta = a$, $Tb = b$. The map $T : X \to X$ is monotone and $T(X)$ has compact closure in X.

THEOREM 5.11 (The Order Interval Trichotomy). *Under hypothesis* (G), *at least one of the following holds*:

(a) *there is a fixed point* c *such that* $a < c < b$;

(b) *there exists an entire orbit from* a *to* b *that is increasing, and strictly increasing if* T *is strictly monotone*;

(c) *there exists an entire orbit from* b *to* a *that is decreasing, and strictly decreasing if* T *is strictly monotone.*

An extension of Theorem 5.11 to allow additional fixed points on the boundary of $[a,b]$ is carried out in Hsu et al. [83]. Wu et al. [236] weaken the compactness condition. See Hsu et al. [83], Smith [192], and Smith and Thieme [201] for applications to generalized two-species competition dynamics. For related results see Hess [63], Matano [133], Poláčik [162], Smith [184,194].

A fixed point q of T is *stable* if every neighborhood of q contains a positively invariant neighborhood of q. An immediate corollary of the Order Interval Trichotomy is:

COROLLARY 5.12. *Assume hypothesis* (G), *and let* a *and* b *be stable fixed points. Then there is a third fixed point in* $[a,b]$.

Corollary 5.14 establishes a third fixed point under different assumptions.

In general, more than one of the alternatives (a), (b), (c) may hold (see [83]). The following complement to the Order Interval Trichotomy gives conditions for exactly one to hold; (iii) is taken from Proposition 2.2 of [83].

Consider the following three conditions:

(a′) there is a fixed point c such that $a < c < b$;
(b′) there exists an entire orbit from a to b;
(c′) there exists an entire orbit from b to a.

PROPOSITION 5.13. *Assume hypothesis* (G).

(i) *If T is strongly order-preserving, exactly one of* (a′), (b′), (c′) *can hold. More precisely*: *Assume $a < y < b$ and y has compact orbit closure. Then $\omega(y) = \{b\}$ if there is an entire orbit from a to b, while $\omega(y) = \{a\}$ if there is an entire orbit from b to a.*
(ii) *If $a \ll b$, at most one of* (b′), (c′) *can hold.*
(iii) *Suppose $a \ll b$, and $E \cap [a, b] \setminus \{a, b\} \neq \emptyset$ implies $E \cap [[a, b]] \setminus \{a, b\} \neq \emptyset$. Then at most one of* (a′), (b′), (c′) *can hold.*

PROOF. For (i), consider an entire orbit $\{x_n\}$ from a to b. There is a neighborhood U of a such that $T^k U \leqslant T^k y$ for sufficiently large k. Choose $x_j \in U$. Then $T^k x_j \leqslant T^k y \leqslant b$ for all large k. As $\lim_{k\to\infty} T^k x_j = b$ and the order relation is closed, b is the limit of every convergent subsequence of $\{T^k y\}$. The case of an entire orbit from b to a is similar.

In (ii), choose neighborhoods U, V of a, b respectively such that $U \ll V$. Fix j so that $x_j \in U$. If $y \in V$ then an argument similar to the proof of (i) shows that $\omega(y) = \{b\}$. Hence there cannot be an entire orbit from b to a, since it would contain a point of V.

Assume the hypothesis of (iii), and note that (ii) makes (b′) and (c′) incompatible. If (a′), there is a fixed point $c \in [[a, b]]$, and arguments similar to the proof of (ii) show that neither (b′) nor (c′) holds. □

COROLLARY 5.14. *In addition to hypothesis* (G), *assume T is strongly order preserving with precompact image. If some trajectory does not converge, there is a third fixed point.*

PROOF. Follows from the Order Interval Trichotomy 5.11 and Proposition 5.13(i). □

A number of authors have considered the question of whether *a priori* knowledge that every fixed point is stable implies the convergence of every trajectory. See Alikakos et al. [3], Dancer and Hess [38], Matano [133] and Takáč [209] for such results. The following theorem is adapted from [38].

A set $A \subset X$ is a *uniform global attractor* for the map $T : X \to X$ if $T(A) = A$ and $\operatorname{dist}(T^n x, A) \to 0$ uniformly in $x \in X$.

THEOREM 5.15. *Let $a, b \in Y$ with $a < b$. Assume $T : [a, b] \to [a, b]$ is strongly order preserving with precompact image, and every fixed point is stable. Then E is a totally ordered arc J that is a uniform global attractor, and every trajectory converges.*

PROOF. We first show that there exists a totally ordered arc of fixed points; this will not use the SOP property. $O(a)$ is an increasing sequence converging to the smallest fixed point in $[a, b]$. Similarly, $O(b)$ is a decreasing sequence converging to the largest fixed point in $[a, b]$. By renaming a and b as these fixed points, we may as well assume that $a, b \in E$. The stability hypothesis and Corollary 5.12 implies there is a fixed point c satisfying $a < c < b$.

The same reasoning applies to $[a,c]$ and $[c,b]$, and can be repeated indefinitely to show that every maximal totally ordered set of fixed points is compact and connected, hence an arc (Wilder [233, Theorem I.11.23]). Thus by Zorn's Lemma there is a totally ordered arc $J \subset E$ joining a to b.

Next we prove: *Every unordered compact invariant set K is a point of J.* This will not use precompactness of $T([a,b])$. Set $q = \inf\{e \in J\colon\ K \leqslant e\}$. It suffices to prove $q \in K$, for then K, being unordered, reduces to $\{q\}$. If $q \notin K$ then $q > k$. By SOP and invariance of K there is a are neighborhoods V of p and $n > 0$ such that $K = T^n(K) \leqslant T(V)$, hence $K \leqslant T^n(V \cap J) = V \cap J$. This gives the contradiction $K \leqslant \inf(V \cap J) < q$.

Every $\omega(x)$ is compact by the precompactness assumption, and unordered by the Nonordering Principle 5.6(ii). Total ordering of J therefore implies $\omega(x)$ is a point of J. This proves every trajectory converges.

To show that J is a global attractor, let N be the open ϵ-neighborhood of J for an arbitrary $\epsilon > 0$. The stability hypothesis implies N contains a positively invariant open neighborhood W of J. It suffices to prove $T^n(X) \subset W$ when n is sufficiently large. Convergence of all trajectories implies that for every $x \in X$ there exists an open neighborhood $U(x)$ of x and $n(x) > 0$ such that $T^n(x) \in W$ for all $n \geqslant n(x)$. Precompactness of $T(X)$ implies $T(X) \subset \bigcup U(x_i)$ for some finite set $\{x_i\}$. Hence $T^n(X) \subset W$ provided $n > \max\{n(x_i)\}$. □

If the map T in Theorem 5.15 is C^1 and strongly monotone, then E is a smooth totally ordered arc by a result of Takáč [211].

5.3.1. *Existence of fixed points*

Dancer [37] obtained remarkable results concerning the dynamics of monotone maps with some compactness properties: Limit sets can always be bracketed between two fixed points, and with additional hypotheses these fixed points can be chosen to be stable. The next two theorems are adapted from [37].

A map $T : Y \to Y$ is *order compact* if it takes each order interval, and hence each order bounded set, into a precompact set.

THEOREM 5.16. *Let X be an order convex subset of Y. Assume that $T : X \to X$ is monotone and order compact, with every orbit having compact closure in X and every omega limit set order bounded. Then for all $z \in Y$ there are fixed points f, g such that $f \leqslant \omega(z) \leqslant g$.*

PROOF. There exists $u \in X$ such that $u \geqslant \omega(z)$ because omega limit sets order bounded. Since $T(\omega(z)) = \omega(z)$, it follows that $\omega(z) \leqslant T^i u$ for all i, hence $\omega(z) \leqslant \omega(u)$. Similarly, there exists $s \in X$ such that $\omega(u) \leqslant \omega(s)$. The set $F := \{x \in Y\colon\ \omega(z) \leqslant x \leqslant \omega(s)\}$ is the intersection of closed order intervals, hence closed and convex, nonempty because it contains $\omega(u)$, and obviously order bounded. Moreover $F \subset X$ because X is order convex. Therefore $T(F)$ is defined and is precompact. Monotonicity of T and invariance of $\omega(z)$ and $\omega(s)$ imply $T(F) \subset F$. It follows from the Schauder fixed point theorem that there is a fixed point $g \in F$, and $g \geqslant \omega(z)$ as required. The existence of f is proved similarly. □

The cone Y_+ is *reproducing* if $Y = Y_+ - Y_+$. This holds for many function spaces whose norms do not involve derivatives. If Y_+ has nonempty interior, it is reproducing: any $x \in Y$

can be expressed as $x = \lambda e - \lambda(e - \lambda^{-1}x) \in Y_+ - Y_+$, where $e \gg 0$ is arbitrary and $\lambda > 0$ is a sufficiently large real number.

THEOREM 5.17. *Let $X \subset Y$ be order convex. Assume $T : X \to X$ is monotone, completely continuous, and order compact. Suppose orbits are bounded and omega limits sets are order bounded.*

(i) *For all $z \in X$ there are fixed points f, g such that $f \leqslant \omega(z) \leqslant g$.*

(ii) *Assume Y_+ is reproducing, $X = Y$ or Y_+, and E is bounded. Then there are fixed points $e_M = \sup E$ and $e_m = \inf E$, and all omega limit sets lie in $[e_m, e_M]$. Moreover, if $x \leqslant e_m$ then $\omega(x) = \{e_m\}$, while if $x \geqslant e_M$ then $\omega(x) = \{e_M\}$.*

(iii) *Assume Y_+ is reproducing, $X = Y$ or Y_+, E is bounded, and T is strongly order preserving. Suppose $z_0 \in Y$ is not convergent. Then there are three fixed points $f < p < g$ such that $f < \omega(z_0) < g$. If T is strongly monotone, f and g can be chosen to be stable.*

PROOF. We prove all assertions except for the stability in (iii). Complete continuity implies that every positively invariant bounded set is precompact. Therefore orbit closures are compact and omega limit sets are compact and nonempty, so (i) follows from Theorem 5.16.

To prove (ii), note that E is compact because it is bounded invariant and closed. Choose a maximal element $e_M \in E$ (Lemma 1.1). We must show that $e_M \geqslant e$ for every $e \in E$. Since the order cone is reproducing, $e_M - e = v - w$ with $v, w \geqslant 0$. Set $u := e + v + w$. Then $u \in X$, $u \geqslant e$, and $u \geqslant e_M$. Monotonicity implies $e_M = T^i e_M \leqslant T^i u$ for all $i \geqslant 0$, hence $e_M \leqslant \omega(u)$. By Theorem 5.16 there exists $g \in E$ such that $\omega(u) \leqslant g$. Hence $e_M \leqslant g$, whence $e_M = g$ by maximality. We now have $e_M \leqslant \omega(u) \leqslant g = e_M$, so $\omega(u) = \{e_M\}$. Monotonicity implies (as above) $e \leqslant \omega(u)$, therefore $e \leqslant e_M$ as required. This proves $e_M = \sup E$, and the dual argument proves $e_m = \inf E$. If $x \leqslant e_m$ then $\omega(x) \leqslant e_m$ by monotonicity; but $\omega(x) \geqslant e_m$ by (i), so $\omega(x) = \{e_m\}$. Similarly for the case $x \geqslant e_M$.

To prove the first assertion of (iii), note that $e_m < \omega(z) < e_M$ by (i) and the Nonordering Principle 5.6(ii). Monotonicity and order compactness of T imply $[e_m, e_M]$ is positively invariant with precompact image. As T is SOP, there is a third fixed point in $[e_m, e_M]$ by Corollary 5.14. □

5.4. *Sublinearity and the cone limit set trichotomy*

Motivated by the problem of establishing the existence of periodic solutions of quasimonotone, periodic differential equations defined on the positive cone in R^n, Krasnosel'skii pioneered the dynamics of sublinear monotone self-mappings of the cone [99]. We will prove Theorem 5.20 below, adapted from the original finite-dimensional version of Krause and Ranft [103].

Let Y denote an ordered Banach space with positive cone Y_+. Denote the interior (possibly empty) of Y_+ by P. A map $T : Y_+ \to Y_+$ is *sublinear* (or "subhomogeneous") if

$$0 < \lambda < 1 \implies \lambda T(x) \leqslant T(\lambda x),$$

and *strongly sublinear* if

$$0 < \lambda < 1,\ x \gg 0 \quad \Longrightarrow \quad \lambda T(x) \ll T(\lambda x).$$

Strong sublinearity is the strong concavity assumption of Krasnosel'skii [99]. It can be verified by using the following result from that monograph:

LEMMA 5.18. *$T : P \to Y$ is strongly sublinear provided T is differentiable and $Tx \gg T'(x)x$ for all $x \gg 0$.*

PROOF. Let $F(s) = s^{-1}T(sx)$ for $s > 0$ and some fixed $x \gg 0$. Then $F'(s) = -s^{-2}T(sx) + s^{-1}T'(sx)x \ll 0$ by our hypothesis. So for $0 < \lambda < 1$, we have

$$\phi\big(Tx - \lambda^{-1}T(\lambda x)\big) = \phi\big(F(1)\big) - \phi\big(F(\lambda)\big) < 0$$

for every nontrivial $\phi \in Y_+^*$, the dual cone in Y^*, because $\frac{\mathrm{d}}{\mathrm{d}s}\phi(F(s)) < 0$. The desired conclusion follows from Proposition 3.1. $\square$

COROLLARY 5.19. *Assume Y is strongly ordered. A continuous map $T : Y_+ \to Y$ is sublinear provided T is differentiable in P and $Tx \geqslant T'(x)x$ for all $x \gg 0$.*

PROOF. By continuity it suffices to prove $T|P$ is sublinear. Fix $e \gg 0$. For each $\delta > 0$ the map $P \to Y$, $x \mapsto Tx + \delta e$ is strongly sublinear by Lemma 5.18. Sending δ to zero implies T is sublinear. $\square$

Krause and Ranft [103] have results establishing sublinearity of some iterate of T, which is an assumption used in Theorem 5.20 below.

The following theorem demonstrates global convergence properties for order compact maps that are monotone and sublinear in a suitably strong sense.

THEOREM 5.20 (Cone Limit Set Trichotomy). *Assume $T : Y_+ \to Y_+$ is continuous and monotone and has the following properties for some $r \geqslant 1$:*

(a) *T^r is strongly sublinear*;
(b) *$T^r x \gg 0$ for all $x > 0$*;
(c) *T^r is order compact.*

Then precisely one of the following holds:

(i) *each nonzero orbit is order unbounded*;
(ii) *each orbit converges to* 0, *the unique fixed point of T*;
(iii) *each nonzero orbit converges to $q \gg 0$, the unique nonzero fixed point of T.*

A key tool in the proofs of such results is Hilbert's projective metric and the related part metric due to Thompson [219]. We define the part metric $\mathsf{p}(x, y)$ here in a very limited way, as a metric on P (which is the "part"). For $x, y \gg 0$, define

$$\mathsf{p}(x, y) := \inf\big\{\rho > 0\colon\ \mathrm{e}^{-\rho}x \ll y \ll \mathrm{e}^{\rho}y\big\}.$$

The family of open order intervals in P forms a base for the topology of the part metric. It is easy to see that the identity map of P is continuous from the original topology on P to that defined by the part metric.

When $Y = \mathbb{R}^n$ with vector ordering, with $P = \mathrm{Int}(\mathbb{R}^n_+)$, the part metric is isometric to the max metric on $\mathbb{R}^n$, defined by $d_{\max}(x, y) = \max_i |x_i - y_i|$, *via* the homeomorphism $\mathrm{Int}(\mathbb{R}^n_+) \approx \mathbb{R}^n$, $x \mapsto (\log x_1, \dots, \log x_n)$. Restricted to compact sets in $\mathrm{Int}(\mathbb{R}^n_+)$, the part metric and the max metric are equivalent in the sense that there exist $\alpha, \beta > 0$ such that $\alpha \mathsf{p}(x, y) \leqslant |x - y|_{\max} \leqslant \beta \mathsf{p}(x, y)$.

The usefulness of the part metric in dynamics stems from the following result. Recall map T between metric spaces is a *contraction* if it has a Lipschitz constant < 1, and it is *nonexpansive* if it has Lipschitz constant 1. We say T is *strictly nonexpansive* if $\mathsf{p}(Tx, Ty) < \mathsf{p}(x, y)$ whenever $x \neq y$.

PROPOSITION 5.21. *Let $T : P \to P$ be a continuous, monotone, sublinear map.*

- (i) *T is nonexpansive for the part metric.*
- (ii) *If T is strongly sublinear, T is strictly nonexpansive for the part metric.*
- (iii) *If T is strongly monotone, $A \subset P$, and no two points of A are linearly dependent, then $T|_A$ is strictly nonexpansive for the part metric.*
- (iv) *Under the assumptions of* (ii) *or* (iii), *if $L \subset A$ is compact* (*in the norm topology*) *and $T(L) \subset L$, then the set $L_\infty = \bigcap_{n>0} T^n(L)$ is a singleton.*

PROOF. Fix distinct points $x, y \in A$ and set $\mathrm{e}^{\mathsf{p}(x,y)} = \lambda > 1$, so that $\lambda^{-1}x \leqslant y \leqslant \lambda x$ and λ is the smallest number with this property. By sublinearity and monotonicity,

$$\lambda^{-1}Tx \leqslant T\big(\lambda^{-1}x\big) \leqslant Ty \leqslant T(\lambda x) \leqslant \lambda Tx \tag{5.3}$$

which implies $\mathsf{p}(Tx, Ty) \leqslant \mathsf{p}(x, y)$.

If T is strongly sublinear, the first and last inequalities in (5.3) can be replaced by $\ll$, which implies $\mathsf{p}(Tx, Ty) < \mathsf{p}(x, y)$.

When x and y are linearly independent, $\lambda^{-1}x < y < \lambda x$. If also T is strongly monotone, (5.3) is strengthened to

$$\lambda^{-1}Tx \leqslant T\big(\lambda^{-1}x\big) \ll Ty \ll T(\lambda x) \leqslant \lambda Tx$$

which also implies $\mathsf{p}(Tx, Ty) < \mathsf{p}(x, y)$.

To prove (iv), observe first that if L is compact in the norm metric, it is also compact in the part metric. In both (ii) and (iii) T reduces the diameter in the part metric of every compact subset of L. Since T maps L_∞ onto itself but reduces its part metric diameter, (iv) follows. □

PROOF OF THE CONE LIMIT SET TRICHOTOMY 5.20. We first work under the assumption that $r = 1$. In this case Proposition 5.21 shows that every compact invariant set in P reduces to a fixed point, and there is at most one fixed point in P. It suffices to consider the orbits of points $x \in P$, by (b).

Suppose there is a fixed point $q \gg 0$. There exist numbers $0 < \lambda < 1 < \mu$ such that $x \in [\lambda q, \mu q] \subset P$. For all n we have

$$0 \ll \lambda q = \lambda T^n q \leqslant T^n(\lambda q) \leqslant T^n x \leqslant T^n(\mu q) \leqslant \mu T^n q = \mu q.$$

Hence $O(x) \subset [\lambda q, \mu q]$, so $O(Tx)$ lies in $T([\lambda p, \mu q])$, which is precompact by (c). Therefore $\omega(x)$ is a compact unordered invariant set in P. Proposition 5.21(iii) implies that $\omega(x) = \{q\}$. This verifies (iii).

Case I: If some orbit $O(y)$ is order unbounded, we prove (i). We may assume $y \gg 0$. There exists $0 < \gamma < 1$ such that $\gamma y \ll x$. Then $\gamma T^n y \leqslant T^n(\gamma y) \leqslant T^n x$, implying $O(x)$ is unbounded.

Case II: If $0 \in \omega(y)$ for some y, we prove (ii). We may assume $y \gg 0$. Fix $\mu > 1$ with $x \ll \mu y$. Then $0 \leqslant T^n x \leqslant T^n(\mu y) \leqslant \mu T^n y \to 0$. Therefore $\overline{O(x)}$ is compact and $T^n x \to 0$.

Case III: If the orbit closure $\overline{O(x)} \subset [a, b] \subset P$, then (iii) holds. For $\overline{O(x)}$ is compact by (c), so $\omega(x)$ is a nonempty compact invariant set. Because $\omega(x) \subset \overline{O(x)} \subset P$, Case I implies (iii).

Cases I, II and III cover all possibilities, so the proof for $r = 1$ is complete. Now assume $r > 1$. One of the statements (i), (ii), (iii) is valid for T^r in place of T. If (i) holds for T^r, it obviously holds for T. Assume (ii) holds for T^r. If $x > 0$ then $\omega(x) = \{0, T(0), \dots, T^{r-1}(0)\}$. As this set is compact and T^r invariant, it reduces to $\{0\}$, verifying (ii) for T. A similar argument shows that if (iii) holds for T^r, it also holds for T. □

The conclusion of the Cone Limit Trichotomy can fail for strongly monotone sublinear maps—simple linear examples in the plane have a line of fixed points. But the following holds:

THEOREM 5.22. *Assume*:

(a) *$T : Y_+ \to Y_+$ is continuous, sublinear, strongly monotone, and order compact*;

(b) *for each $x > 0$ there exists $r \in \mathbb{N}$ such that $T^r x \gg 0$.*

Then:

(i) *either $O(x)$ is not order bounded for all $x > 0$, or $O(x)$ converges to a fixed point for all $x \geqslant 0$;*

(ii) *the set of fixed points > 0 has the form $\{\lambda e\colon\ a \leqslant \lambda \leqslant b\}$ where $e \gg 0$ and $0 \leqslant a \leqslant b \leqslant \infty$.*

PROOF. Let $y > 0$ be arbitrary. If $O(y)$ is not order bounded, or $0 \in \omega(y)$, the proof of (i) follows Cases I and II in the proof of the Cone Limit Set Trichotomy 5.20. If $\overline{O(x)} \subset [a, b] \subset P$, then $\omega(y)$ is a compact invariant set in P, as in Case III of 5.20. As $\omega(y)$ is unordered, every pair of its elements are linearly independent. Therefore Proposition 5.21(iv) implies $\omega(y)$ reduces to a fixed point, proving (i). The same reference shows that all fixed points lie on a ray $R \subset Y_+$ through the origin, which must pass through some

$e \gg 0$ by (b). Suppose p, q are distinct fixed points and $0 \ll p \ll x <\ll q$. There exist unique numbers $0 < \mu < 1 < \nu$ such that $x = \mu p = \mu q$. Then

$$Tx \geqslant \mu Tp = \mu p = x, \qquad Tx \leqslant \nu Tq = \nu q = x$$

proving $Tx = x$. This implies (ii). □

Papers related to sublinear dynamics and the part metric include Dafermos and Slemrod [35], Krause and Ranft [103], Krause and Nussbaum [102], Nussbaum [149,150], Smith [183], and Takáč [208,215]. For interesting applications of sublinear dynamics to higher order elliptic equations, see Fleckinger-Pellé and Takáč [45,46].

5.5. *Smooth strongly monotone maps*

Smoothness together with compactness allows one to settle questions of stability of fixed points and periodic points by examining the spectrum of the linearization of the mapping. Let $T : X \to X$ where X is an open subset of the ordered Banach space Y with cone Y_+ having nonempty interior in Y. Assume that T is a completely continuous, C^1 mapping with a strongly positive derivative at each point. Then T is strongly monotone by Lemma 5.1 and $T'(x)$ is a Krein–Rutman operator so the Krein–Rutman Theorem 2.17 holds for $T'(p)$, $p \in E$. Let ρ be the spectral radius of $T'(p)$, which the reader will recall is a simple eigenvalue which dominates all others in modulus and for which the generalized eigenspace is spanned by an eigenvector $v \gg 0$. Let V_1 be the span of v in Y. There is a complementing closed subspace V_2 such that $Y = V_1 \oplus V_2$ satisfying $T'(p)V_2 \subset V_2$ and $V_2 \cap Y_+ = \{0\}$. Let P denote the projection of Y onto V_2 along v. Finally, let τ denote the spectral radius of $T'(p)|V_2 : V_2 \to V_2$, which obviously satisfies $\tau < \rho$. Mierczyński [139] exploits this structure of the linearized mapping to obtain very detailed behavior of the orbits of points near p. In order to describe his results, define $K := \{x \in X\colon\ T^n x \to p\}$ to be the basin of attraction of p. Let $M_- := \{x \in X\colon\ T^{n+1} \ll T^n x, n \geqslant n_0,\ \text{some } n_0\}$ be the set of eventually decreasing orbits, $M_+ := \{x \in X\colon\ T^n x \ll T^{n+1}x, n \geqslant n_0,\ \text{some } n_0\}$ be the set of eventually increasing orbits, and $M := M_- \cup M_+$ be the set of eventually monotone (in the strong sense) orbits.

The following result is standard but nonetheless important.

THEOREM 5.23 (Principle of Linearized Stability). *If $\rho < 1$, there is a neighborhood U of p such that $T(U) \subset U$ and constants $c > 0$, $\kappa \in (\rho, 1)$ such that for each $x \in U$ and all n*

$$\left\| T^n x - p \right\| \leqslant c\kappa^n \|x - p\|.$$

In the more delicate case that $\rho \leqslant 1$, Mierczyński [139] obtains a smooth hypersurface C, which is an analog for T of the codimension-one linear subspace V_2 invariant under the linearized mapping $T'(p)$:

THEOREM 5.24. *If* $\rho \leqslant 1$ *there exists a codimension-one embedded invariant manifold* $C \subset X$ *of class* C^1 *having the following properties*:

(i) $C = \{x + Pw + R(w)v\colon\ w \in O\}$ *where* $R : O \to \mathbb{R}$ *is a* C^1 *map defined on the relatively open subset* O *of* V_2 *containing* 0, *satisfying* $R(0) = R'(0) = 0$. *In particular,* C *is tangent to* V_2 *at* p.

(ii) C *is unordered.*

(iii) $C = \{p \in X\colon\ \|T^n x - p\|/\kappa^n \to 0\} = \{x \in X\colon\ \|T^n x - p\|/\kappa^n$ *is bounded*$\}$, *for any* κ, $\tau < \kappa < \rho$. *In particular,* $C \subset K$.

(iv) $K \setminus C = \{x \in K\colon\ \|T^n x - p\|/\kappa^n \to \infty\} = \{x \in K\colon\ \|T^n x - p\|/\kappa^n$ *is unbounded*$\}$, *for any* κ, $\tau < \kappa < \rho$.

(v) $K \setminus C = K \cap M$.

Conclusion (v) implies most orbits converging to p do so monotonically, but more can be said. Indeed, $K \cap M_+ = \{x \in K\colon\ (T^n x - p)/\|T^n x - p\| \to -v\}$ and a similar result for $K \cap M_-$ with v replacing $-v$ holds. The manifold C is a local version of the unordered invariant hypersurfaces obtained by Takáč in [209].

Corresponding to the space V_1 spanned by $v \gg 0$ for $T'(p)$, a locally forward invariant, one dimensional complement to the codimension one manifold C is given in the following result.

THEOREM 5.25. *There is* $\epsilon > 0$ *and a one-dimensional locally forward invariant* C^1 *manifold* $W \subset B(p; \epsilon)$, *tangent to* V *at* p. *If* $\rho > 1$, *then* W *is locally unique, and for each* $x \in W$ *there is a sequence* $\{x_{-n}\} \subset W$ *with* $Tx_{-n} = x_{-n+1}$, $x_0 = x$, *and* $\kappa^n \|x_{-n} - p\| \to 0$ *for any* κ, $1 < \kappa < \rho$.

Here $B(p; \epsilon)$ is the open ϵ-ball centered at p. Local forward invariance of W means that $x \in W$ and $Tx \in B(x; \epsilon)$ implies $Tx \in W$. Related results are obtained by Smith [184]. In summary, the above results assert that the dynamical behavior of the nonlinear map T behaves near p like that of its linearization $T'(p)$. Obviously, the above results can be applied at a periodic point p of period k by considering the map T^k which has all the required properties.

Mierczyński [139] uses the results above to classify the convergent orbits of T. Similar results are obtained by Takáč in [210].

It is instructive to consider the sort of stable bifurcations that can occur from a linearly stable fixed point, or a linearly stable periodic point, for a one parameter family of mappings satisfying the hypotheses of the previous results, as the parameter passes through a critical value at which $\rho = 1$. The fact that there is a simple positive dominant eigenvalue of $(T^k)'(p)$ ensures that period-doubling bifurcations from a stable fixed point or from a stable periodic point, as a consequence of a real eigenvalue passing through -1, cannot occur. In a similar way, a Neimark–Sacker [113] bifurcation to an invariant closed curve cannot occur from a stable fixed or periodic point. These sorts of bifurcations can occur from unstable fixed or periodic points but then they will “be born unstable.”

The generic orbit of a smooth strongly order preserving semiflow converges to fixed point but such a result fails to hold for discrete semigroups, i.e., for strongly order preserving mappings. Indeed, such mappings can have attracting periodic orbits of period exceeding one as we have seen. However, Tereščák [217], improving earlier joint work with Poláčik [164,165], and [65], has obtained the strongest result possible for strongly monotone, smooth, dissipative mappings.

THEOREM 5.26 (Tereščák, 1996). *Let $T : Y \to Y$ be a completely continuous, C^1, point dissipative map whose derivative is strongly positive at every point of the ordered Banach space Y having cone Y_+ with nonempty interior. Then there is a positive integer m and an open dense set $U \subset Y$ such that the omega limit set of every point of U is a periodic orbit with period at most m.*

The map P is *point dissipative* (see Hale [58]) provided there is a bounded set B with the property that for every $x \in X$, there is a positive integer $n_0 = n_0(x)$ such that $P^n x \in B$ for all $n \geqslant n_0$. We note that the hypothesis that $T'(x)$ is strongly positive implies that T is strongly monotone by Lemma 5.1.

5.6. *Monotone planar maps*

A remarkable convergence result for planar monotone maps was first obtained by de Mottoni and Schiaffino [42]. They focused on the period-map for the two-species, Lotka–Volterra competition system of ordinary differential equations with periodic coefficients. The full generality of their arguments was recognized and improved upon by Hale and Somolinos [60] and Smith [188,189,192]. We follow the treatment Smith in [192].

In addition to the usual order relations on $\mathbb{R}^2$, $\leqslant, <, \ll$, generated by $\mathbb{R}^2_+$, we have the "southeast ordering" ($\leqslant_K$), generated by the fourth quadrant $K = \{(u, v)\colon\ u \geqslant 0, v \leqslant 0\}$. The map T is *cooperative* if it is monotone relative to $\leqslant$ and *competitive* if it is monotone relative to K.

Throughout this subsection, we assume that $T : A \to A$ is a continuous competitive map on the subset A of the plane. Further hypotheses concerning A will be made below. As noted above, all of the results have obvious analogs in the case of cooperative planar maps (just interchange cones). Competitive planar maps preserve the order relation $\leqslant_K$ by definition, but they also put constraints on the usual ordering, as we show below.

LEMMA 5.27. *Let $T : A \to A$ be a competitive map on $A \subset \mathbb{R}^2$. If $x, y \in A$ satisfy $Tx \ll Ty$, then either $x \ll y$ or $y \ll x$.*

PROOF. If neither $x \ll y$ nor $y \ll x$ hold, then $x \leqslant_K y$ or $y \leqslant_K x$ holds. But $x \leqslant_K y$ implies $Tx \leqslant_K Ty$ which is incompatible with $Tx \ll Ty$. A similar contradiction is obtained from $y \leqslant_K x$. □

Lemma 5.27 suggests placing one of the following additional assumptions on T.

(O_+) If $x, y \in A$ and $Tx \ll Ty$, then $x \leqslant y$.
(O_-) If $x, y \in A$ and $Tx \ll Ty$, then $y \leqslant x$.

As we shall soon see, if T is orientation preserving, then (O_+) holds and if it is orientation reversing, then (O_-) holds. A sequence $\{x_n = (u_n, v_n)\} \subset \mathbb{R}^2$ is *eventually componentwise monotone* if there exists a positive integer N such that either $u_n \leqslant u_{n+1}$ for all $n \geqslant N$ or $u_{n+1} \leqslant u_n$ for all $n \geqslant N$ and similarly for v_n.

In the case of orientation-preserving maps, the following result was first proved by de Mottoni and Schiaffino [42] for the period map of a periodic competitive Lotka–Volterra system of differential equations.

THEOREM 5.28. *If T is a competitive map for which* (O_+) *holds then for all $x \in A$, $\{T^n x\}_{n \geqslant 0}$ is eventually component-wise monotone. If the orbit of x has compact closure in A, then it converges to a fixed point of T. If, instead,* (O_-) *holds then for all $x \in A$, $\{T^{2n} x\}_{n \geqslant 0}$ is eventually component-wise monotone. If the orbit of x has compact closure in A, then its omega limit set is either a period-two orbit or a fixed point.*

PROOF. We first note that if T is competitive and (O_-) holds then T^2 is competitive and (O_+) holds (use Lemma 5.27) so the second conclusion of the theorem follows from the first.

Suppose that (O_+) holds. If $T^n x \leqslant_K T^{n+1} x$ or $T^{n+1} x \leqslant_K T^n x$ holds for some $n \geqslant 1$, then it holds for all larger n so the conclusion is obvious. Therefore, we assume that this is not the case. It follows that for each $n \geqslant 1$ either (a) $T^n x \ll T^{n+1} x$ or (b) $T^{n+1} x \ll T^n x$. We claim that either (a) holds for all n or (b) holds for all n. Assume $x \ll Tx$ (the argument is similar in the other case). If the claim is false, then there is an $n \geqslant 1$ such that $x \ll Tx \ll \cdots \ll T^{n-1} x \ll T^n x$ but $T^{n+1} x \ll T^n x$. But (O_+) implies $T^n x \leqslant T^{n-1} x$ contradicting the displayed inequality. □

Orbits may not converge to a fixed point if (O_-) holds. Consider the map $T : I \to I$ where $I = [-1, 1]^2$ and $T(u, v) = (-v, -u)$ reflects points through the line $v = -u$. It is easy to see using Lemma 5.1 that T is competitive and that (O_-) holds (see below). Fixed points of T lie on the above-mentioned line but all other points in I are period-two points.

The hypotheses (O_+) and (O_-) on T are global in nature and therefore can be difficult to check in specific examples. We now give sufficient conditions for them to hold that may be easier to verify in applications. *A contains order intervals* if $x, y \in A$ and $x \ll y$ implies that $[x, y] \subset A$. Clearly, $A = [a, b]$ contains order intervals. If $A \subset \mathbb{R}^2$ and $T : A \to \mathbb{R}^2$, we say that T is C^1 if for each $a \in A$ there is an open set U in $\mathbb{R}^2$ and a continuously differentiable function $F : U \to \mathbb{R}^2$ that coincides with T on $U \cap A$. We will have occasion to make certain hypotheses concerning $T'(x)$ even though it is not necessarily uniquely defined. What we mean by this is that there exists an F as above such that $T'(x) = DF(x)$ has the desired properties. This abuse of language will lead to no logical difficulties in the arguments below. In the applications, A will typically be $\mathbb{R}^2_+$ or some order interval $[a, b]$ where $a \ll b$ in which case T' is uniquely defined.

Consider the following hypothesis:

(H_+) (a) A contains order intervals and is p-convex with respect to $\leqslant_K$.
(b) $\det T'(x) > 0$ for $x \in A$.

(c) $T'(x)(K) \subset K$ for $x \in A$.
(d) T is injective.

Hypothesis (H_-) is identical except the inequality is reversed in (b).

LEMMA 5.29. *If $T : A \to A$ satisfies* (H_+)*, then T is competitive and* (O_+) *holds. If* (H_-) *holds, then T is competitive and* (O_-) *holds.*

PROOF. T is competitive by hypothesis (c) since A is p-convex with respect to $\leqslant_K$. Assuming that (H_+) holds, $x, y, Tx, Ty \in A$ and $Tx \ll Ty$, we will show that $x \ll y$. According to Lemma 5.27, the only alternative to $x \ll y$ is $y \ll x$ so we assume the latter for contradiction. Let a and b be the northwest and southeast corners of the rectangle $[y, x] \subset A$ so that $a \ll_K b$ and $[y, x] = [a, b]_K$. Since T is competitive on A, $T([y, x]) \subset [Ta, Tb]_K$ and $Tx \ll Ty$ implies that $Ta \ll_K Tb$. Consider the oriented Jordan curve forming the boundary of $[y, x]$ starting at a and going horizontally to x, then going vertically down to b, horizontally back to y and vertically up to a. As T is injective on A, the image of this curve is an oriented Jordan curve. Monotonicity of T implies that the image curve is contained in $[Ta, Tb]_K$, begins at Ta and moves monotonically with respect to $\leqslant_K$ (southwest) through Tx and then monotonically to Tb before moving monotonically (decreasing or northwest) from Tb through Ty and on to Ta. (H_+)(b) implies that T is locally orientation preserving, so upon traversing the first half of the image curve from Ta to Ty to Tb, the curve must make a “right turn” at Tb before continuing on to Tx and to Ta. As the image curve cannot intersect itself, we see that $Tx \ll Ty$ cannot hold, a contradiction. □

In specific examples it is often difficult to check that T is injective. It automatically holds if A is compact and connected and there exists $z \in T(A)$ such that the set $T^{-1}(z)$ is a single point. This is because the cardinality of $T^{-1}(w)$ is finite and constant for $w \in T(A)$ by Chow and Hale [26, Lemma 2.3.4].

The following is an immediate corollary of Theorem 5.28 and Lemma 5.29.

COROLLARY 5.30. *If $T : A \to A$ satisfies* (H_+)*, then $\{T^n x\}$ is eventually component-wise monotone for every $x \in A$. In this case, if an orbit has compact closure in A, then it converges to a fixed point of T. If T satisfies* (H_-)*, then $\{T^{2n} x\}$ is eventually component-wise monotone for every $x \in A$. In this case, if an orbit has compact closure in A, then its omega limit set is either a fixed point or a period-two orbit.*

As an application of Corollary 5.30, we recall the celebrated results of de Mottoni and Schiaffino [42] for the periodic Lotka–Volterra system

$$\begin{aligned} x' &= x\bigl[r(t) - a(t)x - b(t)y\bigr], \\ y' &= y\bigl[s(t) - c(t)x - b(t)y\bigr], \end{aligned} \tag{5.4}$$

where r, s, a, b, c, d are periodic of period one and $a, b, c, d \geqslant 0$. The period map $T : \mathbb{R}^2_+ \to \mathbb{R}^2_+$, defined by (5.2) for (5.4), is strictly monotone relative to the fourth quadrant cone K by virtue of Theorem 3.5. Indeed, (5.4) is a competitive system relative to the cone $\mathbb{R}^2_+$ (the off-diagonal entries of the Jacobian $J = J(t, x, y)$ of the right-hand side are nonpositive), and every such system is monotone relative to K. Observe that $J + \alpha I$, for large enough $\alpha > 0$, has nonnegative diagonal entries so $(J + \alpha I)(u, v)^T \in K$ if $(u, v)^T \in K$ (i.e., $u \geqslant 0, v \leqslant 0$). T is strongly monotone relative to K in $\operatorname{Int} \mathbb{R}^2_+$ if $b, c > 0$ by Corollary 3.11. Because T is injective and orientation preserving by Liouville's theorem, (H_+) holds. Orbits are seen to be bounded by simple differential inequality arguments, e.g., applied to $x' \leqslant x[r(t) - a(t)x]$. Consequently, by Corollary 5.30, all orbits $O(T)$ converge to a fixed point; equivalently, every solution of (5.4) is asymptotic to a period-one solution.

System (5.4) is most interesting when each species can survive in the absence of its competitor, i.e. the time average of r and s are positive. In that case, aside from the trivial fixed point $E_0 := (0, 0)$, there are unique fixed points of type $E_1 := (e, 0)$ and $E_2 := (0, f)$. Of course, $e, f > 0$ give initial data corresponding to the unique nontrivial one-periodic solutions of the scalar equations: $x' = x[r(t) - a(t)x]$ and $y' = y[s(t) - d(t)y]$. The dynamics of the period map for these equations is described by alternative (iii) of Theorem 5.20.

It is shown by de Mottoni and Schiaffino that there is a monotone, relative to K, T-invariant curve joining E_1 to E_2 which is the global attractor for the dynamics of T in $\mathbb{R}^2_+ \setminus \{E_0\}$. This work has inspired a very large amount of work on competitive dynamics. See Hale and Somolinos [60], Smith [188,189], Hess and Lazer [64], Hsu et al. [83], Smith and Thieme [201], Wang and Jiang [230,231,229], Liang and Jiang [121], Zanolin [238].

6. Semilinear parabolic equations

The purpose of this section is to analyze the monotone dynamics in a broad class of second order, semilinear parabolic equations.

For basic theory and further information on many topics we refer the reader to books of Amann [11], Henry [62] Cholewa and Dlotko [25], Hess [63], Lunardi [124] and Martin [125], the papers of Amann [7–10], and the survey article of Poláčik [163].

Solution processes for semilinear parabolic problems have been obtained by many authors; see for example [3,8,38,62,63,124,125,134,147,163,194,174,208,246]. We briefly outline the general procedure, due to Henry, with important improvements by Mora and Lunardi.

To balance the sometimes conflicting goals of order, topology and dynamics, the domain of a solution process must be chosen carefully. We rely on results of Mora [147], refined by Lunardi [124], for solution processes in Banach subspaces $C^k_B(\overline{\Omega}) \subset C^k(\overline{\Omega})$, $k = 0, 1$ determined by the boundary operator B.

6.1. *Solution processes for abstract ODEs*

If Y and X are spaces such that Y is a subset of X and the inclusion map $Y \to X$ is continuous, we write $Y \hookrightarrow X$. When Y and X are ordered Banach space structures, this notation tacitly states that Y is a linear subspace of X and $Y_+ = Y \cap X_+$.

The domain and range of any map h are denoted by $\mathsf{D}(h)$ and $\mathsf{R}(h)$.

6.1.1. *Processes* Let Z be a topological space and set $\widehat{Z} := \{(t, t_0, z) \in \mathbb{R}_+ \times \mathbb{R}_+ \times Z\colon\ t \geqslant t_0\}$. A *process* in Z is a family $\Theta = \{\Theta_{t,t_0}\}_{0 \leqslant t_0 < t}$ of continuous maps

$$\Theta_{t,t_0}\colon D_{t,t_0} \to Z, \quad D_{t,t_0} \text{ open in } Z,$$

where the set $\{(t, t_0, z) \in \widehat{Z}\colon\ z \in D(t, t_0)\}$ is open in $\widehat{Z}$ containing $\{(t, t, z)\colon\ t \geqslant 0, z \in Z\}$, with the properties:

- the map $(t, t_0, z) \mapsto \Theta_{t,t_0}(z)$ is continuous from $\widehat{Z}$ to Z.
- the *cocycle identities* hold:

$$t \geqslant t_1 \geqslant t_0 \quad \Longrightarrow \quad \Theta_{t,t_1} \circ \Theta_{t_1,t_0} = \Theta_{t,t_0}, \quad \Theta_{t,t} = \text{identity map of } Z.$$

Equivalently: there is a local semiflow Λ on $\mathbb{R}_+ \times Z$ such that $\Lambda_t(t_0, u_0) = (t + t_0, \Theta_{t,t_0}(u_0))$. It follows that for each (t_0, z) there is a maximal $\tau := \tau(t_0, z) \in (t_0, \infty]$ such that $z \in D_{t,t_0}$ for all $t \in [t_0, \tau)$. The *trajectory* of (t_0, z) is the parametrized curve $[t_0, \tau) \to Z$, $t \mapsto \Theta_{t,t_0}(z)$, whose image is the *orbit* of (t_0, z). A subset $S \subset Z$ is *positively invariant* if it contains the orbit of every point in $\mathbb{R}_+ \times S$.

A trajectory is *global* if it is defined on $[t_0, \infty)$. The process is called global when all trajectories are global.

Let S be a space such that $S \hookrightarrow Z$. It may be that S is positively invariant under the process Θ, and the maps $\Theta_{t,t_0}\colon S \cap D(t, t_0) \to S$ are continuous respecting the topology on S and furthermore, the map $(t, t_0, s) \to \Theta_{t,t_0}s$ is continuous from $\widehat{S}$ to S. In this case these maps form the *induced process* Θ^S in S.

A process Θ in an ordered space is called (locally) monotone, SOP, Lipschitz, compact, and so forth, provided every map Θ_{t,t_0}, $t > t_0$ has the corresponding property.

6.1.2. *Solution processes* Let X be a Banach space. $\mathcal{A}$ denotes a linear operator (usually unbounded) in X with domain $\mathsf{D}(\mathcal{A}) \subset X$, that is *sectorial* in the following strong sense:

- $\mathcal{A}$ is a densely defined, closed operator generating an analytic semigroup $\{\mathrm{e}^{t\mathcal{A}}\}_{t \geqslant 0}$ in $L(X)$, and the resolvent operators $(\lambda I - \mathcal{A})^{-1} \in L(X)$ are compact for sufficiently large $\lambda \geqslant 0$.

The latter property ensures that $\mathrm{e}^{t\mathcal{A}}$ is compact for $t > 0$ [156, Theorem 2.3.3].

We make $\mathsf{D}(\mathcal{A})$ into a Banach space with the graph norm $\|x\|_{\mathsf{D}(\mathcal{A})} = \|x\| + \|\mathcal{A}x\|$, or any equivalent norm. Then $\mathcal{A}\colon \mathsf{D}(\mathcal{A}) \to X$ is bounded, and $\mathsf{D}(\mathcal{A}) \hookrightarrow X$.

For $0 \leqslant \alpha \leqslant 1$ we define the fractional power domain of $\mathcal{A}^\alpha$ to be $X^\alpha = X^\alpha(\mathcal{A}) := \mathsf{D}(\mathcal{A}^\alpha)$. Thus we have [62]

$$\mathsf{D}(\mathcal{A}) \hookrightarrow X^\alpha \hookrightarrow X, \qquad \overline{\mathsf{D}(\mathcal{A})} = X.$$

Let $F\colon [0, \infty) \times X^\alpha \to X$ be a continuous map that is *locally Lipschitz in the second variable*, i.e.:

- $F|[0, \tau] \times B(r)$ has Lipschitz constant $L(\tau, r)$ in the second variable whenever $[0, \tau] \subset [0, \infty)$ and $B(r)$ is the closed ball of radius r in X^α.

Locally Hölder in the first variable is defined analogously. We say F is C^1 *in the second variable* if $\partial_w F(t, w)$ is continuous.

The data $(X, \mathcal{A}, F)$ determine the abstract initial value problem

$$\begin{cases} u'(t) = \mathcal{A}u(t) + F(t, u(t)) \quad (t > t_0), \\ u(t_0) = u_0 \in X. \end{cases} \tag{6.1}$$

A continuous curve $u : [t_0, \tau) \to X$, $t_0 < \tau \leqslant \infty$ is a (classical) *solution through* (t_0, u_0) if $u(t) \in \mathsf{D}(\mathcal{A})$ for $t_0 < t < \tau$ and (6.1) holds. It is well known (e.g., Lunardi [124, 4.1.2]) that every solution is also a *mild solution*, i.e., it satisfies the integral equation

$$u(t) = \mathrm{e}^{(t-t_0)\mathcal{A}} u_0 + \int_{t_0}^{t} \mathrm{e}^{(t-s)\mathcal{A}} F\big(s, u(s)\big)\, \mathrm{d}s \quad (t_0 \leqslant t < \tau). \tag{6.2}$$

Moreover, every mild solution is a solution provided F is locally Hölder in t (Lunardi [124, Proposition 7.1.3]).

A classical or mild solution is *maximal* if it does not extend to a classical or mild solution on a larger interval in $[t_0, \infty)$; it is then referred to as a *trajectory* at (t_0, u_0), and its image is an *orbit*. When such a trajectory is unique it is denoted by $t \mapsto u(t, t_0, u_0)$. In this case the *escape time* of (t_0, u_0) is $\tau(t_0, u_0) := \tau$. If $\tau = \infty$ the trajectory is called *global*.

The following basic result means that Eq. (6.1) is well-posed in a strong sense, and that solutions enjoy considerable uniformity and compactness.

THEOREM 6.1. *Let* $(t_0, u_0) \in \mathbb{R}_+ \times X^\alpha$. *There is a unique mild trajectory at* (t_0, u_0), *and it is a classical trajectory provided* $F(t, u)$ *is locally Hölder in* t. *If* $t_0 < t_1 < \tau(t_0, u_0)$, *there is a neighborhood* U *of* x_0 *in* X^α *and* $M > 0$ *such that*

$$\|u(t, t_0, u_1) - u(t, t_0, u_2)\|_{X^\alpha} \leqslant M \|u_1 - u_2\|_{X^\alpha}, \quad u_1, u_2 \in U.$$

There exist $C > 0$, $t_0 < t_1 < \tau(t_0, u_0)$, *a bounded neighborhood* N *of* u_0 *in* X *and a continuous map*

$$\Psi : [t_0, t_1] \times N \to X, \qquad (t, v) \mapsto u(t, t_0, v),$$

where $u(t, t_0, v)$ *is a mild solution, such that the following hold. If* $s, t \in (t_0, t_1]$, $0 \leqslant \alpha < 1$ *and* $v, w \in N$:

(i) $\|\Psi(s, v) - \Psi(s, w)\| \leqslant C\|v - w\|$;

(ii) $\|\Psi(s, v) - \Psi(s, w)\|_{X^\alpha} \leqslant (s - t_0)^{-\alpha} C \|v - w\|$;

(iii) $\Psi([s, t_1] \times N)$ *is precompact in* X^α;

(iv) $u(\cdot, t_0, v) : (t_0, t] \to X^\alpha$ *and* $u(\cdot, t_0, v) : [t_0, t] \to X$ *are continuous*;

(v) *trajectories bounded in* X^α *are global.*

PROOF. Lunardi [124, Theorems 7.1.2, 7.1.3 and 7.1.10] proves the first assertion. Items (i), (ii) and (iv) follow from [124, Theorem 7.1.5], and (v) follows from Theorem 7.1.8 (see also Henry [62, 3.3.4]). Fix β with $\alpha < \beta < 1$. As N is bounded in X, $\Psi(s \times N)$ is bounded in X^β by (ii) (with α in (ii) replaced by β). Therefore $\Psi(s \times N)$ is precompact in X^α, and (iii) follows because Ψ defines a local semiflow on $\mathbb{R}_+ \times X^\alpha$. □

Equation (6.1) induces a *solution process* Θ in X, defined by $\Theta_{t,t_0}(u_0) := u(t, t_0, u_0)$. Its restriction to X^α defines an induced solution process on that space. When Eq. (6.1) is autonomous, i.e., $F(t, u) = F(u)$, this solution process boils down to a local semiflow Φ in X^α, defined by $\Phi_t(t_0, u_0) = u(t + t_0, t_0, u_0)$.

When $F(t, u)$ has period $\lambda > 0$ in t, the solution process is λ-*periodic*: $\Theta_{t,t_0} \equiv \Theta_{t+\lambda,\, t_0+\lambda}$. In this case Θ reduces to a local semiflow on $\mathbf{S}^1 \times X^\alpha$, the dynamics of which are largely determined by the Poincaré map $T := \Theta_{\lambda,0}$ which maps an open subset of X^α continuously into X^α.

Let S be a set and Z a Banach space. We use expressions such as "S is bounded in Z" or "$S \subset Z$ is bounded" to mean $S \subset Z$ and $\sup_{u \in S} \|u\|_Z < \infty$. Note that S may also be unbounded in other Banach spaces.

A map defined on a metric space is *compact* if every bounded set in its domain has precompact image. It is *locally compact* if every point of the domain has a neighborhood with precompact image.

A Banach space Y is *adapted* to the data $(X, \mathcal{A}, F)$ if the following two conditions hold:

$$X^\alpha \hookrightarrow Y \hookrightarrow X \tag{6.3}$$

and the map $(t, u_0) \mapsto \Theta_{t,t_0} u_0$ from $[t_0, \tau) \times D(t, t_0) \cap Y$ to Y is continuous. The solution process Θ determines the *induced solution process* Θ^Y in Y. The domain of Θ^Y_{t,t_0} is the open subset $D^Y(t, t_0) := D_{t,t_0} \cap Y$ of Y.

Rather than work with fractional power spaces, one can assume that $F : [0, \infty) \times K \to X$ where K is a suitable subset of X. The subset $K \subset X$ is *locally closed* in the Banach space X if for each $x \in K$ there exists $r > 0$ such that $\{y \in K\colon \|x - y\| \leqslant r\}$ is closed in X. Closed and open subsets K of X are locally closed. Note that the following result gives existence and uniqueness of mild solutions while at the same time giving positive invariance. It is a special case of Theorems VIII.2.1 and VIII.3.1 in Martin [125]. Assumptions on the semigroup $\mathrm{e}^{t\mathcal{A}}$ remain as above.

THEOREM 6.2. *Let K be a nonempty locally closed subset of a Banach space X and let $F : [0, \infty) \times K \to X$ be continuous and satisfy*: *For each $R > 0$ there are $L_R > 0$ and $\gamma \in (0, 1]$ such that for $x, y \in K$, $\|x\|, \|y\| \leqslant R$, $0 \leqslant s, t \leqslant R$*

$$\big\|F(t, x) - F(s, y)\big\| \leqslant L_R\big(|t - s|^\gamma + \|x - y\|\big). \tag{6.4}$$

Suppose also that:

(a) $\mathrm{e}^{t\mathcal{A}}(K) \subset K$ *for all $t \geqslant 0$, and*

(b) $\liminf_{h \searrow 0} \frac{1}{h} \operatorname{dist}(x + hF(t, x), K) = 0$ *for $(t, x) \in [0, \infty) \times K$.*

Then for each $(t_0, u_0) \in [0, \infty) \times K$, there is a unique classical trajectory $u(t, t_0, u_0)$ of (6.2) *defined on a maximal interval $[t_0, \tau)$, and $u(t) \in K$ for $t_0 \leqslant t < \tau$.*

This result is useful for parabolic systems when $X = C^k(\overline{\Omega})$, $k = 0, 1$ but not when $X = L^{\mathrm{p}}(\Omega)$. The substitution operators are well-behaved in the former cases but require very stringent growth conditions for the latter; see Martin [125]. By virtue of the uniqueness assertions of Theorem 6.1 and Theorem 6.2, the solution processes given by the two results agree on K if (6.4) holds.

Hypothesis (a) is obviously required for the positive invariance of K in case $F = 0$. Hypothesis (b), called the *subtangential condition,* is easily seen to be a necessary condition for the positive invariance of K if $\mathcal{A} = 0$. See Martin [125, Theorem VI.2.1]. Both hypotheses are trivially satisfied if $K = X$.

The following result is a special case of [125, Proposition VIII.4.1]:

PROPOSITION 6.3. *Let* $F : [0, \infty) \times X \to X$ *be continuous and satisfy* (6.4) *with* $K = X$ *and let* $u(t) = u(t, t_0, x_0)$ *be the unique classical trajectory defined on a maximal interval* $[t_0, \tau)$ *guaranteed by Theorem* 6.2. *If* $\tau < \infty$ *then* $\lim_{t\to\tau} \|u(t)\| = \infty$.

6.1.3. *Monotone processes* Given our interest in establishing monotonicity properties of solution processes induced by parabolic systems in various functions spaces, there are two approaches one may take. One is to establish the properties on spaces of smooth functions such as fractional power spaces X^α for $\alpha < 1$ near unity and then try to extend the monotonicity to larger spaces, e.g., $C^0(\overline{\Omega})$, by approximation. An alternative is to establish the monotonicity properties on the larger spaces first and then get corresponding properties on the smaller spaces by restriction. We give both approaches here, beginning with the former.

A process Θ is *very strongly order preserving* (= VSOP) if it is monotone and has the following property: Given $t_0 \geqslant 0$, $u > v$, and $\epsilon > 0$, there exist $s \in (t_0, t_0 + \epsilon]$ and neighborhoods U, V of u, v respectively such that

$$t \geqslant s \quad \Longrightarrow \quad \Theta_{t,t_0}(U \cap D_{t,t_0}) > \Theta_{t,t_0}(V \cap D_{t,t_0}).$$

This implies Θ is SOP and strictly monotone.

THEOREM 6.4. *Assume* X *is an ordered Banach space and* $Y \hookrightarrow X$ *an ordered Banach space such that* Y *is dense in* X *and the order cone* $Y_+ := Y \cap X_+$ *is dense in* X_+. *Let* Θ *be a process in* X *that induces a monotone process* Θ^Y *in* Y. *Then*:

(a) Θ *is monotone.*

(b) *Assume* $\mathsf{R}(\Theta_{t,t_0}) \subset Y$ *for all* $t > t_0 \geqslant 0$. *Then* Θ *is strictly monotone if* Θ^Y *is strictly monotone, and* Θ *is VSOP provided* Θ^Y *is strongly monotone and* $\Theta_{t,t_0} : D(t, t_0) \to Y$ *is continuous for* $t > t_0$.

PROOF. (a) Fix u and $v > u$ in X. The closed line segment $\overline{uv}$ spanned by u and v is compact, hence there exists $\rho > t_0$ with $\overline{uv} \subset D_{t_0,\rho}$. By the density assumptions there exist convergent sequences $u_n \to u$, $v_n \to v$ in $D_{t_0,\rho}$ such that $u_n, v_n \in Y$ and $u_n < v_n$. As Θ^Y is induced from Θ, it follows that $u_n, v_n \in D^Y_{t_0,\rho}$. For all $t \in [t_0, \rho)$,

$$\Theta_{t,t_0}(u_n) = \Theta^Y_{t,t_0}(u_n) \leqslant \Theta^Y_{t,t_0}(v_n) = \Theta_{t,t_0}(v_n).$$

Taking limits as $n \to \infty$ proves $\Theta_{t,t_0}(u) \leqslant \Theta_{t,t_0}(v)$. Thus Θ is monotone.

(b) Assume now that Θ^Y is strictly monotone. We show that Θ is strictly monotone. Let $u(t), v(t)$ be local trajectories with $u(t_0) < v(t_0)$. If $r \in (t_0, t_1]$ is sufficiently near t_0, then $u(r), v(r)$ are distinct points of Y, and $u(r) < v(r)$ by (a). Hence $u(t_1) < v(t_1)$ by strict monotonicity of Θ^Y.

To prove Θ is VSOP, let $u(t), v(t)$ be as above with $u(t_0), v(t_0) \in D_{t,t_0}$. If $t_0 < s < r < t$, strict monotonicity implies $u(s) > v(s)$. These points are in Y, Θ^Y is strongly monotone, and Θ agrees with Θ^Y in Y. Therefore there are disjoint neighborhoods $U_1, V_1 \subset Y$ of $u(s), v(s)$ respectively, such that

$$\Theta_{r,s}(U_1 \cap D_{r,s}) \gg \Theta_{r,s}(V_1 \cap D_{r,s})$$

and strict monotonicity implies that

$$t > r \quad \Longrightarrow \quad \Theta_{t,r}(U_1 \cap D_{t,r}) > \Theta_{t,r}(V_1 \cap D_{t,r}). \tag{6.5}$$

As $\Theta_{r,t_0} : D(r, t_0) \to Y$ is continuous, we may define neighborhoods $U, V \subset X$ of $u(t_0), v(t_0)$ respectively by

$$U = \Theta_{r,t_0}^{-1}(U_1), \qquad V = \Theta_{r,t_0}^{-1}(V_1).$$

By (6.5) and the cocycle identities,

$$t > r \quad \Longrightarrow \quad \Theta_{t,t_0}(U \cap D_{t,t_0}) > \Theta_{t,t_0}(V \cap D_{t,t_0}). \qquad \square$$

Let X be an ordered Banach space with positive cone X_+ and K a locally closed subset. The mapping $F : K \to X$ is said to be *quasimonotone* (relative to X_+) if:

(QM) For all $(t, x), (t, y) \in [0, \infty) \times K$ satisfying $x \leqslant y$ we have:

$$\lim_{h \searrow 0} \frac{1}{h} \operatorname{dist}\big(y - x + h\big[F(t, y) - F(t, x)\big], X_+\big) = 0.$$

The next result is due to [125, Proposition VIII.6.1 and Lemma 6.3] (see also [129] in case of abstract delay differential equations).

THEOREM 6.5. *Assume the hypotheses of Theorem* 6.2 *hold*, F *is quasimonotone*, *and* $e^{t\mathcal{A}}$ *is a positive operator for* $t \geqslant 0$. *In addition, suppose one of the following*:

(i) K *is open*.

(ii) $K + X_+ \subset K$.

(iii) X *is a Banach lattice and* $K = [u, v]$ *for some* $u, v \in X \cup \{-\infty, \infty\}$, $u \leqslant v$.

Then

$$x, y \in K, x \leqslant y \quad \Longrightarrow \quad u(t, x) \leqslant u(t, y) \quad \big(0 \leqslant t \leqslant \min\{\tau_x, \tau_y\}\big).$$

By $[-\infty, v]$, $v \in X$, is meant the set $\{x \in X\colon\ x \leqslant v\}$; similarly for other intervals involving $\pm\infty$. Of course, $-\infty \leqslant v \leqslant \infty$ for every $v \in X$. Observe that $K = [u, \infty]$ is covered by both (ii) and (iii).

REMARK 6.6. If F has the property that for each $x, y \in K$ with $x \leqslant y$, there exists $\lambda > 0$ such that $F(t,x) + \lambda x \leqslant F(t,y) + \lambda y$ then F is quasimonotone because

$$\begin{aligned} y - x + h\bigl[F(t,y) - F(t,x)\bigr] &= (1 - \lambda h)(y - x) \\ &\quad + h\bigl[F(t,y) + \lambda y - F(t,x) - \lambda x\bigr] \in X_+ \end{aligned}$$

when $h < \lambda^{-1}$.

REMARK 6.7. It is well-known that $\mathrm{e}^{t\mathcal{A}}$ is a positive operator if and only if $(\lambda I - \mathcal{A})^{-1}$ is a positive operator for all large positive λ. See, e.g., [11, Theorem II 6.4.1] or [125, Proposition 7.5.3]. Indeed, if K is a closed convex subset of X, then $\mathrm{e}^{t\mathcal{A}}K \subset K$ if and only if $(\lambda I - \mathcal{A})^{-1}K \subset K$ for all large positive λ.

A Banach space X is a *Banach lattice* if for each $x, y \in X$, $x \vee y := \sup\{x, y\}$ exists and the norm is monotone in the sense:

$$|x| \leqslant |y| \quad \Longrightarrow \quad \|x\| \leqslant \|y\|,$$

where $|x|$ denotes the absolute value of x: $|x| := (-x) \vee x$ (see Vulikh [225]). Banach lattices are easy to work with due to simple formulas such as

$$\operatorname{dist}(x, X_+) = \|x - x_+\| = \|x_-\|,$$

where $x_+ := x \vee 0$ and $x_- = -(-x)_+$. The requirement that X be a Banach lattice is a rather strong hypothesis which essentially restricts applicability to $X = L^p(\Omega), C^0(\overline{\Omega})$ or $C_0^0(\overline{\Omega})$. However, the latter two will be important for reaction–diffusion systems.

6.2. *Semilinear parabolic equations*

Let $\Omega \subset \mathbb{R}^n$ be the interior of a compact n-dimensional manifold with C^2 boundary $\partial\Omega$. We consider the semilinear system of m coupled equations ($1 \leqslant i \leqslant m$):

$$\begin{aligned} &\frac{\partial u_i}{\partial t} = (A_i u_i)(t,x) + f_i(t,x,u,\nabla u) && (x \in \Omega,\ t > t_0), \\ &(B_i u_i)(t,x) = 0 && (x \in \partial\Omega,\ t > t_0), \\ &u_i(t_0, x) = v_{0,i}(x) && (x \in \overline{\Omega}). \end{aligned} \tag{6.6}$$

Here the unknown function is $u = (u_1, \dots, u_m) : \overline{\Omega} \to \mathbb{R}^m$, and $\nabla u := (\nabla u_1, \dots, \nabla u_m) \in (\mathbb{R}^n)^m$ lists the spatial gradients ∇u_i of the u_i, i.e., $\nabla u_i := (\frac{\partial u_i}{\partial x_1}, \dots, \frac{\partial u_i}{\partial x_n})$. Each $A_i(x)$ is a second order, elliptic differential operator of the form

$$A_i(x) = \sum_{l,j=1}^{n} C_{lj}^{i}(x) \frac{\partial}{\partial x_l} \frac{\partial}{\partial x_j} + \sum_{j=1}^{n} b_j^i(x) \frac{\partial}{\partial x_j} \tag{6.7}$$

with uniformly continuous and bounded coefficients. Each $n \times n$ matrix $C^i(x) := [C^i_{lj}(x)]$ is assumed positive definite:

$$0 < \inf\bigl(\bigl\langle C^i(x)y, y\bigr\rangle\bigr) \quad \bigl(x \in \Omega, y \in \mathbb{R}^n, |y| = 1\bigr),$$

where $\langle\cdot,\cdot\rangle$ denotes the Euclidean inner product on $\mathbb{R}^n$.

The function

$$f := (f_1, \dots, f_m) : \mathbb{R}_+ \times \overline{\Omega} \times \mathbb{R}^m \times \bigl(\mathbb{R}^n\bigr)^m \to \mathbb{R}^m$$

is continuous, and $f(t, x, u, \xi)$ is locally Lipschitz in $(u, \xi) \in \mathbb{R}^m \times (\mathbb{R}^n)^m$.

Each boundary operator B_i acts on sufficiently smooth functions $v : [t_0, \tau) \times \overline{\Omega} \to \mathbb{R}$ in one of the following ways, where $x \in \partial\Omega$:

$$\begin{aligned}
&\textit{Dirichlet}: && (B_i v)(t, x) = v(t, x);\\
&\textit{Robin}: && (B_i v)(t, x) = \gamma_i v(t, x) + \frac{\partial v}{\partial \xi_i}(t, x);\\
&\textit{Neumann}: && (B_i v)(t, x) = \frac{\partial v}{\partial \xi_i}(t, x),
\end{aligned}$$

where $\gamma_i : \overline{\Omega} \to [0, \infty)$ is continuously differentiable, and $\xi_i : \overline{\Omega} \to \mathbb{R}^n$ is a continuously differentiable vector field transverse to $\partial\Omega$ and pointing outward from Ω. Note that Neumann is a special case of Robin.

We rewrite (6.6) as an initial-boundary value problem for an unknown vector-valued function $u := (u_1, \dots, u_m) : [t_0, \tau) \times \overline{\Omega} \to \mathbb{R}^m$,

$$\begin{aligned}
&\frac{\partial u}{\partial t} = (Au)(t, x) + f(t, x, u, \nabla u) && (x \in \Omega,\ t > t_0),\\
&(Bu)(t, x) = 0 && (x \in \partial\Omega,\ t > t_0),\\
&u(t_0, x) = u_0(x) && (x \in \overline{\Omega}),
\end{aligned} \tag{6.8}$$

where the operators $A := A_1 \times \cdots \times A_m$ and $B := B_1 \times \cdots \times B_m$ act componentwise on $u = (u_1, \dots, u_m)$. By a *solution process* for Eq. (6.8) we mean a process in some function space on $\overline{\Omega}$, whose trajectories are solutions to (6.8).

Of special interest are *autonomous* systems, for which $f = f(x, u, \nabla u)$; and the *reaction–diffusion* systems, characterized by $f = f(t, x, u)$.

Assume $n < p < \infty$. To Eq. (6.8) we associate an abstract differential Eq. (6.1) in $L^p(\Omega, \mathbb{R}^m)$. The pair of operators (A_i, B_i) has a sectorial realization $\mathcal{A}_i$ in $L^p(\Omega)$ with domain $\mathcal{D}(\mathcal{A}_i) \hookrightarrow L^p(\Omega)$ (Lunardi [124, 3.1.3]). The operator $\mathcal{A} := \mathcal{A}_1 \times \cdots \times \mathcal{A}_m$ is sectorial on $X := L^p(\Omega, \mathbb{R}^m) = [L^p(\Omega)]^m$.

For $\alpha \in [0, 1)$ set $X^\alpha := X^\alpha(\mathcal{A})$. We choose α so that f defines a continuous *substitution operator*

$$F : \mathbb{R}_+ \times X^\alpha \to X, \qquad F(t, u)(x) := f\bigl(t, x, u(x), \nabla u(x)\bigr).$$

It suffices to take α

$$1 > \alpha > \frac{1}{2}\left(1 + \frac{n}{p}\right), \tag{6.9}$$

for then $X^\alpha \hookrightarrow C^1(\overline{\Omega}, \mathbb{R}^m)$ by the Sobolev embedding theorems.

The data $(\mathcal{A}, F)$ thus determine an abstract differential equation $u' = \mathcal{A}u + F(t, u)$ in X, whose trajectories $u(t)$ correspond to solutions $u(t, x) := u(t)(x)$ of (6.6). The assumptions on f make $F(t, u)$ locally Lipschitz in $u \in X^\alpha$.

By Theorem 6.1 and the Sobolev embedding theorem we have:

PROPOSITION 6.8. *Equation* (6.8) *defines a solution process* Θ *on* $X := L^p(\Omega, \mathbb{R}^m)$ *which induces a solution process in* X^β *for every* $\beta \in [0, 1)$ *with* $\beta \geqslant \alpha$.

We quote a useful condition for globality of a solution:

PROPOSITION 6.9. *Assume there are constants* $C > 0$ *and* $0 < \epsilon \leqslant 1$ *such that*

$$\big\| f(t, x, v, \xi)\big\| \leqslant C\big(1 + \|v\| + \|\xi\|^{2-\epsilon}\big) \quad \text{for all } (t, x, v, \xi) \in \mathbb{R}_+ \times \overline{\Omega} \times S \times \mathbb{R}^n. \tag{6.10}$$

If $u : [t_0, \tau) \to L^p(\Omega, \mathbb{R}^m)$ *is a trajectory such that*

$$\limsup_{t \to \tau-} \big\| u(t)\big\|_{L^p(\Omega, \mathbb{R}^m)} < \infty \tag{6.11}$$

then $\tau = \infty$.

PROOF. Follows from Amann [9, Theorem 5.3(i)], taking the constants of that result to be $m = k = p_0 = \gamma_0 = 1$, $\kappa = s_0 = 0$, $\gamma_1 = 2 - \epsilon$. □

Solutions $u : [t_0, \tau) \times \overline{\Omega} \to \mathbb{R}^m$ to (6.8) enjoy considerable smoothness. For example, if the data $\partial\Omega_i, f_i, A_i, B_i$ are smooth of class $C^{2+2\epsilon}$, $0 < 2\epsilon < 1$, then $u \in C^{1+\epsilon, 2+2\epsilon}([t_1, t_2] \times \overline{\Omega}, \mathbb{R}^m)$ for all $t_0 < t_1 < t_2 < \tau$ (Lunardi [124, 7.3.3(iii)]).

While useful for many purposes, solution processes in the spaces X^α suffer from the drawback that X^α and its norm are defined implicitly, leaving unclear the domains of solutions and the meaning of convergence, stability, density and similar topological terms. In addition, the topology of X^α might be unsuitable for a given application. To overcome these difficulties we could appeal to results of Colombo and Vespri [29], Lunardi [124] and Mora [147], establishing induced processes in Banach spaces of continuous, smooth or L^p functions; or we can apply Theorem 6.2. We now define these spaces.

For $r \in \mathbb{N}$ let $C^r(\overline{\Omega})$ denotes the usual Banach space of C^r functions on $\overline{\Omega}$. Set

$$C_0^r\big(\overline{\Omega}\big) := \big\{v \in C^r\big(\overline{\Omega}\big) \colon v|\partial\Omega = 0\big\}.$$

With γ, ξ as in a Robin boundary operator and $r \geqslant 1$, define

$$C^r_{\gamma,\xi}\big(\overline{\Omega}\big) := \left\{ v \in C^r\big(\overline{\Omega}\big) \colon \gamma(x)v(x) + \frac{\partial v}{\partial \xi}(x) = 0 \ (x \in \partial\Omega) \right\}.$$

It is not hard to show that:

- $C^0(\overline{\Omega})$, $C^1(\overline{\Omega})$ and $C^1_{\gamma,\xi}(\overline{\Omega})$ are strongly ordered, with $u \gg 0$ if and only if $u(x) > 0$ for all $x \in \overline{\Omega}$;
- $C^1_0(\overline{\Omega})$ is strongly ordered, with $u \gg 0$ if and only if $u(x) > 0$ for all $x \in \Omega$ and $\partial u/\partial \nu > 0$ where $\nu : \partial\Omega \to \mathbb{R}^n$ is the unit vector field inwardly normal to $\partial\Omega$;
- $C^0_0(\overline{\Omega})$ is not strongly ordered. Both $C^0_0(\overline{\Omega})$ and $C^0(\overline{\Omega})$ are Banach lattices.

In terms of the boundary operators B_i, for $k = 0, 1$ we define Banach spaces

$$C^k_{B_i}\big(\overline{\Omega}\big) := \begin{cases} C^k_0\big(\overline{\Omega}\big) & \text{if } B_i \text{ is Dirichlet,} \\ C^k_{\gamma,\xi}\big(\overline{\Omega}\big) & \text{if } B_i \text{ is Robin and } k = 1, \\ C^0\big(\overline{\Omega}\big) & \text{if } B_i \text{ is Robin and } k = 0. \end{cases}$$

Note that $C^1_{B_i}(\overline{\Omega})$ is strongly ordered, while $C^0_{B_i}(\overline{\Omega})$ is strongly ordered if and only if B_i is Robin; $C^0_{B_i}(\overline{\Omega})$ is a Banach lattice. The ordered Banach space

$$C^k_B\big(\overline{\Omega}, \mathbb{R}^m\big) := \Pi_i C^k_{B_i}\big(\overline{\Omega}\big),$$

with the product order cone, is strongly ordered if $k = 1$, or $k = 0$ and no B_i is Dirichlet. The order cone $L^p(\Omega, \mathbb{R}^m)_+$ is the subset of $L^p(\Omega, \mathbb{R}^m)$ comprising equivalence classes represented by functions $\Omega \to \mathbb{R}^m_+$. Note that $L^p(\Omega, \mathbb{R}^m)$ is normally ordered but not strongly ordered.

It is known that the pair of operators (A_i, B_i) has a sectorial realization $\mathcal{A}_i$ on $C^k(B_i)$ and therefore the product operator $\mathcal{A}$ is sectorial on $C^k_B(\overline{\Omega}, \mathbb{R}^m)$. See Corollary 3.1.24, Theorems 3.1.25, 3.1.26 in [124].

LEMMA 6.10. *For $X = L^p(\Omega, \mathbb{R}^m)$ or $C^k_B(\overline{\Omega}, \mathbb{R}^m)$, the analytic semigroup $\mathrm{e}^{t\mathcal{A}}$ is a positive operator for $t \geqslant 0$ with respect to the cone of componentwise nonnegative functions in X.*

PROOF. As noted in Remark 6.7, it suffices to show that $(\lambda I - \mathcal{A})^{-1}$ is positive for large $\lambda > 0$, or equivalently, that for each i and $f_i \geqslant 0$, the solution $g_i \in D(\mathcal{A}_i)$ of $f_i = \lambda g_i - \mathcal{A}_i g_i$ satisfies $g_i \geqslant 0$. The existence of g_i is not the issue but rather it's positivity. Thus it boils down to $\lambda g_i - A_i g_i \geqslant 0 \Longrightarrow g_i \geqslant 0$. But these follow from standard maximum principle arguments. See Lemma 3.1.4 in [155]. □

With $X = L^p(\Omega, \mathbb{R}^m)$ and $\mathcal{A}$ and α as above, we have a chain of continuous inclusions of ordered Banach spaces

$$\mathsf{D}(\mathcal{A}) \hookrightarrow X^\alpha \hookrightarrow C^1_B\big(\overline{\Omega}, \mathbb{R}^m\big) \hookrightarrow C^0_B\big(\overline{\Omega}, \mathbb{R}^m\big) \hookrightarrow L^p\big(\Omega, \mathbb{R}^m\big),$$

with a solution process in $L^p(\Omega, \mathbb{R}^m)$ and an induced solution process in X^α.

PROPOSITION 6.11. *Let Θ be the solution process in $L^p(\Omega, \mathbb{R}^m)$ for Eq.* (6.1) *with $n < p < \infty$.*

(a) *For all $t > t_0$, Θ_{t,t_0} maps D_{t,t_0} continuously into $C^1_B(\overline{\Omega}, \mathbb{R}^m)$.*
(b) *Θ induces a solution process Θ^1 in $C^1_B(\overline{\Omega}, \mathbb{R}^m)$.*
(c) *Θ induces a solution process Θ^0 in $C^0_B(\overline{\Omega}, \mathbb{R}^m)$ provided $f = f(t, x, u)$.*

PROOF. By uniqueness of solutions it suffices to establish induced solution processes in $C^1_B(\overline{\Omega}, \mathbb{R}^m) \hookrightarrow L^p(\Omega, \mathbb{R}^m)$, and in $C^0_B(\overline{\Omega}, \mathbb{R}^m) \hookrightarrow L^p(\Omega, \mathbb{R}^m)$ when $f = f(t, x, u)$. This is done in Lunardi [124, Proposition 7.3.3] for $m = 1$, and the general case is similar. Part (c) follows from Theorem 6.2. □

Henceforth Θ^k, $k \in \{0, 1\}$, denotes the process Θ^0 or Θ^1 as in Proposition 6.11.

6.2.1. *Dynamics in spaces X_Γ* For any set $\Gamma \subset \mathbb{R}^m$ and $k = 0, 1$ define

$$\begin{aligned} X^k_\Gamma &:= \{u \in C^k_B(\overline{\Omega}, \mathbb{R}^m) \colon u(\overline{\Omega}) \subset \Gamma\}, \\ X_\Gamma &:= \{u \in L^p(\Omega, \mathbb{R}^m) \colon u(\Omega) \subset \Gamma\}. \end{aligned} \tag{6.12}$$

A *rectangle* in $\mathbb{R}^m$ is a set of the form $J = J_1 \times \cdots \times J_m$ where each $J_i \subset \mathbb{R}$ is a nondegenerate closed interval. $\mathbb{R}^m$, $\mathbb{R}^m_+$ and closed order intervals $[a, b]$, $a \leqslant b$ are rectangles.

PROPOSITION 6.12. *Let $J := \Pi_{i=1}^m J_i$ be a rectangle in $\mathbb{R}^m$ such that either $0 \in J_i$ or B_i is Neumann, and the following hold for all $x \in \overline{\Omega}$, $u \in \partial J$:*

$$f_i(t, x, u, 0) \geqslant 0 \quad \text{if } u_i = \inf J_i, \qquad f_i(t, x, u, 0) \leqslant 0 \quad \text{if } u_i = \sup J_i. \tag{6.13}$$

Then:

(i) *In the reaction–diffusion case, X_J is positively invariant for Θ and X^k_J is positively invariant for Θ^k ($k = 0, 1$).*
(ii) *Suppose $k = m = 1$ and $J \subset \mathbb{R}$ is an interval. Then X_J is positively invariant for Θ and X^1_J is positively invariant for Θ^1.*

PROOF. For the reaction–diffusion case we sketch a proof that X^0_J is Θ^0-positively invariant using Theorem 6.2. The proof that X_J is Θ-positively invariant follows from this since $\Theta_{t,t_0}(u)$ is the L^p limit $\lim_k \Theta^0_{t,t_0}(u_k)$ where $u_k \in X^0_J$ approximates $u \in X_J$ in L^p and the facts: $\Theta^0 = \Theta$ on X^0_J, a dense subset of the closed subset X_J. In order to verify the subtangential condition for X^0_J, it suffices to verify the subtangential condition for J:

$$\liminf_{h \searrow 0} \frac{1}{h} \operatorname{dist}\bigl(u + hf(t, x, u), J\bigr) = 0 \tag{6.14}$$

for each $(t, x, u) \in [0, \infty) \times \overline{\Omega} \times J$ by Martin [125, Proposition IX.1.1]. But (6.14) is a necessary condition for J to be positively invariant for the ODE

$$v' = f(t, x, v),$$

where x is a parameter. See, e.g., [125, Theorem VI.2.1]. It is well-known and easy to prove that condition (6.13) implies the positive invariance of J for the ODE (see, e.g., Proposition 3.3, Smith and Waltman [203, Proposition B.7], or Walter [227, Chapter II, Section 12, Theorem II]). It follows that (6.14) holds. Therefore the subtangential condition for X_J^0 holds. Finally, we must verify that $\mathrm{e}^{t\mathcal{A}} X_J^0 \subset X_J^0$ or, equivalently, that $\mathrm{e}^{t\mathcal{A}_i} C_{B_i}^0(\overline{\Omega}, J_i) \subset C_{B_i}^0(\overline{\Omega}, J_i)$. This follows from Remark 6.7 and standard maximum principle arguments. It also follows from standard comparison principles for parabolic equations. See, e.g., Pao [155, Lemma 2.1] or Smith [194, Corollary 2.4].

The case $k = m = 1$ is a special case of [227, Chapter IV, Section 25, Theorem II, Section 31, Corollaries IV and V]. □

Consider the case that (6.6) is autonomous:

$$\begin{aligned} &\frac{\partial u_i}{\partial t} = A_i u_i + f_i(x, u, \nabla u) && (x \in \overline{\Omega},\ t > t_0), \\ &B_i u_i = 0 && (x \in \partial\Omega,\ t > t_0), \end{aligned} \tag{6.15}$$

$i = 1, \ldots, m$. The solution processes Θ, Θ^1, Θ^0 reduce to local semiflows.

We introduce a mild growth condition, trivially satisfied in the reaction–diffusion case:

$$\begin{aligned} &\text{For each } s > 0 \text{ there exists } C(s) > 0 \text{ such that} \\ &|v| \leqslant s \quad \Longrightarrow \quad \bigl|f(x, v, \xi)\bigr| \leqslant C(s)\bigl(1 + |\xi|^{2-\epsilon}\bigr). \end{aligned} \tag{6.16}$$

The following result gives sufficient conditions for solution processes in X_Γ to be global, and to admit compact global attractors:

PROPOSITION 6.13. *Assume system* (6.15) *satisfies* (6.16). *Let $\Gamma \subset \mathbb{R}^m$ be a nonempty compact set such that X_Γ is positively invariant for* (6.15). *Then*:

(a) *There are solution semiflows Φ, Φ^1 in X_Γ, X_Γ^1 respectively. Φ^1 is compact.*

(b) *Assume* (6.15) *is reaction–diffusion. Then there is also a solution semiflow Φ^0 in X_Γ^0. The semiflows Φ, Φ^0, Φ^1 are compact and order compact. There is a compact set $K \subset X_\Gamma^1$ which is the global attractor for all three semiflows.*

PROOF. (a) Let Γ lie in the open ball of radius $R > 0$ about the origin in $\mathbb{R}^m$ and let $h : \mathbb{R}^m \to \mathbb{R}^m$ be any smooth bounded function that agrees with the identity on the open ball of radius R. Define g by $g(x, v, \xi) = f(x, h(v), \xi)$. Every trajectory in X_Γ of (6.15) is also a trajectory of the analogous system in which f is replaced by g (compare Poláčik [163, pp. 842–843]). Nonlinearity g satisfies (6.16) with $C(s)$ constant so (6.10) holds. As

$$\limsup_{t \to \tau -} \bigl\| u(t) \bigr\|_{C^0(\overline{\Omega}, \mathbb{R}^m)} \leqslant R,$$

which implies (6.11), all trajectories are global by Proposition 6.9. Thus, the restrictions of Ψ, Ψ^1 in X and $C^1_B(\overline{\Omega}, \mathbb{R}^m)$ respectively to X_Γ and X^1_Γ define semiflows Φ and Φ^1. As Ψ^1 is compact by Hale [58], Theorem 4.2.2, Φ^1 is compact because X^1_Γ is closed in $C^1_B(\overline{\Omega}, \mathbb{R}^m)$.

(b) In the reaction–diffusion case a similar argument establishes a compact solution semiflow Φ^0 in X^0_Γ; and Φ^0 is order compact because order intervals in X^0_Γ are bounded. To prove Φ^0 order compact, let N be an order interval in X_Γ. For every $t = 2s > 0$, Φ_s maps N continuously into an order interval N' of X^0_Γ. Precompactness in X_Γ of $\Phi_t N$ follows from the precompactness in X^0_Γ of $\Phi^0_s N'$, already established, and the continuous inclusion $\Phi_t N = \Phi^0_s \circ \Phi_s N \subset \Phi^0_s N'$.

To prove order compactness of Φ^1, let $N_1 \subset X^1_\Gamma$ be an order interval. N_1 is contained in an order interval N_0 of X^0_Γ. Let C^k denote closure in X^k_Γ. For all $t > 0$ we have $\mathsf{C}^1(\Phi^1_t N_1) = \mathsf{C}^1(\Phi^0_t N_1) \subset \mathsf{C}^1\mathsf{C}^0(\Phi^0_t N_0)$, and the latter set is compact because Φ^0 is order compact. This proves $\Phi^1_t N_1$ is precompact in X^1_Γ.

X^0_Γ is closed and bounded in X^0, hence $\Phi^0_t X^0_\Gamma$ is precompact in X^0_Γ for all $t > 0$ by (a). Therefore $K := \bigcap_{t>0} \overline{\Phi^0_t X^0_\Gamma}$ is a compact global attractor for Φ^0. Similarly, K (with the same topology) is a compact global attractor for Φ.

We rely on the identity $\Phi^1_t = \Phi^0_t | X^1_\Gamma$ and continuity of $\Phi^0_t : X^0_\Gamma \to X^1_\Gamma$ for all $t > 0$. As K is invariant under Φ^0, it follows that K is a compact subset of X^1_Γ. To prove K a global attractor for Φ^1, it suffices to prove: For arbitrary sequences $\{x(i)\}$ in X^1_Γ, and $t(i) \to \infty$ in $\mathbb{R}_+$ with $t(i) > \epsilon > 0$, there is a sequence $i_k \to \infty$ in $\mathbb{N}$ such that $\{\Phi^1_{t(i_k)} x(i_k)\}$ converges in X^1_Γ to a point of K. Choose $\{i_k\}$ so that $\Phi^0_{t(i_k)-\epsilon}(i_k)$ converges X^0_Γ as $k \to \infty$ to $p \in K$; this is possible because K is a compact global attractor for Φ^0. Then $\Phi^1_{t(i_k)} x(i_k) = \Phi^0_\epsilon \circ \Phi^0_{t(i_k)-\epsilon} x(i_k)$, which converges in X^1_Γ as $k \to \infty$ to $\Phi^0_\epsilon p \in K$. □

EXAMPLE. Let the u_i denote the concentrations or densities of entities such as chemicals or species. Such quantities are inherently positive, so taking the state space to be $L^p(\Omega, \mathbb{R}^m_+)$ or $C^k_B(\overline{\Omega}, \mathbb{R}^m_+)$ is appropriate. We make the plausible assumption that sufficiently high density levels must decrease. Modeling this situation by (a) and (b) below, we get the following result.

PROPOSITION 6.14. *In Eq.* (6.15) *assume* $f = f(x, u)$ *and let the following hold for* $i = 1, \ldots, m$:

(a) $f_i(x, u) \geqslant 0$ *if* $u_i = 0$;

(b) *there exists* $\kappa > 0$ *such that* $f_i(x, u) < 0$ *if* $u_i \geqslant \kappa$.

Then for $k = 0, 1$ *solution processes in the order cones* $L^p(\Omega, \mathbb{R}^m_+)$, $C^k_B(\overline{\Omega}, \mathbb{R}^m_+)$ *are defined by semiflows* Φ, Φ^k *respectively*; *and there is a compact set* $K \subset X^k_{[0,\kappa]^m}$ *that is the global attractor for* Φ, Φ^0 *and* Φ^1.

PROOF. Proposition 6.12 and (a) proves $L^p(\Omega, \mathbb{R}^m_+)$ and $C^k_B(\overline{\Omega}, \mathbb{R}^m_+)$ are positively invariant under the solution process.

Consider the compact rectangles $J(c) := [0, c\kappa]^m \subset \mathbb{R}^m$, $c \geqslant 1$. Assumption (b) and Proposition 6.12 entail positive invariance of $X_{J(c)}$. Proposition 6.13 shows that there are solution semiflows in $X_{J(c)}$ and $X^k_{J(c)}$ having a compact global attractor $K_c \subset X^1_{J(c)}$ in common. As the $J(c)$ are nested and exhaust $\mathbb{R}^m_+$, these semiflows come from solution semiflows Φ, Φ^k as required. Moreover, all the attractors K_c coincide with the compact set $K := K_1 \subset X^1_{J(1)}$. It is easy to see that K is the required global attractor. □

Results on global solutions and positively invariant sets can be found in many places. See for example Amann [9,10], Cholewa and Dlotko [25], Cosner [33], Lunardi [124], Poláčik [163], Smith [194], Smoller [205].

6.2.2. *Monotone solution processes for parabolic equations* We restrict attention here to monotonicity properties with respect to the standard point-wise and component-wise ordering of functions $\Omega \to \mathbb{R}^m$: $f \leqslant g$ if and only if $f_i(x) \leqslant g_i(x)$ for all x and all i. The natural ordering on $L^p(\Omega, \mathbb{R}^m)$ is defined on equivalence classes by the condition on representatives that $f_i(x) \leqslant g_i(x)$ almost everywhere.

Orderings induced by orthants in $\mathbb{R}^n$ other than the positive orthant can be handled easily by change of variables. See Mincheva [144] and [145] for results in the case of polyhedral cones in $\mathbb{R}^n$.

Consider the case $m = 1$ in Eq. (6.8).

THEOREM 6.15. *In Eq.* (6.8), *assume $m = 1$ and f is C^1. Then*:

(i) *Θ is VSOP on $L^p(\Omega, \mathbb{R}^m)$.*

(ii) *Θ^1 is strongly monotone in $C^1_B(\overline{\Omega})$.*

(iii) *If $f = f(t, x, u)$ the induced process Θ^0 on $C^0_B(\overline{\Omega})$ is VSOP, and strongly monotone if all boundary operators are Robin.*

PROOF. Let $u, v : [t_0, t_1] \times \overline{\Omega} \to \mathbb{R}$ be solutions with $v(t_0, x) - u(t_0, x) \geqslant 0$ for all x and > 0 for some x. Then $w := v - u$ is the solution to the problem

$$\begin{aligned}
&\frac{\partial w}{\partial t} = Aw + \sum_{j=1}^{n} b_j \frac{\partial w}{\partial x_j} + cw \quad && (x \in \overline{\Omega},\ t > t_0),\\
&Bw(t, x) = 0 && (x \in \partial\Omega,\ t > t_0),\\
&w(t_0, x) \geqslant 0, \quad w(t_0, x) \not\equiv 0 && (x \in \overline{\Omega})
\end{aligned} \tag{6.17}$$

where $b_j = b_j(t, x)$ and $c_j = c_j(t, x)$ are obtained as follows. Evaluate u, v and their spatial gradients at (t, x), and for $s \in [0, 1]$ set

$$Z(s) = (1 - s)(t, x, u, \nabla u) + s(t, x, v, \nabla v),$$

$$b(t, x) = \big(b_1(t, x), \ldots, b_n(t, x)\big) = \int_0^1 D_4 f\big(Z(s)\big)\,\mathrm{d}s,$$

$$c(t, x) = \int_0^1 D_3 f\big(Z(s)\big)\,\mathrm{d}s$$

where $D_4 f$ and $D_3 f$ denote respectively the derivatives of $f(t,x,y,\xi)$ with respect to $\xi \in \mathbb{R}^n$ and $y \in \mathbb{R}$. By Taylor's theorem

$$f(t,x,v,\nabla v) - f(t,x,u,\nabla u) = b(t,x)(\nabla u - \nabla v) + c(t,x)(u-v),$$

whence (6.17) follows.

The parabolic maximum principle and boundary point lemma ([194, Theorems 7.2.1, 7.2.2]) imply that the function $w(t_1,\cdot)$, considered as an element of $C^1_B(\overline{\Omega})$, is $\gg 0$. This proves (ii), and the first assertion of (iii) follows from Theorem 6.4(b). The proof of strong monotonicity for Robin boundary conditions is similar to the arguments given above. Part (i) follows from strong monotonicity of Θ^1, Theorem 6.4 and continuity of $\Theta_{t,t_0} : L^p(\Omega,\mathbb{R}^m) \to X^\alpha \hookrightarrow C^1_B(\overline{\Omega},\mathbb{R}^m)$. □

For $m \geqslant 2$ we impose further conditions on system (6.6) in order to have a monotone solution process: it must be of reaction–diffusion type, and the vector fields $f(t,x,\cdot)$ on $\mathbb{R}^m$ must be *cooperative*. In other words, $f(t,x,u)$ is C^1 in u and $\partial f_i/\partial u_j \geqslant 0$ for all $i \neq j$. (The latter condition holds vacuously if $m = 1$). When this holds then the system is called cooperative. If in addition, there exists $\bar{x} \in \Omega$ such that the $m \times m$ Jacobian matrix $[\partial f_i/\partial u_j(t,\bar{x},u)]$ is irreducible for all (t,u), we call the system *cooperative and irreducible*

THEOREM 6.16. *If system* (6.15) *is cooperative, then* Θ, Θ^k, $k = 0,1$ *are monotone. If the system is also irreducible, then*:

(i) *Θ is VSOP on $L^p(\Omega,\mathbb{R}^m)$.*
(ii) *Θ^1 is strongly monotone in $C^1_B(\overline{\Omega},\mathbb{R}^m)$.*
(iii) *Θ^0 is VSOP in $C^0_B(\overline{\Omega},\mathbb{R}^m)$ and is strongly monotone when all boundary operators are Robin.*

PROOF. Monotonicity in $C^0_B(\overline{\Omega},\mathbb{R}^m)$ follows directly from Theorem 6.5 and Remark 6.6. Indeed, let $u \leqslant v$ in $C^0_B(\overline{\Omega},\mathbb{R}^m)$ and t be fixed. Then

$$\begin{aligned}&\big[F(t,v) - F(t,u) + \lambda(v-u)\big](x)\\ &\quad = \int_0^1 \left(\frac{\partial f}{\partial u}\big(t,x,su(x)+(1-s)v(x)\big) + \lambda I\right) \mathrm{d}s\,(v-u)(x) \geqslant 0\end{aligned}$$

for some $\lambda > 0$ and all $x \in \overline{\Omega}$ by cooperativity of f and compactness of $\overline{\Omega}$. This implies that (QM) holds. The positivity of $\mathrm{e}^{t\mathcal{A}}$ follows from Lemma 6.10. Monotonicity of Θ in $L^p(\Omega,\mathbb{R}^m)$ follows from monotonicity of Θ^0 and Theorem 6.4.

The proof of VSOP and strong monotonicity for Robin boundary conditions in $C^0_B(\overline{\Omega},\mathbb{R}^m)$ is like that of Theorem 6.15(i), exploiting the maximum principle for weakly coupled parabolic systems (Protter and Weinberger [166, Chapter 3, Theorems 13, 14, 15 and pp. 192, Remark (i)]). See Smith [194, Section 7.4] for a similar proof.

Monotonicity of Θ^1 follows from monotonicity of Θ^0. Strong monotonicity of Θ^1, in the case of Dirichlet boundary conditions, requires exploiting the maximum principle as in the previous case (the same references apply). VSOP of Θ follows from strong monotonicity of Θ^1, Theorem 6.4 and continuity of the composition $\Theta_{t,t_0} : L^p(\Omega, \mathbb{R}^m) \to X^\alpha \to C^1_B(\overline{\Omega}, \mathbb{R}^m)$. □

6.3. *Parabolic systems with monotone dynamics*

We now treat autonomous systems (6.15) having monotone dynamics. Our goal is Theorem 6.17, a sample of the convergence and stability results derivable from the general theory.

In addition to the assumptions for (6.6), we require the following conditions to hold for the solution process Θ in $X := L^p(\Omega, \mathbb{R}^m)$, with p satisfying (6.9) and X^k_Γ defined in (6.12):

(SP) If $m \geqslant 2$ in system (6.15) then $f = f(x,u)$ and the system is cooperative and irreducible. $\Gamma \subset \mathbb{R}^m$ is a nonempty set, either an open set or the closure of an open set. The solution process induces semiflows Φ, Φ^1 in X_Γ, X^1_Γ respectively, and Φ^0 in X^0_Γ for the reaction–diffusion case. These semiflows are assumed to have compact orbit closures.

Simple conditions implying (SP) can be derived from Propositions 6.13.

The following statements follow from (SP), assertions about Φ^0 having the implied hypothesis $f = f(x,u)$:

- X^1_Γ is dense in X^0_Γ and in X_Γ.
- Φ and Φ^0 agree on X^0_Γ, and Φ, Φ^0 and Φ^1 agree on X^1_Γ.
- Φ_t (respectively, Φ^0_t) maps X_Γ (respectively, X^0_Γ) continuously into X^1_Γ for $t > 0$ (Proposition 6.11).
- Φ, Φ^1 and Φ^0 have the same omega limit sets, compact attractors and equilibria.
- If Γ is open or order convex and $f(x,u,\xi)$ is C^1 in (u,ξ), the Improved Limit Set Dichotomy (ILSD) holds for Φ^1 by Theorem 2.16, and for Φ and Φ^0 by Proposition 2.21.
- If Γ is compact then Φ^1 is compact. In the reaction–diffusion case with Γ compact, Φ, Φ^1 and Φ^0 are compact and order compact, and a common compact global attractor (Propositions 6.13).
- Φ^1 is strongly monotone; Φ^0 is VSOP, and strongly monotone if all boundary operators are Robin; Φ is VSOP (Theorem 6.16).

The sets of quasiconvergent, convergent and stable points for any semiflow Ψ are denoted respectively by $Q(\Psi), C(\Psi), S(\Psi)$. References to intrinsic or extrinsic topology of these sets (e.g., closure, density) for Φ, Φ^1 or Φ^0 are to be interpreted in terms of the topology of the corresponding domain X_Γ, X^1_Γ or X^0_Γ.

THEOREM 6.17. *If system* (6.15) *satisfies hypothesis* (SP), *then*:

(i) *The sets $Q(\Phi)$, $Q(\Phi^0)$ and $Q(\Phi^1)$ are residual.*

(ii) *Assume Γ is open or order convex and $f(x,u,\xi)$ is C^1 in (u,ξ). Then the sets $C(\Phi) \cap S(\Phi)$, $C(\Phi^0) \cap S(\Phi^0)$ and $C(\Phi^1)$ have dense interiors.*

(iii) *Assume $f = f(x, u)$ and Γ is compact. Then the semiflows Φ, Φ^0, Φ^1 are compact and order compact, and they have a compact global attractor in common.*

(iv) *Assume Γ is open or order convex and E_Γ is compact. Then some $p \in E_\Gamma$ is stable for Φ. Every such p is also stable for Φ^1, and for Φ^0 in the reaction–diffusion case. When E_Γ is finite, the same holds for asymptotically stable equilibria.*

PROOF. (i) follows from Theorem 1.21.

(ii) for Φ and Φ^0 follows from Theorem 2.25(b). For Φ^1, (ii) follows from Theorem 2.26(a).

(iii) is a special case of Proposition 6.13(b).

In (iv), to find a $p \in E_\Gamma$ having the asserted stability properties for Φ, it suffices to verify the hypotheses of Theorem 1.30: (a) follows from (i), while (b) and (c) holds by the assumptions on Γ and compactness of E. Similarly for Φ^0 in the reaction–diffusion case.

To prove the stability properties for p under Φ^1, it suffices by Theorem 1.31 to show that p has a neighborhood in X^1_Γ that is attracted to a compact set. By (i) and the assumptions on Γ, there are sequences $\{u_k\}$, $\{v_k\}$ in $Q(\Phi^1)$ converging to p in X_Γ, such that

$$u_k \leqslant u_{k+1} \leqslant p \leqslant v_{k+1} \leqslant v_k$$

and

$$p \neq \inf X_\Gamma \quad \Longrightarrow \quad u_k < u_{k+1} < p, \qquad p \neq \sup X_\Gamma \quad \Longrightarrow \quad p < v_{k+1} < v_k.$$

Replacing u_k, v_k by their images under Φ_{ϵ_k} for sufficiently small $\epsilon_k > 0$, we see from strong monotonicity of Φ^1 that we can assume:

$$p \neq \inf X_\Gamma \quad \Longrightarrow \quad u_k \ll u_{k+1} \ll p, \qquad p \neq \sup X_\Gamma \quad \Longrightarrow \quad p \ll v_{k+1} \ll v_k.$$

The sets $N_k := [[u_k, v_k]]_X \cap X_\Gamma$ are positively invariant and form a neighborhood basis at p in X_Γ.

Fix k_0 such that N_k is bounded in X^1_Γ for all $k \geqslant k_0$. By Theorem 6.1(iii), for every $s > 0$ there exists $j \geqslant k_0$ such that $\Phi_s(N_j)$ is precompact in X^α, hence in X^1_Γ. Fix such numbers s and j and let P denote the closure of $\Phi_s(N_j)$ in X^1_Γ. Being compact and positively invariant, P contains the compact global attractor $K := \bigcap_{t>0} \overline{\Phi_t P}$ for the semiflow in $\Phi^1|P$. Then N_j is a neighborhood p in X^1_Γ that is attracted under Φ^1 to K. □

Abstract

This chapter analyzes the dynamics of the positive solutions of a general class of planar periodic systems including those of Lotka–Volterra type and a more general class of models simulating symbiotic interactions within global competitive environments. It seems this is the first occasion where this problematic has been addressed within the context of periodic planar systems. Most of our mathematical analysis is focused towards the study of the existence of coexistence states and the problem of ascertaining the structure, multiplicity and stability of these coexistence states in purely symbiotic, and competitive, environments.

Keywords: Lotka–Volterra systems, symbiosis in competitive environments, coexistence states.

MSC: 34A34, 34C12, 92B05.

1. Introduction

Throughout this chapter, for any $T > 0$ we denote by $\mathcal{C}_T$ the Banach space of real T-periodic continuous functions endowed with the norm

$$\|u\|_{\mathcal{C}_T} := \max_{t\in\mathbb{R}} |u(t)| = \max_{t\in[0,T]} |u(t)|.$$

Similarly, $\mathcal{C}^1_T$ stands for the Banach space of real T-periodic functions of class $\mathcal{C}^1$ endowed with the norm

$$\|u\|_{\mathcal{C}^1_T} := \|u\|_{\mathcal{C}_T} + \|u'\|_{\mathcal{C}_T},$$

where $' = \frac{\mathrm{d}}{\mathrm{d}t}$. The Banach space $\mathcal{C}_T$ is ordered by its cone of non-negative functions

$$P := \{u \in \mathcal{C}_T\colon\ u(t) \geqslant 0,\ t \in \mathbb{R}\}.$$

Note that

$$\operatorname{Int} P = \{u \in \mathcal{C}_T\colon\ u(t) > 0,\ t \in \mathbb{R}\}.$$

Given $u, v \in \mathcal{C}_T$, we shall write $u \geqslant v$ if $u - v \in P$, $u > v$ if $u - v \in P \setminus \{0\}$, and $u \gg v$ if $u - v \in \operatorname{Int} P$.

The main goal of this chapter is analyzing the dynamics of

$$\begin{cases} u'(t) = \lambda\,\ell(t)u(t) - a(t)u^2(t) - b(t)u(t)v(t), \\ v'(t) = \mu\,m(t)v(t) - d(t)v^2(t) - c(t)u(t)v(t), \\ u(0) = x > 0, \quad v(0) = y > 0, \end{cases} \tag{1.1}$$

and, in particular, the existence, attractiveness and multiplicity of the component-wise non-negative T-periodic solutions of

$$\begin{cases} u'(t) = \lambda\ell(t)u(t) - a(t)u^2(t) - b(t)u(t)v(t), \\ v'(t) = \mu m(t)v(t) - d(t)v^2(t) - c(t)u(t)v(t), \end{cases} \tag{1.2}$$

where $\{\ell, m, a, b, c, d\} \subset \mathcal{C}_T$ satisfy

$$\ell > 0, \quad m > 0, \quad a > 0, \quad d > 0, \tag{1.3}$$

and $(\lambda, \mu) \in \mathbb{R}^2$ are regarded as two real parameters. System (1.2) exhibits three different types of non-negative T-periodic solution pairs. Namely, the *trivial state* $(0, 0)$, the *semi-trivial positive states* $(u, 0)$ and $(0, v)$ with $u \gg 0$ and $v \gg 0$, and the *coexistence states*, which are the solution pairs $(u, v) \in \mathcal{C}^1_T \times \mathcal{C}^1_T$ with $u \gg 0$ and $v \gg 0$. The interest of analyzing these states coming from the fact that in many circumstances they govern the dynamics of (1.1).

It should be noted that we are not imposing any sign restriction on the coupling coefficient functions $b(t)$ and $c(t)$. Thus, (1.2) is far from falling within the classical family of Lotka–Volterra periodic systems, since b and c might not have a constant sign. Actually, if given $h \in \mathcal{C}_T$ we denote

$$h^+ := \max\{h, 0\}, \quad h^- := h^+ - h, \quad I_+^h := \operatorname{Int}\operatorname{supp} h^+, \quad I_-^h := \operatorname{Int}\operatorname{supp} h^-,$$

and

$$I_0^h := \operatorname{Int} h^{-1}(0) = \mathbb{R} \setminus \big(\bar{I}_+^h \cup \bar{I}_-^h\big),$$

then, the species u and v interact according to the following patterns:

- u and v compete if $t \in I_+^b \cap I_+^c$—periods of time where $b(t) > 0$ and $c(t) > 0$.
- u and v cooperate if $t \in I_-^b \cap I_-^c$—periods of time where $b(t) < 0$ and $c(t) < 0$.
- u preys on v if $t \in I_-^b \cap I_+^c$, and v preys on u if $t \in I_+^b \cap I_-^c$—periods of time where $b(t)c(t) < 0$.
- u is free from the action of v if $t \in I_0^b$, and v is free from the action of u if $t \in I_0^c$—periods of time where $b(t)c(t) = 0$.

Consequently, within our general setting (1.1) allows all different types of interactions between the species u and v as time passes by.

Due to (1.3), we have that $\int_0^T a > 0$ and $\int_0^T d > 0$, and, hence, the change of variable

$$u := \frac{T}{\int_0^T a} U, \quad v := \frac{T}{\int_0^T d} V, \quad \Lambda := \frac{\lambda}{T} \int_0^T \ell, \quad M := \frac{\mu}{T} \int_0^T m,$$

transforms (1.2) into

$$\begin{cases} U'(t) = \Lambda \dfrac{\ell(t)}{\frac{1}{T}\int_0^T \ell} U(t) - \dfrac{a(t)}{\frac{1}{T}\int_0^T a} U^2(t) - \dfrac{b(t)}{\frac{1}{T}\int_0^T d} U(t)V(t), \\ V'(t) = M \dfrac{m(t)}{\frac{1}{T}\int_0^T m} V(t) - \dfrac{d(t)}{\frac{1}{T}\int_0^T d} V^2(t) - \dfrac{c(t)}{\frac{1}{T}\int_0^T a} U(t)V(t). \end{cases}$$

Consequently, without lost of generality, we will throughout assume that the following conditions are satisfied:

$$\frac{1}{T}\int_0^T \ell = \frac{1}{T}\int_0^T m = \frac{1}{T}\int_0^T a = \frac{1}{T}\int_0^T d = 1. \tag{1.4}$$

Therefore,

$$h = 1 \quad \text{if } h \in \{\ell, m, a, d\} \text{ is assumed to be constant.} \tag{1.5}$$

Throughout this chapter, given any function $h \in \mathcal{C}_T$ we shall denote

$$\hat{h} := \frac{1}{T}\int_0^T h(t)\,\mathrm{d}t, \qquad h_M := \max_{\mathbb{R}} h, \qquad h_L := \min_{\mathbb{R}} h. \tag{1.6}$$

Using these notations, conditions (1.3) and (1.4) can be summarized as follows:

$$\{\ell, m, a, d\} \subset P \setminus \{0\}, \qquad \hat{\ell} = \hat{m} = \hat{a} = \hat{d} = 1. \tag{1.7}$$

This work is distributed as follows. In Section 2 we provide some basic preliminaries needed for the subsequent mathematical analysis. Basically, it collects some well known results for the single logistic equation. Section 3 ascertains the linearized stability character of the semi-trivial positive solutions of (1.2).

Section 4 analyzes the minimal complexity of the components of the (λ, μ)-plane determined by the curves of neutral stability of the semi-trivial states. Several different situation cases will be differentiated, according to the nature of the interactions between the species u and v. The mathematical analysis carried out in Section 4 is reminiscent from J. Eilbeck and J. López-Gómez [12], where attention was exclusively focused into the competing species model.

In Section 5 we give an abstract unilateral global bifurcation result for systems. The main theorem of Section 5 is new in its full generality, and it admits a number of applications to the search of coexistence states in wide classes of nonlinear elliptic boundary value problems and planar periodic systems. Here, we will apply it to get all available existence results concerning the existence of coexistence states of (1.2). We point out that the abstract result of Section 5 does not follow as a direct application of the unilateral theory developed by P.H. Rabinowitz [31], but from the updated unilateral theorem of [19].

Section 6 considers the symbiotic prototype model ($b < 0$ and $c < 0$) and uses the theory of monotone periodic systems to show that the set of coexistence states linking the surfaces of the semi-trivial states along their respective curves of neutral stability is a real analytic surface, and that the stability character of the coexistence states changes as one crosses any *turning point* along that surface, while it remains unchanged when an hysteresis point is passed by. The theory developed here goes back to [17], within the context of quasi-cooperative systems, though here we are considerably tidying up the mathematical analysis of [17] and adding all necessary technical details that were omitted there in. Some of our abstract results for linear periodic systems provide with substantial improvements of some of the results of M.A. Krasnosel'skii [16]. Most precisely, the characterization of the attractive character of the system in terms of the existence of a strict positive supersolution seems to be a completely new result. This theorem is reminiscent of the characterization of the strong maximum principle for second order linear elliptic operators found by J. López-Gómez and M. Molina-Meyer [21,20]. Section 7 adapts the mathematical analysis of Section 6 to the competing species model ($b > 0$ and $c > 0$), which possesses a quasi-cooperative structure.

Finally, in Section 8 we briefly collect some of the main results available for predator prey models ($b > 0$ and $c < 0$, or $b < 0$ and $c > 0$). In a forthcoming chapter, we will adapt the theory developed by J. López-Gómez and M. Molina-Meyer [22,23], in order to discuss the effects of strategic symbiosis in competitive environments in order to show that strategic symbiosis allows the species to avoid extinction, while, simultaneously—and quite strikingly—the productivity of the ecosystem grows.

For historical remarks and a precise account of some of the most important works available about these models, the reader is sent to the expository chapter of J. Mawhin [27, 28], which bring an excellent complement to the mathematical analysis carried out in this chapter.

Throughout this chapter, given two real Banach spaces, X and Y, we denote by $\mathcal{L}(X;Y)$ the space of linear continuous operators between X and Y, and given $T \in \mathcal{L}(X;Y)$, $N[T]$, $R[T]$, and $\operatorname{spr} T$ will stand for the null space (kernel), the image (rank), and the spectral radius of T, respectively. The identity in X will be denoted by I_X, and, given $R > 0$ and $x \in X$, $B_R(x)$ will stand for the ball of radius R centered at x.

2. Basic preliminaries. The single logistic equation

In this section we focus our attention into the single logistic equation

$$w'(t) = \rho\alpha(t)w(t) - \beta(t)w^2(t), \tag{2.1}$$

where $\alpha, \beta \in \mathcal{C}_T$ satisfy

$$\hat{\alpha} > 0, \quad \beta > 0, \tag{2.2}$$

and $\rho \in \mathbb{R}$ is regarded as a real parameter. This equation provides us with the semi-trivial states—positive—of (1.2) when $(\alpha, \beta) \in \{(\ell, a), (m, d)\}$.

2.1. *The differential operator* $\frac{\mathrm{d}}{\mathrm{d}t} + V : \mathcal{C}^1_T \to \mathcal{C}_T$

We begin studying some useful properties of the differential operator

$$\frac{\mathrm{d}}{\mathrm{d}t} + V : \mathcal{C}^1_T \longrightarrow \mathcal{C}_T, \quad w \mapsto w' + Vw, \tag{2.3}$$

where $V \in \mathcal{C}_T$. The following result collects its main positivity properties.

PROPOSITION 2.1. *Suppose $V, f \in \mathcal{C}_T$ and consider the periodic problem*

$$w' + Vw = f, \quad w \in \mathcal{C}^1_T. \tag{2.4}$$

Then, the following assertions are true:

(a) (2.4) *has a unique solution for each $f \in \mathcal{C}_T$ if, and only if, $\int_0^T V \neq 0$. In such case, we denote by $\psi_{[V,f]}$ its unique solution.*

(b) *In case $\int_0^T V > 0$, $\psi_{[V,f]} \gg 0$ if $f > 0$, and $\psi_{[V,f]} \ll 0$ if $f < 0$.*

(c) *In case $\int_0^T V < 0$, $\psi_{[V,f]} \ll 0$ if $f > 0$, and $\psi_{[V,f]} \gg 0$ if $f < 0$.*

(d) *In case $\int_0^T V = 0$,* (2.4) *possesses a solution if, and only if,*

$$\int_0^T \mathrm{e}^{\int_0^s V} f(s)\,\mathrm{d}s = 0. \tag{2.5}$$

In particular, (2.4) *cannot admit a solution if either* $f > 0$ *or* $f < 0$. *Actually, under condition* (2.5) *any solution of*

$$w' + Vw = f$$

must be T*-periodic.*

PROOF. For any $w_0 \in \mathbb{R}$, the unique solution of the Cauchy problem

$$\begin{cases} w' + Vw = f, \\ w(0) = w_0, \end{cases}$$

is given by

$$w(t) = \mathrm{e}^{-\int_0^t V}\left[w_0 + \int_0^t \mathrm{e}^{\int_0^s V} f(s)\,\mathrm{d}s\right], \quad t \in \mathbb{R}, \tag{2.6}$$

and it is T-periodic if, and only if, $w(0) = w(T)$. Equivalently,

$$\big(\mathrm{e}^{\int_0^T V} - 1\big)w_0 = \int_0^T \mathrm{e}^{\int_0^s V} f(s)\,\mathrm{d}s. \tag{2.7}$$

Thus, in case $\int_0^T V \neq 0$,

$$w_0 := \frac{\int_0^T \mathrm{e}^{\int_0^s V} f(s)\,\mathrm{d}s}{\mathrm{e}^{\int_0^T V} - 1} \tag{2.8}$$

is the unique initial value to a T-periodic solution, while, if $\int_0^T V = 0$, then identity (2.7) implies (2.5).

As a result from this elementary analysis, substituting (2.8) into (2.6) and rearranging terms, we find that under assumption $\int_0^T V \neq 0$ the function

$$\begin{aligned}\psi_{[V,f]}(t) &:= \frac{\mathrm{e}^{-\int_0^t V}}{\mathrm{e}^{\int_0^T V} - 1}\left[\int_0^T \mathrm{e}^{\int_0^s V} f(s)\,\mathrm{d}s + \big(\mathrm{e}^{\int_0^T V} - 1\big)\int_0^t \mathrm{e}^{\int_0^s V} f(s)\,\mathrm{d}s\right] \\ &= \frac{\mathrm{e}^{-\int_0^t V}}{\mathrm{e}^{\int_0^T V} - 1}\left(\int_t^T \mathrm{e}^{\int_0^s V} f(s)\,\mathrm{d}s + \mathrm{e}^{\int_0^T V}\int_0^t \mathrm{e}^{\int_0^s V} f(s)\,\mathrm{d}s\right), \quad t \in \mathbb{R},\end{aligned}$$

provides us with the unique solution of (2.4). Note that, for any $V \in \mathcal{C}_T$, the auxiliary function

$$\Xi(t) := \int_t^T \mathrm{e}^{\int_0^s V} f(s)\,\mathrm{d}s + \mathrm{e}^{\int_0^T V}\int_0^t \mathrm{e}^{\int_0^s V} f(s)\,\mathrm{d}s, \quad t \in \mathbb{R}, \tag{2.9}$$

satisfies

$$\Xi \gg 0 \quad \text{if } f > 0, \quad \text{and} \quad \Xi \ll 0 \quad \text{if } f < 0.$$

Consequently, in case $\int_0^T V > 0$ we have that, for each $t \in \mathbb{R}$,

$$\psi_{[V,f]}(t) = \frac{\mathrm{e}^{-\int_0^t V}}{\mathrm{e}^{\int_0^T V} - 1} \Xi(t) > 0$$

if $f > 0$, whereas $\psi_{[V,f]}(t) < 0$ if $f < 0$. Similarly, in case $\int_0^T V < 0$, we have that $\psi_{[V,f]} \gg 0$ if $f < 0$, and $\psi_{[V,f]} \ll 0$ if $f > 0$, which concludes the proof of parts (a), (b) and (c).

Finally, suppose $\int_0^T V = 0$. In this case, we already know that (2.5) is necessary for the existence of a solution to (2.4). Suppose (2.5). Then, for each $w_0 \in \mathbb{R}$, we have that (2.6) satisfies

$$w(T) = \mathrm{e}^{-\int_0^T V} \left[w_0 + \int_0^T \mathrm{e}^{\int_0^s V} f(s)\, \mathrm{d}s \right] = w_0 = w(0)$$

and, therefore, it provides us with a solution of (2.4). This concludes the proof. □

As an immediate consequence from Proposition 2.1, in case $\int_0^T V \neq 0$ the linear differential operator (2.3) is a bijection. Clearly, it is continuous. So, it follows from the open mapping theorem that it defines a linear isomorphism between $\mathcal{C}_T^1$ and $\mathcal{C}_T$. Subsequently, we shall denote by J the canonical injection

$$J : \mathcal{C}_T^1 \to \mathcal{C}_T.$$

By Ascoli–Arzela's theorem, J is compact, i.e., it sends bounded sets of $\mathcal{C}_T^1$ into relatively compact subsets of $\mathcal{C}_T$. Therefore, the *resolvent operator*

$$\mathfrak{R}_V := J \left(\frac{\mathrm{d}}{\mathrm{d}t} + V \right)^{-1} : \mathcal{C}_T \to \mathcal{C}_T \tag{2.10}$$

is as well compact. Actually, it is *strongly positive* if $\int_0^T V > 0$, while it is *strongly negative* if $\int_0^T V < 0$, i.e.,

$$\mathfrak{R}_V\big(P \setminus \{0\}\big) \subset \operatorname{Int} P \quad \text{if } \int_0^T V > 0, \tag{2.11}$$

while,

$$\mathfrak{R}_V\big(P \setminus \{0\}\big) \subset -\operatorname{Int} P \quad \text{if } \int_0^T V < 0. \tag{2.12}$$

As a consequence from these positivity properties, one can easily get the main comparison properties associated to Problem (2.4). To state them we need the following elementary concepts.

DEFINITION 2.2. Given $V, f \in \mathcal{C}_T$,

(1) a function $w \in \mathcal{C}_T^1$ is said to be a subsolution (resp. strict subsolution) of (2.4) if $w' + Vw \leqslant f$ (resp. $w' + Vw < f$);

(2) a function $w \in \mathcal{C}_T^1$ is said to be a supersolution (resp. strict supersolution) of (2.4) if $w' + Vw \geqslant f$ (resp. $w' + Vw > f$).

PROPOSITION 2.3. *Suppose* $V, f \in \mathcal{C}_T$, *with* $\int_0^T V \neq 0$. *Then*:

(a) *In case* $\int_0^T V > 0$, *any strict subsolution* w *of* (2.4) *satisfies* $w \ll \psi_{[V,f]}$, *whereas* $w \gg \psi_{[V,f]}$ *for any strict supersolution* w.

(b) *In case* $\int_0^T V < 0$, *any strict subsolution* w *of* (2.4) *satisfies* $w \gg \psi_{[V,f]}$, *whereas* $w \ll \psi_{[V,f]}$ *for any strict supersolution* w.

PROOF. Suppose $\int_0^T V > 0$ and w is a strict subsolution of (2.4). Then, the auxiliary function p defined by

$$p := \left(\frac{\mathrm{d}}{\mathrm{d}t} + V\right)(\psi_{[V,f]} - w)$$

satisfies $p > 0$ and, due to (2.11),

$$\psi_{[V,f]} - w = \mathfrak{R}_V(p) \gg 0.$$

Similarly, when w is a strict supersolution of (2.4),

$$q := \left(\frac{\mathrm{d}}{\mathrm{d}t} + V\right)(w - \psi_{[V,f]}) > 0$$

and (2.11) implies

$$w - \psi_{[V,f]} = \mathfrak{R}_V(q) \gg 0,$$

which concludes the proof of part (a). The proof of part (b) follows the same scheme, though one should use (2.12), instead of (2.11). □

2.2. *The single logistic equation*

The following result characterizes the existence of positive solutions of (2.1).

PROPOSITION 2.4. *Suppose* $\alpha, \beta \in \mathcal{C}_T$ *satisfy* (2.2). *Then,* (2.1) *possesses a positive* T*-periodic solution if, and only if,* $\rho > 0$. *Moreover, it is unique if it exists and if we denote it by* $\theta_{[\rho\alpha,\beta]}$, *then,*

$$\theta_{[\rho\alpha,\beta]} = \frac{1}{\psi_{[\rho\alpha,\beta]}}, \tag{2.13}$$

where $\psi_{[\rho\alpha,\beta]}$ *stands for the unique positive solution of*

$$z' + \rho\alpha z = \beta, \quad z \in \mathcal{C}_T^1. \tag{2.14}$$

PROOF. Note that any positive solution $w \in \mathcal{C}_T^1$ of (2.1) must satisfy $w \gg 0$, since $w' = (\rho\alpha - \beta w)w$. Moreover, the change of variable $w = z^{-1}$ transforms (2.1) into the linear equation (2.14). Thus, the positive T-periodic solutions of (2.1) are in one-to-one correspondence with the positive solutions of problem (2.14).

Suppose $\rho \neq 0$. Then, (2.2) implies $\rho\hat{\alpha} \neq 0$ and, hence, thanks to Proposition 2.1(a), (2.14) possesses a unique solution, $\psi_{[\rho\alpha,\beta]}$. Moreover, thanks to Proposition 2.1(b)–(c), $\psi_{[\rho\alpha,\beta]} \gg 0$ if $\rho > 0$, while $\psi_{[\rho\alpha,\beta]} \ll 0$ if $\rho < 0$.

Finally, note that if $\rho = 0$, then, due to Proposition 2.1(d), (2.14) cannot admit a positive solution, since

$$\int_0^T e^{\rho \int_0^s \alpha} \beta(s)\, ds = \int_0^T \beta(s)\, ds > 0.$$

Combining these features concludes the proof. □

We now analyze some important comparison properties between subsolutions, supersolutions and solutions of (2.1). First, we will introduce some basic concepts.

DEFINITION 2.5. Let $\rho \in \mathbb{R}$ and $\alpha, \beta \in \mathcal{C}_T$. Then,

(1) a function $w \in \mathcal{C}_T^1$ is said to be a subsolution (resp. strict subsolution) of (2.1) if $w' \leqslant \rho\alpha w - \beta w^2$ (resp. $w' < \rho\alpha w - \beta w^2$);

(2) a function $w \in \mathcal{C}_T^1$ is said to be a supersolution (resp. strict supersolution) of (2.1) if $w' \geqslant \rho\alpha w - \beta w^2$ (resp. $w' > \rho\alpha w - \beta w^2$).

PROPOSITION 2.6. *Suppose* $\rho > 0$ *and* $\alpha, \beta \in \mathcal{C}_T$ *satisfy* $\hat{\alpha} > 0$ *and* $\beta > 0$. *Then, any strict subsolution* $\underline{w} \gg 0$ *of* (2.1) *satisfies* $\underline{w} \ll \theta_{[\rho\alpha,\beta]}$, *while any strict supersolution* $\overline{w} \gg 0$ *satisfies* $\overline{w} \gg \theta_{[\rho\alpha,\beta]}$.

PROOF. Suppose $\underline{w} \gg 0$ is a strict subsolution of (2.1). Then, the function $\underline{z} := 1/\underline{w}$ is a strict supersolution of (2.14) and, hence, it follows from Proposition 2.3(a) that $\underline{z} \gg \psi_{[\rho\alpha,\beta]}$. Therefore,

$$\underline{w} \ll \frac{1}{\psi_{[\rho\alpha,\beta]}} = \theta_{[\rho\alpha,\beta]}.$$

Similarly, if $\overline{w} \gg 0$ is a strict supersolution of (2.1), then $\bar{z} := 1/\overline{w}$ is a strict subsolution of (2.14) and, hence, $\bar{z} \ll \psi_{[\rho\alpha,\beta]}$. Consequently, $\overline{w} \gg \theta_{[\rho\alpha,\beta]}$. □

COROLLARY 2.7. *Let, for each* $j \in \{1,2\}$, $\rho_j > 0$ *and* α_j, $\beta_j \in \mathcal{C}_T$ *satisfying* $\alpha_j > 0$ *and* $\beta_j > 0$. *Suppose*

$$\rho_1 \leqslant \rho_2, \quad \alpha_1 \leqslant \alpha_2, \quad \beta_1 \geqslant \beta_2, \quad (\rho_1,\alpha_1,\beta_1) \neq (\rho_2,\alpha_2,\beta_2). \tag{2.15}$$

Then, $\theta_{[\rho_1,\alpha_1,\beta_1]} \ll \theta_{[\rho_2,\alpha_2,\beta_2]}$.

PROOF. Under conditions (2.15), $\theta_{[\rho_1,\alpha_1,\beta_1]} \gg 0$ is a strict subsolution of

$$w' = \rho_2\alpha_2 w - \beta_2 w^2$$

and the conclusion follows from Proposition 2.6. □

2.3. *Point-wise behaviour of the map* $\rho \mapsto \theta_{[\rho\alpha,\beta]}$

In this section we regard to the unique positive solution of (2.1), $\theta_{[\rho\alpha,\beta]}$, as a map depending on the parameter $\rho > 0$ in order to analyze some sharp properties of the global bifurcation diagram of non-negative solutions of (2.1). Our main result reads as follows.

THEOREM 2.8. *Suppose* $\hat{\alpha} > 0$ *and* $\beta > 0$, *and set*

$$\Theta(\rho) := \theta_{[\rho\alpha,\beta]} \in \mathcal{C}^1_T, \quad \rho > 0. \tag{2.16}$$

Then, the map $(0,\infty) \to \mathcal{C}^1_T$, $\rho \mapsto \Theta(\rho)$, *is real analytic and it possesses the following asymptotic expansion at* $\rho = 0$

$$\Theta(\rho) = \frac{\hat{\alpha}}{\hat{\beta}}\left[\rho + \rho^2 I_2 + \mathrm{O}\left(\rho^3\right)\right] \quad \text{as } \rho \downarrow 0, \tag{2.17}$$

where I_2 *stands for the function defined by*

$$I_2(t) := \int_0^t \alpha - \frac{\hat{\alpha}}{\hat{\beta}} \int_0^t \beta - \frac{1}{T}\left(\int_0^T\int_0^t \alpha - \frac{\hat{\alpha}}{\hat{\beta}}\int_0^T\int_0^t \beta\right), \quad t \in \mathbb{R}.$$

In particular,

$$\lim_{\rho\downarrow 0} \left\|\Theta(\rho)\right\|_{\mathcal{C}_T} = 0. \tag{2.18}$$

If, in addition, $\alpha > 0$, *then the map* $(0,\infty) \to \mathcal{C}_T$, $\rho \mapsto \Theta(\rho)$, *is strongly increasing in the sense that* $\Theta(\rho) \gg \Theta(\tilde{\rho})$ *if* $\rho > \tilde{\rho}$. *Further, if* $\alpha \gg 0$ *and* $\beta \gg 0$, *then, for each* $\rho > 0$,

$$\frac{\alpha_L}{\beta_M}\,\rho \leqslant \Theta(\rho) \leqslant \frac{\alpha_M}{\beta_L}\,\rho \tag{2.19}$$

and

$$\lim_{\rho\uparrow\infty} \frac{\Theta(\rho)}{\rho} = \frac{\alpha}{\beta} \quad \text{in } \mathcal{C}_T. \tag{2.20}$$

PROOF. Note that the solutions of (2.1) are the zeroes of the non-linear operator $\mathfrak{F} : \mathbb{R} \times \mathcal{C}_T^1 \to \mathcal{C}_T$ defined by

$$\mathfrak{F}(\rho, w) := w' - \rho\alpha w + \beta w^2, \tag{2.21}$$

which is real analytic. Fix $\rho_0 > 0$. Then,

$$\mathfrak{F}\bigl(\rho_0, \Theta(\rho_0)\bigr) = 0$$

and $D_u\mathfrak{F}(\rho_0, \Theta(\rho_0)) \in \mathcal{L}(\mathcal{C}_T^1; \mathcal{C}_T)$ is given through

$$D_u\mathfrak{F}\bigl(\rho_0, \Theta(\rho_0)\bigr) := \frac{\mathrm{d}}{\mathrm{d}t} + 2\beta\Theta(\rho_0) - \rho_0\alpha. \tag{2.22}$$

Since $\Theta(\rho_0) \gg 0$ satisfies

$$\frac{\mathrm{d}\Theta(\rho_0)}{\mathrm{d}t} = \rho_0\alpha\Theta(\rho_0) - \beta\bigl[\Theta(\rho_0)\bigr]^2,$$

division by $\Theta(\rho_0)$ and integration in $[0,T]$ gives

$$0 = \operatorname{Log}\frac{\Theta(\rho_0)(T)}{\Theta(\rho_0)(0)} = \int_0^T \bigl[\rho_0\alpha - \beta\Theta(\rho_0)\bigr] = 0$$

and, hence,

$$\int_0^T \bigl[2\beta\Theta(\rho_0) - \rho_0\alpha\bigr] = \int_0^T \beta(t)\Theta(\rho_0)(t)\,\mathrm{d}t > 0,$$

since $\beta > 0$. Thus, thanks to Proposition 2.1, $D_u\mathfrak{F}(\rho_0, \Theta(\rho_0))$ is a linear isomorphism between $\mathcal{C}_T^1$ and $\mathcal{C}_T$. Therefore, thanks to the implicit function theorem, there exist $\varepsilon \in (0,\rho_0)$, $\delta > 0$, and a unique real analytic map

$$W : (\rho_0 - \varepsilon, \rho_0 + \varepsilon) \to \bigl\{w \in \mathcal{C}_T^1\colon\ \|w - \Theta(\rho_0)\|_{\mathcal{C}_T^1} < \delta\bigr\}$$

such that $W(\rho_0) = \Theta(\rho_0)$, $\mathfrak{F}(\rho, W(\rho)) = 0$ if $|\rho - \rho_0| < \varepsilon$, and $w = W(\rho)$ if $\mathfrak{F}(\rho, w) = 0$ with $|\rho - \rho_0| < \varepsilon$ and $\|w - \Theta(\rho_0)\|_{\mathcal{C}^1_T} < \delta$. As $W(\rho_0) = \Theta(\rho_0) \gg 0$, necessarily $W(\rho) \gg 0$ for $\rho \sim \rho_0$, and, therefore, $W(\rho) = \Theta(\rho)$, by the uniqueness of the positive solution of (2.1). This shows that $\rho \mapsto \Theta(\rho)$ is real analytic.

Although the fact that the map $(0, \infty) \to \mathcal{C}_T$, $\rho \mapsto \Theta(\rho)$, is strictly increasing if $\alpha > 0$ is a consequence from Corollary 2.7, it should be noted that implicit differentiation in

$$\mathfrak{F}\big(\rho, \Theta(\rho)\big) = 0$$

gives rise to

$$\left(\frac{\mathrm{d}}{\mathrm{d}t} + 2\beta\Theta(\rho) - \rho\alpha\right)\frac{\mathrm{d}\Theta}{\mathrm{d}\rho}(\rho) = \alpha\Theta(\rho) > 0$$

and, hence,

$$\frac{\mathrm{d}\Theta}{\mathrm{d}\rho}(\rho) = \left(\frac{\mathrm{d}}{\mathrm{d}t} + 2\beta\Theta(\rho) - \rho\alpha\right)^{-1}\big(\alpha\Theta(\rho)\big) \gg 0,$$

because of (2.11).

To prove (2.17) we will use a celebrated device introduced by M.G. Crandall and P.H. Rabinowitz [6]. Note that

$$D_u\mathfrak{F}(0, 0) = \frac{\mathrm{d}}{\mathrm{d}t} : \mathcal{C}^1_T \to \mathcal{C}_T$$

and, hence,

$$N\big[D_u\mathfrak{F}(0, 0)\big] = \operatorname{span}[1].$$

Moreover,

$$\mathcal{C}^1_T = N\big[D_u\mathfrak{F}(0, 0)\big] \oplus Y, \quad Y := \left\{y \in \mathcal{C}^1_T \colon \int_0^T y = 0\right\}.$$

Indeed, any $w \in \mathcal{C}^1_T$ admits a unique decomposition as

$$w = x + y, \quad x \in \mathbb{R},\ y \in Y.$$

Actually,

$$x = \hat{w}, \quad y = w - \hat{w}.$$

Now, consider the auxiliary operator $\mathfrak{G} : \mathbb{R}^2 \times Y \to \mathcal{C}_T$ defined by

$$\mathfrak{G}(s, \rho, y) := y' - \rho\alpha(1 + y) + \beta s(1 + y)^2, \quad (s, \rho, y) \in \mathbb{R}^2 \times Y. \tag{2.23}$$

It should be noted that $\mathfrak{G}(s,\rho,y)=0$ implies $\mathfrak{F}(\rho,s(1+y))=0$. It is rather clear that $\mathfrak{G}$ is a real analytic operator such that $\mathfrak{G}(0,0,0)=0$. Moreover, the operator $D_{(\rho,y)}\mathfrak{G}(0,0,0):\mathbb{R}\times Y\to\mathcal{C}_T$ is given by

$$D_{(\rho,y)}\mathfrak{G}(0,0,0)(\rho,y)=y'-\rho\alpha,\quad (\rho,y)\in\mathbb{R}\times Y,$$

and, so, it is a linear isomorphism. Indeed, if for some $(\rho,y)\in\mathbb{R}\times Y$ one has that $y'=\rho\alpha$, then integrating in $[0,T]$ gives $\rho\hat{\alpha}=0$ and, hence, $\rho=0$, since $\hat{\alpha}>0$. Thus, $y'=0$ and, therefore, y is constant. Consequently, as it has zero average, we obtain that $y=0$, which concludes the proof of the injectivity. Now, fix $f\in\mathcal{C}_T$. Then, it is straightforward to check that

$$y(t):=-\frac{\hat{f}}{\hat{\alpha}}\int_0^t\alpha+\int_0^t f-\frac{1}{T}\left(-\frac{\hat{f}}{\hat{\alpha}}\int_0^T\int_0^t\alpha+\int_0^T\int_0^t f\right),\quad t\in\mathbb{R},$$

provides us with the unique element of Y solving

$$D_{(\rho,y)}\mathfrak{G}(0,0,0)(\rho,y)=f,\quad \rho:=-\frac{\hat{f}}{\hat{\alpha}}.$$

Therefore, thanks to the implicit function theorem, there exist $s_0>0$, $\delta>0$, and a unique real analytic map

$$(\rho,y):(-s_0,s_0)\to(-\delta,\delta)\times\left\{y\in Y:\ \|y\|_{\mathcal{C}_T^1}<\delta\right\}$$

such that $(\rho(0),y(0))=(0,0)$, $\mathfrak{G}(s,\rho(s),y(s))=0$ for each $s\in(-s_0,s_0)$, and $(\rho,y)=(\rho(s),y(s))$ if $\mathfrak{G}(s,\rho,y)=0$ with $|s|<s_0$, $|\rho|<\delta$, and $\|y\|_{\mathcal{C}_T^1}<\delta$. In particular,

$$\mathfrak{F}\big(\rho(s),s\big(1+y(s)\big)\big)=0,\quad |s|<s_0,$$

and, so, for sufficiently small $s>0$,

$$(\rho,w):=\big(\rho(s),s\big(1+y(s)\big)\big)$$

provides us with a positive T-periodic solution of (2.1). Necessarily, for sufficiently small $s>0$, we have that

$$s\big(1+y(s)\big)=\Theta\big(\rho(s)\big)\tag{2.24}$$

because of the uniqueness of the positive solution of (2.1). Now, in order to find the lowest order terms of the local developments

$$\rho(s)=\sum_{n=1}^{\infty}\rho_n s^n,\quad y(s)=\sum_{n=1}^{\infty}s^n y_n,\quad y_n\in Y,\ n\geqslant 1,\tag{2.25}$$

we substitute (2.25) into the equation of the zeroes of $\mathfrak{G}$. Then, we get

$$\sum_{n=1}^{\infty} s^n y_n' = \left[\alpha \sum_{n=1}^{\infty} \rho_n s^n - s\beta\left(1 + \sum_{n=1}^{\infty} s^n y_n\right)\right]\left(1 + \sum_{n=1}^{\infty} s^n y_n\right)$$

and identifying terms of order one in both members gives

$$y_1' = \rho_1 \alpha - \beta.$$

Thus,

$$\rho_1 = \frac{\hat{\beta}}{\hat{\alpha}}, \quad y_1(t) = \rho_1 \int_0^t \alpha - \int_0^t \beta - \frac{1}{T}\left(\rho_1 \int_0^T \int_0^t \alpha - \int_0^T \int_0^t \beta\right)$$

and, therefore, (2.24) shows that

$$\rho(s) = \rho_1 s + \mathrm{O}(s^2) \quad \text{and} \quad \Theta(\rho(s)) = s\left(1 + s\, y_1(t) + \mathrm{O}(s^2)\right) \tag{2.26}$$

as $s \downarrow 0$. Thanks again to the implicit function theorem, one can eliminate s as a function of ρ at $\rho = 0$ from the identity

$$\rho_1 s + \mathrm{O}(s^2) = \rho.$$

Actually,

$$s = \frac{1}{\rho_1}\rho + \mathrm{O}(\rho^2) = \frac{\hat{\alpha}}{\hat{\beta}}\rho + \mathrm{O}(\rho^2),$$

and, so, substituting this expansion into the second identity of (2.26) shows that

$$\Theta(\rho) = \frac{\hat{\alpha}}{\hat{\beta}}\left[\rho + \frac{\hat{\alpha}}{\hat{\beta}} y_1 \rho^2 + \mathrm{O}(\rho^3)\right]$$

as $\rho \downarrow 0$, which provides us with the asymptotic expansion (2.17).

Subsequently, we suppose that $\alpha \gg 0$ and $\beta \gg 0$. The global estimates (2.19) and (2.20) are consequences from Proposition 2.6. Indeed, setting $\Theta := \Theta(\rho)$, we have that

$$\rho\alpha_L \Theta - \beta_M \Theta^2 \leqslant \Theta' = \rho\alpha\Theta - \beta\Theta^2 \leqslant \rho\alpha_M \Theta - \beta_L \Theta^2,$$

and, hence, for each $\rho > 0$, $\Theta(\rho)$ is a positive subsolution of $w' = \rho\alpha_M w - \beta_L w^2$ and a positive supersolution of $w' = \rho\alpha_L w - \beta_M w^2$. Therefore, (2.19) follows from Proposition 2.6 by taking into account that $\frac{\alpha_M}{\beta_L}\rho$ and $\frac{\alpha_L}{\beta_M}\rho$ provide us with the unique T-periodic positive solutions of each of these autonomous equations.

Now, fix $\delta > 0$ sufficiently small so that $\frac{\alpha}{\beta} \gg \delta$, consider two functions $\underline{\theta}$, $\bar{\theta} \in \mathcal{C}^1_T$ such that

$$\frac{\alpha}{\beta} - \delta < \underline{\theta} < \frac{\alpha}{\beta} - \frac{\delta}{2}, \qquad \frac{\alpha}{\beta} + \frac{\delta}{2} < \bar{\theta} < \frac{\alpha}{\beta} + \delta, \tag{2.27}$$

and set

$$\underline{w} := \rho\,\underline{\theta}, \qquad \overline{w} := \rho\,\bar{\theta}.$$

Then, for each sufficiently large $\rho > 0$, say $\rho \geqslant \rho_0$, we have that

$$\rho\alpha\overline{w} - \beta\overline{w}^2 = \rho^2\beta\bar{\theta}\left(\frac{\alpha}{\beta} - \bar{\theta}\right) < -\frac{\delta}{2}\rho^2\beta\bar{\theta} \leqslant \rho\bar{\theta}' = \overline{w}',$$

and

$$\rho\alpha\underline{w} - \beta\underline{w}^2 = \rho^2\beta\underline{\theta}\left(\frac{\alpha}{\beta} - \underline{\theta}\right) > \frac{\delta}{2}\rho^2\beta\underline{\theta} \geqslant \rho\underline{\theta}' = \underline{w}'.$$

Consequently, for each $\rho \geqslant \rho_0$, $\underline{w}$ and $\overline{w}$ provide with a strict subsolution and a strict supersolution of (2.1), respectively, and, hence, thanks to Proposition 2.6,

$$\underline{w} = \rho\,\underline{\theta} \ll \Theta(\rho) \ll \overline{w} = \rho\,\bar{\theta}.$$

Thus, it follows from (2.27) that, for each $\rho \geqslant \rho_0$,

$$\frac{\alpha}{\beta} - \delta \ll \frac{\Theta(\rho)}{\rho} \ll \frac{\alpha}{\beta} + \delta.$$

Therefore, passing to the limit as $\rho \uparrow \infty$, shows that

$$\frac{\alpha}{\beta} - \delta \leqslant \liminf_{\rho\uparrow\infty} \frac{\Theta(\rho)}{\rho} \leqslant \limsup_{\rho\uparrow\infty} \frac{\Theta(\rho)}{\rho} \leqslant \frac{\alpha}{\beta} + \delta.$$

As these inequalities are valid for any $\delta > 0$, the proof of (2.20) is concluded, as well as the proof of the theorem. □

It should be noted that the strong monotonicity of $\Theta(\rho)$ is lost when α changes of sign. Indeed, suppose that, for some sufficiently small $\delta > 0$, $\beta(t) = 0$ and $\alpha(t) < 0$ for each $t \in [0, \delta]$. Then, for each $t \in [0, \delta]$ we have that

$$\theta_{[\rho\alpha,\beta]}(t) = \mathrm{e}^{\rho\int_0^t \alpha}\theta_{[\rho\alpha,\beta]}(0).$$

Since $\int_0^t \alpha < 0$, the map $\rho \mapsto \theta_{[\rho\alpha,\beta]}(t)$ is decreasing for each $t \in (0, \delta]$.

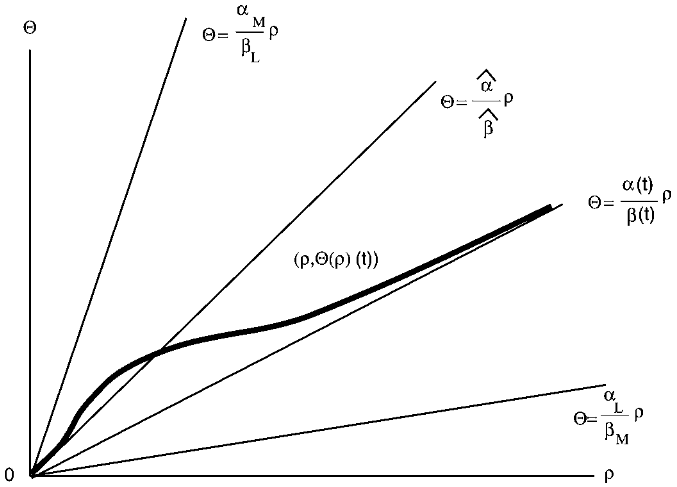

Fig. 1. Graph of $\rho \mapsto \Theta(\rho)(t)$ in case $\alpha \gg 0$ and $\beta \gg 0$.

In Fig. 1 we have represented the bifurcation diagram $(\rho, \Theta(\rho)(t))$ for some $t \in \mathbb{R}$ in the (ρ, Θ)-plane in the special, though important, case when $\alpha \gg 0$ and $\beta \gg 0$. Thanks to (2.19) the curve $\rho \mapsto \Theta(\rho)(t)$ must be confined in between the straight lines $\Theta = \frac{\alpha_L}{\beta_M}\rho$ and $\Theta = \frac{\alpha_M}{\beta_L}\rho$, and, due to (2.17) and (2.20), its tangents at $\rho = 0$ and $\rho = \infty$ are

$$\Theta = \frac{\hat{\alpha}}{\hat{\beta}}\rho \quad \text{and} \quad \Theta = \frac{\alpha(t)}{\beta(t)}\rho,$$

respectively.

2.4. *Attractiveness of* $\theta_{[\rho\alpha,\beta]}$

Note that the linearized equations of (2.1) at $w = 0$ and $w = \Theta(\rho)$ are given by

$$w' = \rho\alpha w \quad \text{and} \quad w' = \big[\rho\alpha - 2\beta\Theta(\rho)\big]w,$$

respectively, whose Floquet multipliers are

$$\mathrm{e}^{\rho\int_0^T \alpha} \quad \text{and} \quad \mathrm{e}^{\int_0^T [\rho\alpha - 2\beta\Theta(\rho)]}.$$

As a result, $w = 0$ is linearly stable if $\rho < 0$, linearly neutrally stable if $\rho = 0$ and linearly unstable if $\rho > 0$. Moreover, in the proof of Theorem 2.8 we have seen that, for each $\rho > 0$,

$$\int_0^T \big[\rho\alpha - \beta\Theta(\rho)\big] = 0, \tag{2.28}$$

and, hence,

$$\mathrm{e}^{\int_0^T [\rho\alpha - 2\beta\Theta(\rho)]} = \mathrm{e}^{-\int_0^T [\beta\Theta(\rho)]} < 1.$$

Therefore, $\Theta(\rho)$ is linearly stable. Actually, it is easy to see that 0 is a global attractor of (2.1) if $\rho \leqslant 0$, whereas $\Theta(\rho)$ attracts to all positive solutions of (2.1) if $\rho > 0$.

3. Linearized stability of the semi-trivial solutions

Thanks to Proposition 2.4, (1.2) possesses a semi-trivial state—throughout the remaining of the chapter, positive—of the form $(u, 0)$ if and only if $\lambda > 0$. Moreover, in such case, $(\theta_{[\lambda\ell,a]}, 0)$ is the unique semi-trivial state of this form. Similarly, $(0, \theta_{[\mu m,d]})$ provides us with the unique semi-trivial state of (2.1) of the form $(0, v)$, and it exists if and only if $\mu > 0$. The following result characterizes the stability of these states and the stability of the trivial state $(0, 0)$.

PROPOSITION 3.1. *The following assertions are true*:

(a) $(0, 0)$ *is linearly stable if* $\lambda < 0$ *and* $\mu < 0$, *and it is linearly unstable if either* $\lambda > 0$ *or* $\mu > 0$.

(b) *Suppose* $\lambda > 0$. *Then,* $(\theta_{[\lambda\ell,a]}, 0)$ *is linearly unstable if and only if*

$$\mu > \frac{1}{T}\int_0^T c(t)\theta_{[\lambda\ell,a]}(t)\,\mathrm{d}t, \tag{3.1}$$

and linearly stable if and only if

$$\mu < \frac{1}{T}\int_0^T c(t)\theta_{[\lambda\ell,a]}(t)\,\mathrm{d}t. \tag{3.2}$$

Consequently, the **curve of change of stability** *of* $(\theta_{[\lambda\ell,a]}, 0)$ *in the* (λ, μ)*-plane is given through its curve of neutral stability*

$$\mu = f(\lambda) := \frac{1}{T}\int_0^T c(t)\theta_{[\lambda\ell,a]}(t)\,\mathrm{d}t. \tag{3.3}$$

(c) *Suppose* $\mu > 0$. *Then,* $(0, \theta_{[\mu m,d]})$ *is linearly unstable if and only if*

$$\lambda > \frac{1}{T}\int_0^T b(t)\theta_{[\mu m,d]}(t)\,\mathrm{d}t, \tag{3.4}$$

and linearly stable if and only if

$$\lambda < \frac{1}{T}\int_0^T b(t)\theta_{[\mu m,d]}(t)\,\mathrm{d}t. \tag{3.5}$$

Consequently, the **curve of change of stability** *of* $(0, \theta_{[\mu m,d]})$ *in the* (λ, μ)*-plane is given through its curve of neutral stability*

$$\lambda = g(\mu) := \frac{1}{T}\int_0^T b(t)\theta_{[\mu m,d]}(t)\,\mathrm{d}t. \tag{3.6}$$

PROOF. The linearization of (1.2) at any solution $(u_0, v_0) \in \mathcal{C}^1_T \times \mathcal{C}^1_T$ is given by

$$\begin{cases} u' = (\lambda\,\ell - 2au_0 - bv_0)u - bu_0v, \\ v' = -cv_0u + (\mu\,m - 2dv_0 - cu_0)v. \end{cases} \tag{3.7}$$

When $(u_0, v_0) = (0, 0)$, (3.7) becomes into

$$\begin{cases} u' = \lambda\ell u, \\ v' = \mu m v, \end{cases}$$

whose Poincaré map is given by

$$\mathfrak{P}(x, y) = \begin{pmatrix} \mathrm{e}^{\lambda T} & 0 \\ 0 & \mathrm{e}^{\mu T} \end{pmatrix}\begin{pmatrix} x \\ y \end{pmatrix}, \quad (x, y) \in \mathbb{R}^2,$$

since $\hat{\ell} = \hat{m} = 1$. Thus, its Floquet multipliers, $\mathrm{e}^{\lambda T}$ and $\mathrm{e}^{\mu T}$, are less than one if $\lambda < 0$ and $\mu < 0$, while some of them is greater than one if either $\lambda > 0$ or $\mu > 0$, which concludes the proof of part (a).

When $(u_0, v_0) = (\theta_{[\lambda\ell,a]}, 0)$, (3.7) becomes into

$$\begin{cases} u' = (\lambda\,\ell - 2a\theta_{[\lambda\ell,a]})u - b\theta_{[\lambda\ell,a]}v, \\ v' = (\mu\,m - c\theta_{[\lambda\ell,a]})v, \end{cases} \tag{3.8}$$

and its associated Poincaré map is given by

$$\mathfrak{P}(x, y) = \begin{pmatrix} \mathrm{e}^{\int_0^T (\lambda\ell - 2a\theta_{[\lambda\ell,a]})} & E \\ 0 & \mathrm{e}^{\int_0^T (\mu m - c\theta_{[\lambda\ell,a]})} \end{pmatrix}\begin{pmatrix} x \\ y \end{pmatrix}, \quad (x, y) \in \mathbb{R}^2,$$

for some constant $E \in \mathbb{R}$ whose explicit knowledge is not important here. Thanks to (2.28),

$$\int_0^T (\lambda\ell - a\theta_{[\lambda\ell,a]}) = 0$$

and, hence,

$$0 < \mathrm{e}^{\int_0^T (\lambda\ell - 2a\theta_{[\lambda\ell,a]})} = \mathrm{e}^{-\int_0^T a(t)\theta_{[\lambda\ell,a]}(t)\,\mathrm{d}t} < 1.$$

Consequently, the attractive character of $(\theta_{[\lambda\ell,a]},0)$ is given by the remaining Floquet multiplier

$$\nu := \mathrm{e}^{\int_0^T(\mu m - c\theta_{[\lambda\ell,a]})} = \mathrm{e}^{\mu T - \int_0^T c(t)\theta_{[\lambda\ell,a]}(t)\,\mathrm{d}t}.$$

As $\nu > 1$ when (3.1) is satisfied, $\nu = 1$ if (3.3) is satisfied, and $0 < \nu < 1$ under condition (3.2), the proof of part (b) is concluded. Part (c) follows by symmetry. This ends the proof. □

4. The curves of change of stability of the semi-trivial positive solutions

In this section we shall study some global properties of the curves of neutral stability (3.3) and (3.6) of the semi-trivial solutions of (1.2). Such analysis is imperative in order to ascertain the shape of each of the following regions within the parameter space (λ,μ):

$$\begin{aligned} \mathrm{R}_{\mathrm{uu}} &:= \bigl\{(\lambda,\mu)\in(0,\infty)^2\colon\ (\theta_{[\lambda\ell,a]},0) \text{ and } (0,\theta_{[\mu m,d]}) \text{ are l.u.}\bigr\},\\ \mathrm{R}_{\mathrm{ss}} &:= \bigl\{(\lambda,\mu)\in(0,\infty)^2\colon\ (\theta_{[\lambda\ell,a]},0) \text{ and } (0,\theta_{[\mu m,d]}) \text{ are l.s.}\bigr\}, \end{aligned} \tag{4.1}$$

$$\begin{aligned} \mathrm{R}_{\mathrm{su}} &:= \bigl\{(\lambda,\mu)\in(0,\infty)^2\colon\ (\theta_{[\lambda\ell,a]},0) \text{ is l.s., } (0,\theta_{[\mu m,d]}) \text{ is l.u.}\bigr\},\\ \mathrm{R}_{\mathrm{us}} &:= \bigl\{(\lambda,\mu)\in(0,\infty)^2\colon\ (\theta_{[\lambda\ell,a]},0) \text{ is l.u., } (0,\theta_{[\mu m,d]}) \text{ is l.s.}\bigr\}, \end{aligned} \tag{4.2}$$

$$\begin{aligned} \mathrm{R}_{\mathrm{u}\star} &:= \bigl\{(\lambda,\mu)\in(0,\infty)\times(-\infty,0]\colon\ (\theta_{[\lambda\ell,a]},0) \text{ is l.u.}\bigr\},\\ \mathrm{R}_{\mathrm{s}\star} &:= \bigl\{(\lambda,\mu)\in(0,\infty)\times(-\infty,0]\colon\ (\theta_{[\lambda\ell,a]},0) \text{ is l.s.}\bigr\}, \end{aligned} \tag{4.3}$$

$$\begin{aligned} \mathrm{R}_{\star\mathrm{u}} &:= \bigl\{(\lambda,\mu)\in(-\infty,0]\times(0,\infty)\colon\ (0,\theta_{[\mu m,d]}) \text{ is l.u.}\bigr\},\\ \mathrm{R}_{\star\mathrm{s}} &:= \bigl\{(\lambda,\mu)\in(-\infty,0]\times(0,\infty)\colon\ (0,\theta_{[\mu m,d]}) \text{ is l.s.}\bigr\}, \end{aligned} \tag{4.4}$$

where *l.u.* stands for *linearly unstable* and *l.s.* for *linearly stable*. As the global behaviour of the curves of neutral stability of the semi-trivial states is strongly based upon the nature of the model under study, i.e., under the sign properties of the interaction coefficient functions $b(t)$ and $c(t)$, in the subsequent discussion we will have to distinguish several different cases. We begin the section by giving a general result which is a straightforward consequence from Theorem 2.8.

THEOREM 4.1. *Suppose $\alpha,\beta,\gamma\in\mathcal{C}_T$ satisfy*

$$\alpha \gg 0,\quad \beta\gg 0,\quad \hat\alpha = \hat\beta = 1, \tag{4.5}$$

and consider the function

$$N(\rho) := \frac{1}{T}\int_0^T \gamma(t)\theta_{[\rho\alpha,\beta]}(t)\,\mathrm{d}t,\quad \rho>0. \tag{4.6}$$

Then,

$$N(\rho) = \hat{\gamma}\,\rho + \frac{1}{T}\int_0^T \gamma(t) I_2(t)\,\mathrm{d}t\,\rho^2 + \mathrm{O}\big(\rho^3\big) \quad \text{as } \rho \downarrow 0, \tag{4.7}$$

where

$$I_2(t) := \int_0^t (\alpha - \beta) - \frac{1}{T}\int_0^T\int_0^t (\alpha - \beta), \quad t \in \mathbb{R}, \tag{4.8}$$

and

$$\lim_{\rho\uparrow\infty} \frac{N(\rho)}{\rho} = \frac{1}{T}\int_0^T \gamma(t)\frac{\alpha(t)}{\beta(t)}\,\mathrm{d}t. \tag{4.9}$$

Moreover, $\rho \mapsto N(\rho)$ *is increasing if* $\gamma > 0$*, decreasing if* $\gamma < 0$*, and, in general, is far from monotone if* γ *changes of sign. In such case,* (4.9) *can be either negative, or positive, or zero, according to the value of the average on its right-hand side.*

PROOF. By (4.5), it follows from Theorem 2.8 that

$$\theta_{[\rho\alpha,\beta]} = \rho + I_2\,\rho^2 + \mathrm{O}\big(\rho^3\big) \quad \text{as } \rho \downarrow 0.$$

Thus,

$$N(\rho) := \frac{1}{T}\int_0^T \gamma(t)\theta_{[\rho\alpha,\beta]}(t)\,\mathrm{d}t = \hat{\gamma}\,\rho + \frac{1}{T}\int_0^T \gamma(t) I_2(t)\,\mathrm{d}t\rho^2 + \mathrm{O}\big(\rho^3\big),$$

which is (4.7). The validity of (4.9) is an immediate consequence from (2.20). The remaining assertions of the theorem are obvious, since $\theta_{[\rho\alpha,\beta]} \gg 0$. □

It should be noted that, in general, nothing can be said about the concavity of $N(\rho)$ at $\rho = 0$. Indeed, since I_2 changes of sign if $I_2 \neq 0$, because $\hat{I}_2 = 0$, the average of the function γI_2 can have any sign we wish by choosing and adequate γ that may be taken either positive, or negative, or changing of sign, in strong contrast with the autonomous case, where $N(\rho) = \gamma\rho$ for every $\rho > 0$.

4.1. *The species u and v compete* ($b > 0$ *and* $c > 0$)

Besides (1.7), throughout this section we assume that

$$\ell \gg 0, \quad m \gg 0, \quad a \gg 0, \quad d \gg 0, \quad b > 0, \quad c > 0, \tag{4.10}$$

though most of our discussion can be easily adapted to cover much weaker requirements. Under assumptions (4.10), the curves of neutral stability of the semi-trivial states

$(\theta_{[\lambda\ell,a]},0)$ and $(0,\theta_{[\mu m,d]})$, (3.3) and (3.6), are increasing in λ and μ, respectively, and satisfy

$$f(\lambda)>0,\quad g(\mu)>0,\quad (\lambda,\mu)\in(0,\infty)^2. \tag{4.11}$$

It should be noted that these are the curves delimiting the regions defined by (4.1) and (4.2). Thanks to Theorem 4.1, the tangents of these curves at $(\lambda,\mu)=(0,0)$ are given by

$$\mu=\hat{c}\lambda \quad\text{and}\quad \lambda=\hat{b}\mu, \tag{4.12}$$

respectively, as for the autonomous counterpart of (1.2)—where these are the curves of neutral stability of $(\lambda,0)$ and $(0,\mu)$—and their tangents at infinity are given by

$$\begin{aligned} \mu&=\alpha\lambda, \qquad \alpha:=\frac{1}{T}\int_0^T c(t)\frac{\ell(t)}{a(t)}\,\mathrm{d}t,\\ \lambda&=\beta\mu, \qquad \beta:=\frac{1}{T}\int_0^T b(t)\frac{m(t)}{d(t)}\,\mathrm{d}t, \end{aligned} \tag{4.13}$$

respectively. In strong contrast with the autonomous case—where (4.12) and (4.13) are the same straight lines—as a consequence from the non-autonomous character of (1.2), the *relative positions* of the straight lines (4.12) and (4.13) can be inter-exchanged at $(\lambda,\mu)=(0,0)$ and at infinity, so entailing the existence of a crossing point between the curves of change of stability of the semi-trivial states; a feature of great significance from the point of view of the applications, as it might allow us designing environments where none of the competitors is driven to extinction by the other. Most precisely, there are admissible choices of the function coefficients a, b, c, d, ℓ and m, for which either

$$\hat{b}\hat{c}<1 \quad\text{and}\quad \alpha\beta=\frac{1}{T}\int_0^T c(t)\frac{\ell(t)}{a(t)}\,\mathrm{d}t\cdot\frac{1}{T}\int_0^T b(t)\frac{m(t)}{d(t)}\,\mathrm{d}t>1, \tag{4.14}$$

or else

$$\hat{b}\hat{c}>1 \quad\text{and}\quad \alpha\beta=\frac{1}{T}\int_0^T c(t)\frac{\ell(t)}{a(t)}\,\mathrm{d}t\cdot\frac{1}{T}\int_0^T b(t)\frac{m(t)}{d(t)}\,\mathrm{d}t<1. \tag{4.15}$$

In such circumstances, as the curves $\mu=f(\lambda)$, $\lambda>0$, and $\lambda=g(\mu)$, $\mu>0$, are real analytic, they must cross at most at a finite number of points—at least one—whose total sum of contact orders must be an odd integer number. To construct examples satisfying any of these requirements one can make the following choices:

$$a=d=1,\quad \ell:=1+\ell_1\sin\left(\frac{2\pi}{T}\,\cdot\right),\quad m:=1+m_1\sin\left(\frac{2\pi}{T}\,\cdot\right), \tag{4.16}$$

for some constants $\ell_1, m_1\in(-1,1)$, and

$$b:=b_0+b_1\sin\left(\frac{2\pi}{T}\,\cdot\right),\quad c:=c_0+c_1\sin\left(\frac{2\pi}{T}\,\cdot\right), \tag{4.17}$$

for some constants

$$b_0 > 0, \quad c_0 > 0, \quad b_1 \in (-b_0, b_0), \quad c_1 \in (-c_0, c_0).$$

For these choices, we have that

$$\hat{b} = b_0, \quad \hat{c} = c_0,$$

and

$$\alpha = \frac{1}{T}\int_0^T c(t)\frac{\ell(t)}{a(t)}\,\mathrm{d}t = c_0 + \frac{1}{2}c_1\ell_1, \quad \beta = \frac{1}{T}\int_0^T b(t)\frac{m(t)}{d(t)}\,\mathrm{d}t = b_0 + \frac{1}{2}b_1 m_1.$$

Thus, (4.14) and (4.15) are equivalent to

$$b_0c_0 < 1 \quad \text{and} \quad \left(c_0 + \frac{1}{2}c_1\ell_1\right)\left(b_0 + \frac{1}{2}b_1m_1\right) > 1, \tag{4.18}$$

and

$$b_0c_0 > 1 \quad \text{and} \quad \left(c_0 + \frac{1}{2}c_1\ell_1\right)\left(b_0 + \frac{1}{2}b_1m_1\right) < 1, \tag{4.19}$$

respectively. We now show that any of these conditions can be reached by an adequate choice of the several constants involved in their settings. Take, for sufficiently small $\varepsilon > 0$,

$$b_0 = c_0 = 1 - \varepsilon, \quad b_1 = c_1 = 1 - 2\varepsilon.$$

Then, the function $p(\varepsilon)$ defined by

$$p(\varepsilon) := \left[1 - \varepsilon + \frac{1}{2}(1 - 2\varepsilon)\ell_1\right]\left[1 - \varepsilon + \frac{1}{2}(1 - 2\varepsilon)m_1\right], \quad \varepsilon > 0,$$

satisfies

$$p(0) = 1 + \frac{1}{2}(\ell_1 + m_1) + \frac{1}{4}\ell_1 m_1$$

and, hence, $p(0) > 1$ if $\ell_1 > 0$ and $m_1 > 0$. Thus, if we choose ℓ_1, $m_1 \in (0, 1)$, then, for sufficiently small $\varepsilon > 0$, we have that $p(\varepsilon) > 1$, by continuity, and, consequently, (4.18) is satisfied. On the contrary, choosing

$$b_0 = c_0 = 1 + \varepsilon, \quad b_1 = c_1 = 1,$$

the auxiliary function $n(\varepsilon)$ defined by

$$n(\varepsilon) := \left[1 + \varepsilon + \frac{1}{2}\ell_1\right]\left[1 + \varepsilon + \frac{1}{2}m_1\right], \quad \varepsilon > 0,$$

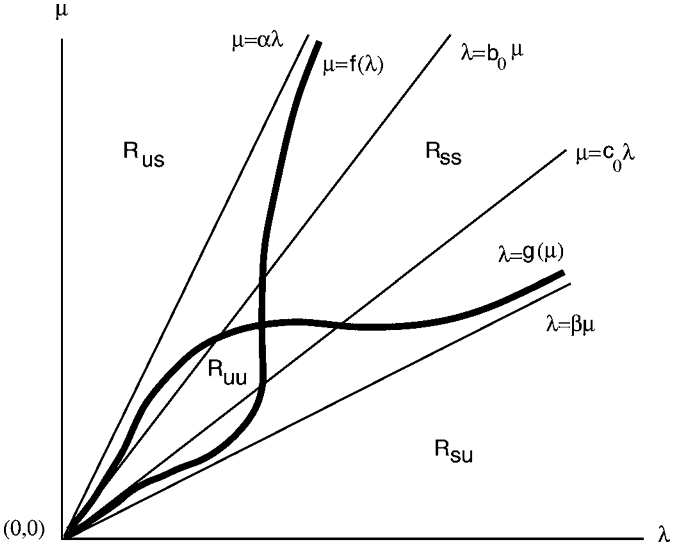

Fig. 2. The curves $\mu = f(\lambda)$ and $\lambda = g(\mu)$ in case (4.18).

satisfies

$$n(0) = 1 + \frac{1}{2}(\ell_1 + m_1) + \frac{1}{4}\ell_1 m_1$$

and, hence, $n(0) < 1$ if $\ell_1 < 0$ and $m_1 < 0$. Thus, if we choose $\ell_1, m_1 \in (-1, 0)$, then, for sufficiently small $\varepsilon > 0$, we have that $n(\varepsilon) < 1$, by continuity, and, consequently, (4.19) holds.

In Fig. 2 we have represented the curves of neutral stability of the semi-trivial states in an admissible situation satisfying (4.18). It should be noted that, for the previous choice, we have that, for each sufficiently small $\varepsilon > 0$,

$$\frac{1}{\beta} = \left(b_0 + \frac{1}{2}b_1 m_1\right)^{-1} = \left(1 - \varepsilon + \frac{1}{2}(1 - 2\varepsilon)m_1\right)^{-1} < c_0 = 1 - \varepsilon < 1$$

and

$$\alpha = c_0 + \frac{1}{2}c_1\ell_1 = 1 - \varepsilon + \frac{1}{2}(1 - 2\varepsilon)\ell_1 > \frac{1}{b_0} = \frac{1}{1 - \varepsilon} > 1$$

since $\ell_1 > 0$ and $m_1 > 0$. As illustrated by Fig. 2, the curves of change of stability of the semi-trivial states must cross at least once, and at most at a finite number of points whose total sum of contact orders must be odd. In the situations described by Fig. 2, one among all admissible ones, these curves divide the first quadrant into four different regions: the two regions enclosed by these curves, and the two exterior regions. In general,

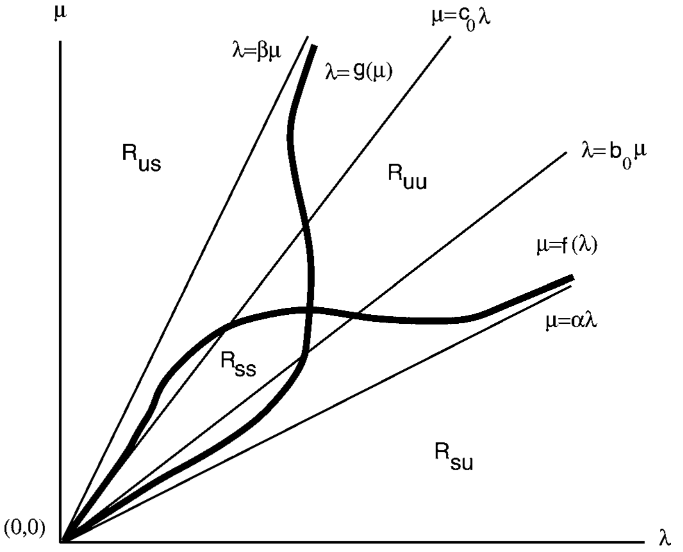

Fig. 3. The curves $\mu = f(\lambda)$ and $\lambda = g(\mu)$ in case (4.19).

the region enclosed between them consists of a finite number of components—one unbounded, and the remaining bounded. Within the bounded components both semi-trivial states are—alternatively—either linearly unstable, or linearly stable. In Fig. 2, both are linearly unstable, because $\mu > f(\lambda)$ and $\lambda > g(\mu)$. Hence, this is the region $\mathrm{R_{uu}}$ defined in (4.1). Independently of the number of bounded components enclosed by the curves of neutral stability of the semi-trivial states, the unbounded component is always a subset of the region $\mathrm{R_{ss}}$ defined in (4.1), where both semi-trivial states are linearly stable. The remaining regions correspond with the regions $\mathrm{R_{su}}$ and $\mathrm{R_{us}}$ defined in (4.2), where one of the semi-trivial states is linearly stable and the other linearly unstable. As in all competing species models, in this example we have that

$$\mathrm{R_{s*}} = (0,\infty)\times(-\infty,0], \quad \mathrm{R_{u*}} = \emptyset,$$
$$\mathrm{R_{*s}} = (-\infty,0]\times(0,\infty), \quad \mathrm{R_{*u}} = \emptyset.$$

In Fig. 3 we have represented an admissible situation adjusted to (4.19) for the choices previously analyzed. Now, for each sufficiently small $\varepsilon > 0$, we have that

$$\alpha := c_0 + \frac{1}{2}c_1\ell_1 = 1+\varepsilon+\frac{1}{2}\ell_1 < \frac{1}{b_0} = \frac{1}{1+\varepsilon} < 1$$

and

$$\frac{1}{\beta} := \left(b_0 + \frac{1}{2}b_1 m_1\right)^{-1} = \left(1+\varepsilon+\frac{1}{2}m_1\right)^{-1} > c_0 = 1+\varepsilon > 1,$$

since $\ell_1 < 0$ and $m_1 < 0$. As the relative positions between the curves of neutral stability of the semi-trivial states suffered a drastic change between the cases sketched in Figs. 2 and 3, in the latest case, within the bounded component enclosed by $\mu = f(\lambda)$ and $\lambda = g(\mu)$ both semi-trivial states must be linearly stable, while in the unbounded component both are linearly unstable. As it is easily realized, this inter-exchange between the relative positions of the curves of neutral stability of the semi-trivial states entails dramatic changes from the point of view of applications.

Although the previous examples exhibit a reminiscent behaviour from the autonomous model for (λ, μ) in a neighborhood of $(0, 0)$, in the sense that, for such range of (λ, μ) *low intensity competition* occurs if $\hat{b}\hat{c} < 1$, while *high intensity competition* occurs if $\hat{b}\hat{c} > 1$, these simple examples illustrate very well how temporal heterogeneities can affect the dynamics of (1.1), as for (λ, μ) sufficiently large the intensity of the competition is measured by α, instead of $\hat{c}$, and β, instead of $\hat{b}$. Actually, for (λ, μ) large, *low intensity competition* occurs if $\alpha\beta < 1$ (cf. Fig. 3), while *high intensity competition* occurs if $\alpha\beta > 1$ (cf. Fig. 2). The observation of this phenomenology goes back to [12].

In the previous examples, a further crossing point, perturbing from $(0, 0)$, might occur if $b_0 c_0 = 1$, as a result of the nature of the second order terms of the asymptotic expansion of (3.3) and (3.6) at $(0, 0)$, but we refrain of performing this sharper analysis here (cf. [13] for the corresponding analysis in the autonomous competing species model with diffusion).

It should be noted that most of the examples treated in the literature did not cover the previous two cases, but, instead, covered some very special situations where the function coefficients were chosen so that the curves of neutral stability of the semi-trivial states cannot meet in the interior of the first quadrant, as in those cases the method of sub- and supersolutions gives the existence of coexistence states in a rather simple way. Most precisely, let $t_L, t_M \in [0, T]$ such that

$$(\theta_{[\lambda\ell,a]})_j = \theta_{[\lambda\ell,a]}(t_j), \quad j \in \{L; M\}.$$

Then, since $\frac{\mathrm{d}\theta_{[\lambda\ell,a]}}{\mathrm{d}t}(t_j) = 0$, we have that

$$\theta_{[\lambda\ell,a]}(t_j) = \frac{\ell(t_j)}{a(t_j)}\lambda, \quad j \in \{L, M\},$$

and, hence,

$$\left(\frac{\ell}{a}\right)_L \lambda \leqslant \theta_{[\lambda\ell,a]} \leqslant \left(\frac{\ell}{a}\right)_M \lambda, \quad \lambda > 0. \tag{4.20}$$

By symmetry,

$$\left(\frac{m}{d}\right)_L \mu \leqslant \theta_{[\mu m,d]} \leqslant \left(\frac{m}{d}\right)_M \mu, \quad \mu > 0. \tag{4.21}$$

Thus, for each $\lambda > 0$,

$$\hat{c}\left(\frac{\ell}{a}\right)_L \lambda \leqslant f(\lambda) = \frac{1}{T}\int_0^T c(t)\theta_{[\lambda\ell,a]}(t)\,\mathrm{d}t \leqslant \hat{c}\left(\frac{\ell}{a}\right)_M \lambda, \tag{4.22}$$

and, for each $\mu > 0$,

$$\hat{b}\left(\frac{m}{d}\right)_L \mu \leqslant g(\mu) = \frac{1}{T}\int_0^T b(t)\theta_{[\mu m,d]}(t)\,\mathrm{d}t \leqslant \hat{b}\left(\frac{m}{d}\right)_M \mu. \tag{4.23}$$

Consequently, the curves of neutral stability (3.3) and (3.6) cannot meet at a point $(\lambda, \mu) \neq (0, 0)$ if either

$$\hat{b}\hat{c}\left(\frac{\ell}{a}\right)_M\left(\frac{m}{d}\right)_M < 1, \tag{4.24}$$

or

$$\hat{b}\hat{c}\left(\frac{\ell}{a}\right)_L\left(\frac{m}{d}\right)_L > 1. \tag{4.25}$$

Actually, in any of these cases the curves $\mu = f(\lambda)$ and $\lambda = g(\mu)$ divide the first quadrant into three regions and, necessarily, either $\mathrm{R}_{\mathrm{ss}} = \emptyset$ or $\mathrm{R}_{\mathrm{uu}} = \emptyset$ (cf. Fig. 4). As in the autonomous model, low intensity competition occurs under (4.24), while high intensity competition occurs if (4.25) is satisfied. It should be noted that (4.24) and (4.25) become into $\hat{b}\hat{c} < 1$ and $\hat{b}\hat{c} > 1$, respectively, if $\ell = a$ and $m = d$. These are the unique two possible situations exhibited by the autonomous model.

Fig. 4. Curves of neutral stability in cases (4.24) (a) and (4.25) (b).

4.2. *The species v preys on u ($b > 0$ and $c < 0$)*

Then, the curves of neutral stability of the semi-trivial states cannot meet at a point $(\lambda, \mu) \neq (0, 0)$, since

$$f(\lambda) = \frac{1}{T} \int_0^T c(t)\theta_{[\lambda\ell,a]}(t)\, \mathrm{d}t < 0 \quad \text{for each } \lambda > 0,$$

and

$$g(\mu) = \frac{1}{T} \int_0^T b(t)\theta_{[\mu m,d]}(t)\, \mathrm{d}t > 0 \quad \text{for each } \mu > 0.$$

Note that, as a consequence from Theorem 2.8, $\lambda \mapsto f(\lambda)$ is decreasing and $\mu \mapsto g(\mu)$ is increasing, since $\ell > 0$ and $m > 0$ (cf. Fig. 5). If we further assume that $\ell \gg 0$, $m \gg 0$, $a \gg 0$ and $d \gg 0$, then, besides the fact that $f(\lambda)$ and $g(\mu)$ are monotone, the tangents to $\mu = f(\lambda)$ and $\lambda = g(\mu)$ at $(0, 0)$ and at infinity are given by the straight lines (4.12) and (4.13), respectively.

Now, the half-plane $\lambda > 0$ is divided into four supplementary regions according to the existence and character of each of the semi-trivial states. The interior of the first quadrant is divided into the two regions R_{us} and R_{uu} (cf. (4.1) and (4.2)), and the quadrant $\lambda > 0$, $\mu \leqslant 0$, where (1.2) exclusively admits the semi-trivial state $(\theta_{[\lambda\ell,a]}, 0)$, is divided into the region $\mu > f(\lambda)$ $\mathrm{R}_{\mathrm{u}*}$, where $(\theta_{[\lambda\ell,a]}, 0)$ is linearly unstable, and the region $\mu < f(\lambda)$ $\mathrm{R}_{\mathrm{s}*}$, where $(\theta_{[\lambda\ell,a]}, 0)$ is linearly stable. Moreover,

$$\mathrm{R}_{*\mathrm{s}} = (-\infty, 0] \times (0, \infty), \quad \mathrm{R}_{*\mathrm{u}} = \emptyset, \quad \mathrm{R}_{\mathrm{ss}} = \emptyset.$$

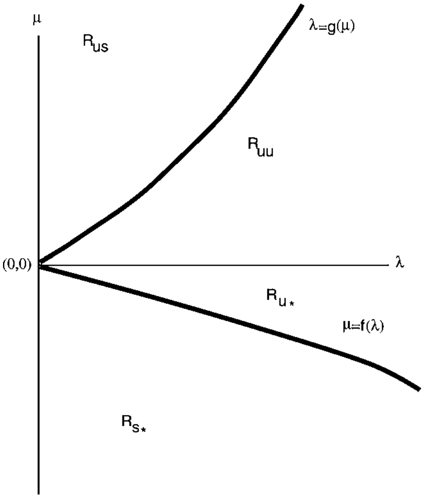

Fig. 5. Curves of neutral stability in the predator-prey model.

The configuration shown by Fig. 5 is reminiscent of the classical one for the autonomous model, where the curves of change of stability of the semi-trivial states $(\lambda, 0)$ and $(0, \mu)$ are $\mu = c\lambda$ and $\lambda = b\mu$, respectively. Actually, if $\ell = a$ and $m = d$, then $\mu = \hat{c}\lambda$ and $\lambda = \hat{b}\mu$ provide us with the tangents at $(0, 0)$ and at infinity to the curves $\mu = f(\lambda)$ and $\lambda = g(\mu)$.

4.3. *The species u and v cooperate (b < 0 and c < 0)*

In this case, $\lambda \mapsto f(\lambda)$ and $\mu \mapsto g(\mu)$ are decreasing and, in general, they look like shows Fig. 6. Now, the regions defined in (4.1)–(4.4) are given by the following identities:

$$\mathrm{R}_{\mathrm{uu}} = (0, \infty) \times (0, \infty), \quad \mathrm{R}_{\mathrm{ss}} = \emptyset, \quad \mathrm{R}_{\mathrm{us}} = \emptyset, \quad \mathrm{R}_{\mathrm{su}} = \emptyset,$$
$$\mathrm{R}_{\mathrm{u}*} = \bigl\{(\lambda, \mu)\colon \lambda > 0,\, f(\lambda) < \mu \leqslant 0\bigr\}, \quad \mathrm{R}_{\mathrm{s}*} = \bigl\{(\lambda, \mu)\colon \lambda > 0,\, \mu < f(\lambda)\bigr\},$$
$$\mathrm{R}_{*\mathrm{u}} = \bigl\{(\lambda, \mu)\colon \mu > 0,\ g(\mu) < \lambda \leqslant 0\}, \quad \mathrm{R}_{*\mathrm{s}} = \{(\lambda, \mu)\colon \mu > 0,\ \lambda < g(\mu)\}.$$

As in the predator-prey model, if we further assume $\ell \gg 0$, $m \gg 0$, $a \gg 0$ and $d \gg 0$, then, besides the fact that $f(\lambda)$ and $g(\mu)$ are monotone, the tangents to the curves of neutral stability $\mu = f(\lambda)$ and $\lambda = g(\mu)$ at $(0, 0)$ and at infinity are given by the straight lines (4.12) and (4.13), respectively. Similarly, the configuration shown by Fig. 6 is reminiscent of the classical one for the autonomous model, where the curves of change of stability of the semi-trivial states $(\lambda, 0)$ and $(0, \mu)$ are $\mu = c\lambda$ and $\lambda = b\mu$, respectively. Actually, if $\ell = a$ and $m = d$, then $\mu = \hat{c}\lambda$ and $\lambda = \hat{b}\lambda$ provide us with the tangents at $(0, 0)$ and at infinity to the curves $\mu = f(\lambda)$ and $\lambda = g(\mu)$.

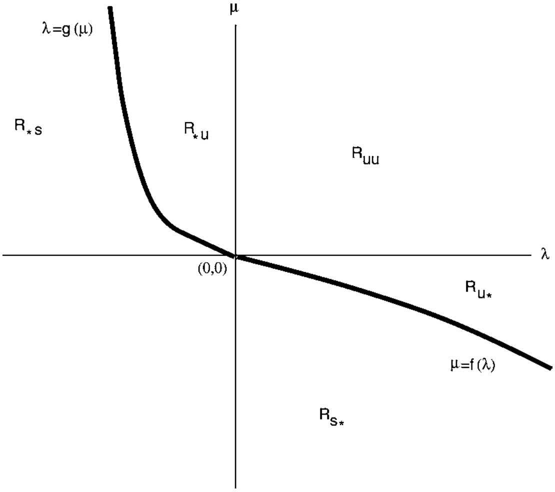

Fig. 6. Curves of neutral stability for the symbiotic model.

4.4. *The general case when b and c change of sign*

As for the competing species model, in order to simplify our analysis, besides (1.7) in this section we assume that

$$a \gg 0, \quad d \gg 0, \quad \ell \gg 0, \quad m \gg 0. \tag{4.26}$$

Then, as in Section 4.1, (4.12) and (4.13) provide us with the tangents at $(0,0)$ and at infinity of the curves of neutral stability of the semi-trivial states. As we are assuming that b and c change of sign in $[0,T]$, we have

$$\begin{aligned} I_+^b &:= \operatorname{Int}\operatorname{supp} b^+ \neq \emptyset, \quad I_-^b := \operatorname{Int}\operatorname{supp} b^- \neq \emptyset, \\ I_+^c &:= \operatorname{Int}\operatorname{supp} c^+ \neq \emptyset, \quad I_-^c := \operatorname{Int}\operatorname{supp} c^- \neq \emptyset, \end{aligned}$$

and, hence, $f(\lambda)$ and $g(\mu)$ fail to be monotone. Nevertheless, since

$$\begin{aligned} \lim_{(c^-)_M \downarrow 0} f(\lambda) &= \frac{1}{T}\int_0^T c^+(t)\theta_{[\lambda\ell,a]}(t)\,\mathrm{d}t, \\ \lim_{(b^-)_M \downarrow 0} g(\mu) &= \frac{1}{T}\int_0^T b^+(t)\theta_{[\mu m,d]}(t)\,\mathrm{d}t, \end{aligned} \tag{4.27}$$

uniformly on compact subsets of (λ,μ), the curves of change of stability of the semi-trivial states approximate the corresponding curves of the competition model with interaction function coefficients b^+ and c^+, as $b^- \downarrow 0$ and $c^- \downarrow 0$. Therefore, on compact subsets of (λ,μ), the regions defined by (4.1) and (4.2) approximate the corresponding regions of the associated competition model. Similarly, since

$$\begin{aligned} \lim_{(c^+)_M \downarrow 0} f(\lambda) &= -\frac{1}{T}\int_0^T c^-(t)\theta_{[\lambda\ell,a]}(t)\,\mathrm{d}t, \\ \lim_{(b^+)_M \downarrow 0} g(\mu) &= -\frac{1}{T}\int_0^T b^-(t)\theta_{[\mu m,d]}(t)\,\mathrm{d}t, \end{aligned} \tag{4.28}$$

uniformly on compact subsets of (λ,μ), the curves of change of stability of the semi-trivial states approximate the corresponding curves of the symbiotic model with interaction function coefficients $-b^-$ and $-c^-$ as $b^+ \downarrow 0$ and $c^+ \downarrow 0$. Consequently, for (λ,μ) varying in any compact subset of $(0,\infty)^2$, the regions defined by (4.1) and (4.2) approximate the corresponding regions of the symbiotic model with interactions $-b^-$ and $-c^-$. Therefore, the general case when b and c change of sign can be regarded as a sort of intermediate situation between a competitive and a symbiotic model. Actually, the map $(B,C):[0,1] \to \mathcal{C}_T \times \mathcal{C}_T$ defined, for each $\varepsilon \in [0,1]$, by

$$\begin{aligned} B(\varepsilon) &:= \varepsilon b^+ - (1-\varepsilon)b^- + 2\varepsilon(1-\varepsilon)\bigl(b^+ - b^-\bigr), \\ C(\varepsilon) &:= \varepsilon c^+ - (1-\varepsilon)c^- + 2\varepsilon(1-\varepsilon)\bigl(c^+ - c^-\bigr), \end{aligned}$$

establishes a homotopy between (b^+, c^+), $(-b^-, -c^-)$ and (b, c). Indeed,

$$\big(B(0), C(0)\big) = \big(-b^-, -c^-\big), \qquad \big(B(1), C(1)\big) = \big(b^+, c^+\big),$$

and

$$\big(B(1/2), C(1/2)\big) = (b, c).$$

Consequently, (1.2) should exhibit an intermediate behavior between those exhibited by a competition and a symbiotic model.

In Fig. 7, we have represented two admissible curves $\mu = f(\lambda)$ and $\lambda = g(\mu)$ in the special case when conditions

$$\hat{b} > 0, \quad \hat{c} > 0, \quad \hat{b}\hat{c} < 1, \tag{4.29}$$

and

$$\alpha := \frac{1}{T}\int_0^T c(t)\frac{\ell(t)}{a(t)}\,\mathrm{d}t < 0, \quad \beta := \frac{1}{T}\int_0^T b(t)\frac{m(t)}{d(t)}\,\mathrm{d}t < 0 \tag{4.30}$$

are satisfied. Conditions (4.29) can be reached by taking b^+ and c^+ with $\hat{b}^+\hat{c}^+ < 1$ and choosing sufficiently small b^- and c^-. In order to get (4.30) it suffices to choose ℓ sufficiently small in I_+^c and m sufficiently small in I_+^b. This entails the birth rate of each of the species must be relatively slow during the time periods where the intensity of its aggressions on the other species reaches its highest level. Consequently, although the species compete, the model exhibits some sort of cooperative behaviour. Nevertheless, one should be very careful in choosing the adequate ranges of values of the parameters where this phenomenology occurs.

For the situation illustrated in Fig. 7, the first quadrant is divided into there regions: the region $\mathrm{R_{uu}}$, where both semi-trivial states are linearly unstable, which is the region where $\mu > f(\lambda)$ and $\lambda > g(\mu)$, the region $\mathrm{R_{su}}$, where $(\theta_{[\lambda\ell,a]}, 0)$ is linearly stable and $(0, \theta_{[\mu m,d]})$ is linearly unstable, which is the region where $\lambda > 0$ and $0 < \mu < f(\lambda)$, and the region $\mathrm{R_{us}}$, where $(\theta_{[\lambda\ell,a]}, 0)$ is linearly unstable and $(0, \theta_{[\mu m,d]})$ is linearly stable, which is given by $\mu > 0$ and $0 < \lambda < g(\mu)$. In the second quadrant ($\lambda \leqslant 0$ and $\mu > 0$), $(0, \theta_{[\mu m,d]})$ is the unique semi-trivial state; it is linearly stable if $\lambda < g(\mu)$ and linearly unstable if $\lambda > g(\mu)$. In the fourth quadrant ($\lambda > 0$ and $\mu \leqslant 0$), $(\theta_{[\lambda\ell,a]})$ is the unique semi-trivial state; it is linearly stable if $\mu < f(\lambda)$ and linearly unstable if $\mu > f(\lambda)$. It should be noted that under conditions (4.29) and (4.30) the curves $\mu = f(\lambda)$ and $\lambda = g(\mu)$ might cross. In such case, their total number of crossing points, counting contact orders, must be even, because $\mu = f(\lambda)$ and $\lambda = g(\mu)$ are real analytic. Also, note that Fig. 7 shows a low-competitive-intensity behaviour around $(\lambda, \mu) = (0, 0)$ and a symbiotic type of behavior for sufficiently large λ and μ.

Now, by choosing b^+ and c^+ such that $\hat{b}^+\hat{c}^+ > 1$, $b^- \sim 0$, $c^- \sim 0$, $\ell \sim 0$ in I_+^c and $m \sim 0$ in I_+^b, one gets

$$\hat{b} > 0, \quad \hat{c} > 0, \quad \hat{b}\hat{c} > 1, \quad \alpha < 0, \quad \beta < 0. \tag{4.31}$$

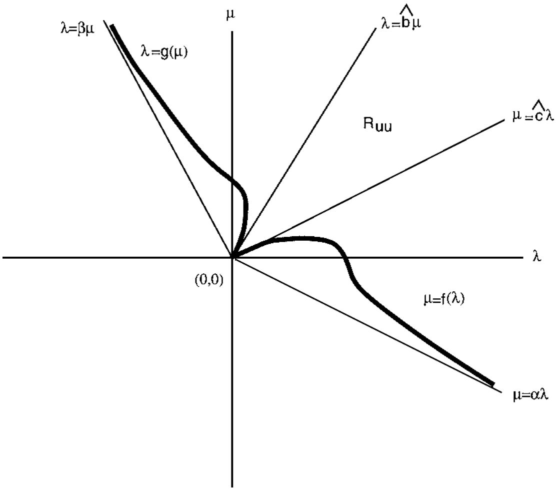

Fig. 7. Curves of neutral stability under conditions (4.29) and (4.30).

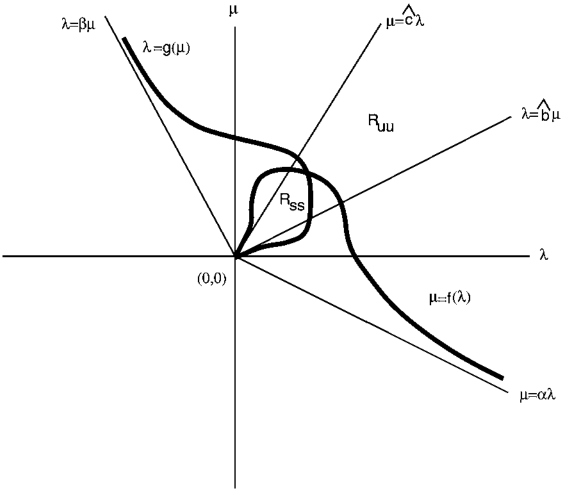

Fig. 8. Curves of neutral stability under condition (4.31).

Fig. 8 shows two admissible curves of neutral stability of semi-trivial states adjusted to (4.31). Now, these curves must cross at an odd number of points, counting contact orders, in such a way that both semi-trivial states are linearly unstable in the unbounded component of the enclosed region between them. Rather naturally, the model exhibits a high-intensity-competition behavior around $(0, 0)$, while it exhibits a genuine cooperative behavior for sufficiently large λ and μ; as far as to the structure of the regions defined in (4.1) and (4.2) concerns. It seems the first occasion that such a kind of behaviour has been observed had been in [22] within the context of reaction diffusion models.

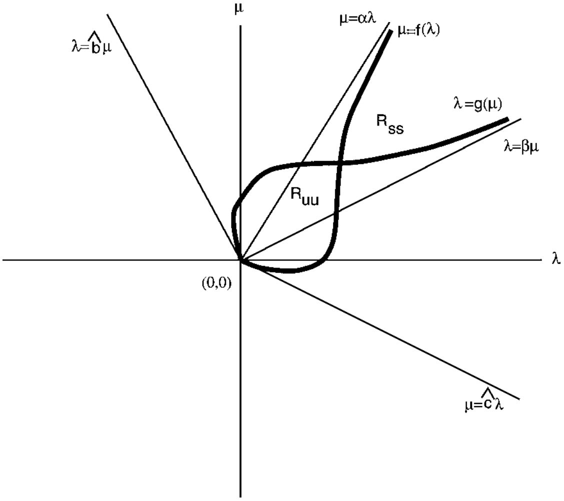

Fig. 9. Curves of neutral stability under condition (4.32).

Now, by choosing sufficiently small b^+ and c^+, $\ell \sim 0$ in I_-^c and sufficiently large in I_+^c, and $m \sim 0$ in I_-^b and sufficiently large in I_+^b, the following conditions can be reached

$$\hat{b} < 0, \quad \hat{c} < 0, \quad \alpha > 0, \quad \beta > 0, \quad \alpha\beta > 1. \tag{4.32}$$

Fig. 9 shows two admissible curves of neutral stability according to (4.32). As in case (4.31), the total number of crossing points between $\mu = f(\lambda)$ and $\lambda = g(\mu)$ must be odd, though, in case (4.32), $\mathrm{R_{ss}}$ includes the unbounded component enclosed by the two curves, while the bounded component containing $(0,0)$ is a subset of $\mathrm{R_{uu}}$, in strong contrast with the situation described by Fig. 8. Actually, in case (4.32), the model exhibits a genuine symbiotic behavior around $(0,0)$, while it possesses a high-intensity-competitive behavior for sufficiently large values of λ and μ.

Finally, by choosing sufficiently small b^- and c^+, one can easily reach

$$\hat{b} > 0, \quad \hat{c} < 0, \quad \alpha < 0, \quad \beta > 0, \tag{4.33}$$

for instance, by taking $\ell = m = a = d = 1$. In such cases the curves $\mu = g(\lambda)$ and $\lambda = g(\mu)$ exhibit a behaviour quite reminiscent of the case when v preys on u (cf. Fig. 10); rather naturally, since these models can be regarded as perturbations from the case when $b^- = 0$ and $c^+ = 0$, where $b > 0$ and $c < 0$—v preys on u—though the symbiotic effects of the interaction might play a significant role for large values of λ and μ. In Fig. 10 we have represented the curves of change of stability of the semi-trivial states of (1.2) in one of the several admissible situation cases.

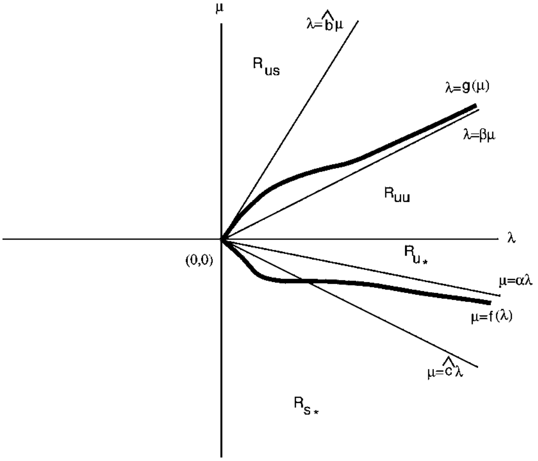

Fig. 10. Curves of neutral stability under condition (4.33).

5. The existence of coexistence states

In this section we are going to give a very general result about the existence of coexistence states of (1.2) for the general case where b and c change of sign. As a matter of fact, our result covers all admissible situations, as we are not imposing any sign restriction on b and c. The general methodology adopted in this section goes back to the pioneering chapter by J.M. Cushing [7], where one of the parameters, λ or μ, was fixed while the other was considered as a bifurcation parameter in order to get the coexistence states as emanating from one of the semi-trivial states in the context of competing species models. This idea has been extremely fruitful in a number of different contexts [19, Chapter 7].

Most precisely, in Section 5.1 we use the abstract unilateral theorem of [19, Chapter 6] to get an abstract global unilateral theorem for systems, which is the basic abstract result to get—as an easy consequence—our theorem about the existence of coexistence states, which will be given in Section 5.2. Our abstract result admits a number of applications in rather different contexts, but we refrain of giving more details here in. It should be noted that the well known, and very celebrated, unilateral theorems of P.H. Rabinowitz [31] are wrong as they are stated. Actually, there is an available—very recent—counterexample by E.N. Dancer [9]. In the subsequent subsections we shall consider each of the possible interactions separately, as in each special circumstance one can obtain sharper consequences from our abstract theorem.

5.1. *Abstract unilateral bifurcation from semi-trivial states*

Let X be an ordered Banach space whose positive cone P is normal and it has nonempty interior, and consider a nonlinear abstract equation of the form

$$\mathfrak{F}(\rho, x, y) := \mathfrak{L}(\rho)(x - x_0, y) + \mathfrak{N}(\rho, x, y) = 0, \quad (\rho, x, y) \in \mathbb{R} \times X^2, \tag{5.1}$$

for some $x_0 \in P \setminus \{0\}$, where

- (HL) $\mathfrak{K}(\rho) := I_{X^2} - \mathfrak{L}(\rho) \in \mathcal{L}(X^2)$, $\rho \in \mathbb{R}$, is a compact and continuous operator pencil with a discrete set of *singular values*, denoted by Σ. Since $\mathfrak{L}(\rho)$ is Fredlhom of index zero, $\sigma \in \Sigma$ if, and only if, σ is an *eigenvalue* of $\mathfrak{L}(\rho)$, i.e., if $\dim N[\mathfrak{L}(\sigma)] \geqslant 1$.
- (HR) $\mathfrak{R} \in \mathcal{C}(\mathbb{R} \times X^2; X^2)$ is compact on bounded sets and

$$\lim_{(x,y)\to(x_0,0)} \frac{\mathfrak{R}(\rho,x,y)}{\|(x-x_0,y)\|} = 0$$

uniformly on compact intervals of $\mathbb{R}$.
- (HP) The solutions of (5.1) satisfy the *strong maximum principle* in the sense that

$$(\rho,x,y) \in \mathbb{R} \times \bigl(P \setminus \{0\}\bigr) \times X \quad \text{and} \quad \mathfrak{F}(\rho,x,y) = 0 \quad \text{imply} \quad x \in \operatorname{Int} P,$$

and

$$(\rho,x,y) \in \mathbb{R} \times X \times \bigl(P \setminus \{0\}\bigr) \quad \text{and} \quad \mathfrak{F}(\rho,x,y) = 0 \quad \text{imply} \quad y \in \operatorname{Int} P,$$

where $\operatorname{Int} P$ stands for the interior of the cone P.

Subsequently, the space X^2 is viewed as an ordered Banach space with positive cone P^2, and, given any ordered Banach space E with positive cone W, and $e_1, e_2 \in E$, we write $e_1 > e_2$ if $e_1 - e_2 \in W \setminus \{0\}$, and $e_1 \gg e_2$ if $e_1 - e_2 \in \operatorname{Int} W$. As

$$\operatorname{Int} P^2 = \operatorname{Int} P \times \operatorname{Int} P,$$

it is said that (ρ,x,y) is a *positive solution* of (5.1), if (ρ,x,y) is a solution of (5.1) with $(x,y) > 0$ ($x \geqslant 0$, $y \geqslant 0$ and $(x,y) \neq (0,0)$). Thanks to Hypothesis (HP), any positive solution (ρ,x,y) of (5.1) must have one of the following forms: either $x \gg 0$ and $y \gg 0$—*strongly positive*, or $x \gg 0$ and $y = 0$, or $x = 0$ and $y \gg 0$—*semi-trivial positive solutions*.

Under Hypotheses (HL) and (HR),

$$\mathfrak{F}(\rho,x_0,0) = 0 \quad \text{for each } \rho \in \mathbb{R}, \tag{5.2}$$

and, due to Hypothesis (HP), $x_0 \gg 0$, since $x_0 > 0$. Moreover, since $\mathfrak{L}(\rho)$ is a linear isomorphism for any $\rho \in \mathbb{R} \setminus \Sigma$, the *fixed point index*

$$\operatorname{Ind}\bigl(0, \mathfrak{K}(\rho)\bigr)$$

is well defined—the topological degree of $\mathfrak{L}(\rho)$ in any bounded open set containing 0. Thus, the following *crossing number* $C : \Sigma \to \{-1,0,1\}$ can be introduced

$$C(\sigma) := \frac{1}{2} \lim_{\varepsilon \downarrow 0} \bigl[\operatorname{Ind}\bigl(0, \mathfrak{K}(\sigma+\varepsilon)\bigr) - \operatorname{Ind}\bigl(0, \mathfrak{K}(\sigma-\varepsilon)\bigr)\bigr], \quad \sigma \in \Sigma. \tag{5.3}$$

Note that $C(\sigma) \neq 0$ if, and only if, $\operatorname{Ind}(0, \mathfrak{K}(\rho))$ changes as ρ crosses σ, and that this occurs if, and only if, $\operatorname{Ind}((x_0, 0), \mathfrak{F}(\rho, \cdot, \cdot))$ changes as ρ crosses σ.

Our main result concerns the bounded components of strongly positive solutions of (5.1) emanating from the curve $(\rho, x, y) = (\rho, x_0, 0)$ at a singular value $\rho_0 \in \Sigma$ with—classical—geometric multiplicity one and $C(\rho_0) \in \{-1, 1\}$. By a *component* of strongly positive solutions of (5.1) it is meant a maximal (for the inclusion) relatively closed and connected subset of the set of strongly positive solutions of (5.1)—in $\mathbb{R} \times \operatorname{Int} P^2$. Thanks to [19, Theorem 6.2.1], Eq. (5.1) possesses a component emanating from $(\rho, x, y) = (\rho, x_0, 0)$ at ρ_0 if $C(\rho_0) \in \{-1, 1\}$. Such a component will be subsequently denoted by $\mathfrak{C}_0$. Throughout the remaining of this section, we shall denote by P_x and P_y the projection operators

$$P_x(x, y) = x, \quad P_y(x, y) = y, \quad (x, y) \in X^2. \tag{5.4}$$

The main abstract result of this section can now be stated as follows.

THEOREM 5.1. *Suppose $\rho_0 \in \Sigma$ satisfies $C(\rho_0) \neq 0$,*

$$N\big[\mathfrak{L}(\rho_0)\big] = \operatorname{span}\big[(\varphi_{0x}, \varphi_{0y})\big], \quad \varphi_{0y} \in P \setminus \{0\}, \tag{5.5}$$

and, for each $x \in X$, $P_y\mathfrak{K}(\rho_0)(x, \cdot)$ is strongly positive, in the sense that

$$P_y\mathfrak{K}(\rho_0)(x, \cdot)\big(P \setminus \{0\}\big) \subset \operatorname{Int} P. \tag{5.6}$$

Then,

$$\operatorname{spr} P_y\mathfrak{K}(\rho_0)(\varphi_{0x}, \cdot) = 1 \tag{5.7}$$

and there exists a component $\mathfrak{C}_0^P$ of $\mathfrak{C}_0 \cap [\mathbb{R} \times (\operatorname{Int} P)^2]$ such that

$$(\rho_0, x_0, 0) \in \bar{\mathfrak{C}}_0^P.$$

Suppose, in addition, that $\mathfrak{C}_0^P$ is bounded in $\mathbb{R} \times X^2$ and that

$$\operatorname{spr} P_y\mathfrak{K}(\rho_0)(x, \cdot) = 1 \quad \textit{for each } x \in X. \tag{5.8}$$

Then, some of the following alternatives occurs:

A1. *There exists $(\rho_1, x_1) \in (\mathbb{R} \times P) \setminus \{(\rho_0, x_0)\}$ such that $(\rho_1, x_1, 0) \in \bar{\mathfrak{C}}_0^P$. In such case, thanks to* (HP), *$x_1 \gg 0$ if $x_1 > 0$.*

A2. *There exists $(\rho_1, y_1) \in \mathbb{R} \times P$ such that $(\rho_1, 0, y_1) \in \bar{\mathfrak{C}}_0^P$. In such case, thanks to* (HP), *$y_1 \gg 0$ if $y_1 > 0$.*

Furthermore, alternative A2 *occurs if $(\rho, x, 0) \in \mathfrak{F}^{-1}(0)$ implies $x = x_0$, and ρ_0 is the unique value of ρ for which one is an eigenvalue of $P_y\mathfrak{K}(\rho)(x_0, \cdot)$ to a positive eigenvector.*

PROOF. The set of *non-trivial solutions* of (5.1) is defined through

$$\mathfrak{S} := \mathfrak{F}^{-1}\big((0,0)\big) \setminus \big[(\mathbb{R} \setminus \Sigma) \times \big\{(x_0, 0)\big\}\big]. \tag{5.9}$$

Note that $(\rho, x, y) \in \mathfrak{S}$ if $\mathfrak{F}(\rho, x, y) = 0$ with $(x, y) \neq (x_0, 0)$, or $(\rho, x, y) = (\rho, x_0, 0)$ with $\rho \in \Sigma$. Since $C(\rho_0) \neq 0$, thanks to [19, Theorem 6.2.1] there exists a component of $\mathfrak{S}$, denoted by $\mathfrak{C}_0$, such that $(\rho_0, x_0, 0) \in \mathfrak{C}_0$. Subsequently, we suppose that

$$\varphi_0 := (\varphi_{0x}, \varphi_{0y}) \in X \times \operatorname{Int} P$$

has been normalized so that

$$\|\varphi_0\|_{X^2} = 1.$$

It should be noted that, thanks to (HL),

$$\mathfrak{K}(\rho_0)\varphi_0 = \varphi_0$$

and, hence,

$$P_y \mathfrak{K}(\rho_0)(\varphi_{0x}, \varphi_{0y}) = \varphi_{0y}.$$

Thus, it follows from (5.5) and (5.6) that $\varphi_{0y} \gg 0$. Moreover, thanks to (5.6), (5.7) is a consequence from Krein–Rutman theorem, since the spectral radius is the unique real eigenvalue associated with it there is a positive eigenvector.

Now, let Z be a closed subspace of X^2 such that

$$X^2 = N\big[\mathfrak{L}(\rho_0)\big] \oplus Z.$$

Thanks to Hahn–Banach's theorem, there exists

$$\varphi_0^* := \big(\varphi_{0x}^*, \varphi_{0y}^*\big) \in X' \times X'$$

for which

$$Z = \big\{(x, y) \in X^2 \colon \big\langle \varphi_0^*, (x, y)\big\rangle = 0\big\}, \quad \big\langle \varphi_0^*, \varphi_0\big\rangle = 1,$$

where $\langle \cdot, \cdot \rangle$ stands for the duality between X^2 and $X' \times X'$. Now, adapting the theory developed by P.H. Rabinowitz [31], for each $\eta \in (0, 1)$ and sufficiently small $\varepsilon > 0$ we set

$$\begin{aligned} \mathcal{Q}_{\varepsilon,\eta} := \big\{&(\rho, x, y) \in \mathbb{R} \times X^2 \colon |\rho - \rho_0| < \varepsilon, \\ &\big|\big\langle \varphi_0^*, (x - x_0, y)\big\rangle\big| > \eta \big\|(x - x_0, y)\big\|\big\}. \end{aligned}$$

Since the mapping

$$(x, y) \mapsto \big|\big\langle \varphi_0^*, (x - x_0, y)\big\rangle\big| - \eta \big\|(x - x_0, y)\big\|$$

is continuous, $\mathcal{Q}_{\varepsilon,\eta}$ is an open subset of $\mathbb{R}\times X^2$ consisting of the two disjoint components $\mathcal{Q}^+_{\varepsilon,\eta}$ and $\mathcal{Q}^-_{\varepsilon,\eta}$ defined through

$$\begin{aligned}\mathcal{Q}^+_{\varepsilon,\eta} &:= \big\{(\rho,x,y)\in\mathbb{R}\times X^2\colon\ |\rho-\rho_0|<\varepsilon,\\ &\qquad \big\langle\varphi_0^*,(x-x_0,y)\big\rangle>\eta\big\|(x-x_0,y)\big\|\big\},\\ \mathcal{Q}^-_{\varepsilon,\eta} &:= \big\{(\rho,x,y)\in\mathbb{R}\times X^2\colon\ |\rho-\rho_0|<\varepsilon,\\ &\qquad \big\langle\varphi_0^*,(x-x_0,y)\big\rangle<-\eta\big\|(x-x_0,y)\big\|\big\}.\end{aligned}$$

The following result collects the main consequences from [19, Theorem 6.2.1, Lemma 6.4.1, Proposition 6.4.2]; it is entirely attributable to P.H. Rabinowitz [31].

THEOREM 5.2. *For each sufficiently small* $\delta>0$,

$$\mathfrak{C}_0\cap B_\delta(\rho_0,x_0,0)\subset\mathcal{Q}_{\varepsilon,\eta}\cup\big\{(\rho_0,x_0,0)\big\}$$

and each of the sets

$$\mathfrak{S}\setminus\big[\mathcal{Q}^-_{\varepsilon,\eta}\cap B_\delta(\rho_0,x_0,0)\big]\quad\textit{and}\quad\mathfrak{S}\setminus\big[\mathcal{Q}^+_{\varepsilon,\eta}\cap B_\delta(\rho_0,x_0,0)\big]$$

contains a component, denoted by $\mathfrak{C}_0^+$ *and* $\mathfrak{C}_0^-$, *respectively, such that*

$$(\rho_0,x_0,0)\in\mathfrak{C}_0^+\cap\mathfrak{C}_0^-$$

and

$$\mathfrak{C}_0\cap B_\delta(\rho_0,x_0,0)=\big(\mathfrak{C}_0^+\cup\mathfrak{C}_0^-\big)\cap B_\delta(\rho_0,x_0,0).\tag{5.10}$$

Moreover, for each

$$(\rho,x,y)\in\big[\mathfrak{C}_0\setminus\big\{(\rho_0,x_0,0)\big\}\big]\cap B_\delta(\rho_0,x_0,0),$$

there exists a unique $(s,\tilde{x},\tilde{y})\in\mathbb{R}\times Z$ *such that* $\rho=\rho(s)$ *and*

$$(x,y)=(x_0,0)+s\varphi_0+\big(\tilde{x},\tilde{y}\big)=\big(x_0+s\varphi_{0x}+\tilde{x},s\varphi_{0y}+\tilde{y}\big)\tag{5.11}$$

with $|s|>\eta\,\|(x-x_0,y)\|$. *Actually,*

$$\rho=\rho_0+\mathrm{o}(1)\quad\textit{and}\quad\big(\tilde{x},\tilde{y}\big)=\mathrm{o}(s),\quad\textit{as } s\to 0.\tag{5.12}$$

Note that if

$$(\rho,x,y)\in\mathfrak{C}_0^+\cap B_\delta(\rho_0,x_0,0),\quad (x,y)\neq(x_0,0),$$

then (5.11) holds with $s > \eta \,\|(x - x_0, y)\| > 0$ and, hence,

$$s^{-1} y = \varphi_{0y} + s^{-1}\tilde{y}.$$

Thus, due to (5.12), for sufficiently small $s > 0$ we have that $s^{-1}y \in \operatorname{Int} P$, since $\varphi_{0y} \gg 0$, and, hence, $y \gg 0$. The fact that $x \gg 0$ is an easy consequence from (5.12) and the fact that $x_0 \gg 0$. Therefore, for any sufficiently small $\delta > 0$ we have that

$$\big[\mathfrak{C}_0^+ \setminus \big\{(\rho_0, x_0, 0)\big\}\big] \cap B_\delta(\rho_0, x_0, 0) \subset \mathbb{R} \times \operatorname{Int} P^2. \tag{5.13}$$

This shows the existence of the component $\mathfrak{C}_0^P$. Actually, $\mathfrak{C}_0^P$ is the maximal sub-continuum of $\mathfrak{C}_0^+$ in $\mathbb{R} \times \operatorname{Int} P^2$ such that

$$(\rho_0, x_0, 0) \in \bar{\mathfrak{C}}_0^P.$$

If $\mathfrak{C}_0^P$ is unbounded in $\mathbb{R} \times X^2$ the proof is concluded. So, for the remaining of the proof we will assume that $\mathfrak{C}_0^P$ is bounded.

The following result, which is [19, Theorem 6.4.3], provides us with an updated version of the very celebrated unilateral theorem of P.H. Rabinowitz [31, Theorem 1.27] which is necessary to conclude the proof of Theorem 5.1. It should be noted that [31, Theorem 1.27] is wrong as originally stated (cf. the detailed discussion carried out in [19, p. 180] and the counterexample of E.N. Dancer [9]).

THEOREM 5.3. *The component $\mathfrak{C}_0^+$ satisfies some of the following alternatives*:

1. $\mathfrak{C}_0^+$ *is unbounded in* $\mathbb{R} \times X^2$.
2. *There exists* $\rho_1 \in \Sigma \setminus \{\rho_0\}$ *such that* $(\rho_1, x_0, 0) \in \mathfrak{C}_0^+$.
3. *There exists* $(\rho, x, y) \in \mathfrak{C}_0^+$ *such that*

$$(\rho, x - x_0, y) \in \mathbb{R} \times \big(Z \setminus \{0\}\big).$$

Now, we shall prove that

$$X^2 = N\big[\mathfrak{L}(\rho_0)\big] \oplus R\big[\mathfrak{L}(\rho_0)\big]. \tag{5.14}$$

Since $\mathfrak{L}(\rho_0)$ is Fredholm of index zero, to show (5.14) it suffices to prove that $\varphi_0 \notin R[\mathfrak{L}(\rho_0)]$. This will be accomplished by contradiction. Suppose, there exists $(x, y) \in X^2$ such that

$$\mathfrak{L}(\rho_0)(x, y) = (x, y) - \mathfrak{K}(\rho_0)(x, y) = \varphi_0 = (\varphi_{0x}, \varphi_{0y}).$$

Then,

$$y - P_y \mathfrak{K}(\rho_0)(x, y) = \varphi_{0y} \gg 0. \tag{5.15}$$

Note that, thanks to (HL) and (5.6), the map

$$y \mapsto P_y\mathfrak{K}(\rho_0)(x, y)$$

defines a linear compact strongly order preserving operator. Moreover, by construction,

$$P_y\mathfrak{K}(\rho_0)(\varphi_{0x}, \varphi_{0y}) = \varphi_{0y}$$

and, due to (5.8),

$$\operatorname{spr} P_y\mathfrak{K}(\rho_0)(x, \cdot) = 1.$$

Let $\psi_x \gg 0$ denote the principal eigenfunction associated to $P_y\mathfrak{K}(\rho_0)(x, \cdot)$. Then, thanks to (5.15), for each $\beta > 0$ we have that

$$y + \beta\psi_x - P_y\mathfrak{K}(\rho_0)(x, y + \beta\psi_x) = \varphi_{0y}.$$

On the other hand, since

$$\lim_{\beta\uparrow\infty} \left(\beta^{-1}y + \psi_x\right) = \psi_x \gg 0,$$

it is apparent that, for each sufficiently large $\beta > 0$, one has that

$$y + \beta\psi_x \gg 0$$

provides us with a positive solution of (5.15). Thanks to H. Amann [4, Theorem 3.2], this is impossible. This contradiction concludes the proof of (5.14). Consequently, in order to apply Theorem 5.3, we can make the special choice

$$Z = R\left[\mathfrak{L}(\rho_0)\right], \tag{5.16}$$

which will be maintained throughout the rest of the proof.

Since $\mathfrak{C}_0^P \subset \mathfrak{C}_0^+$, some of the following alternatives occurs: either

$$\mathfrak{C}_0^P = \mathfrak{C}_0^+ \setminus \left\{(\rho_0, x_0, 0)\right\}, \tag{5.17}$$

or

$$\mathfrak{C}_0^P \text{ is a proper subset of } \mathfrak{C}_0^+ \setminus \left\{(\rho_0, x_0, 0)\right\}. \tag{5.18}$$

Suppose (5.17). Then, $\bar{\mathfrak{C}}_0^P = \mathfrak{C}_0^+$ satisfies some of the alternatives of Theorem 5.3. Alternative 1 cannot be satisfied, since $\bar{\mathfrak{C}}_0^P$ is compact. Suppose alternative 3 occurs. Then, thanks to the choice (5.16), there exists

$$(\rho, x, y) \in \mathfrak{C}_0^+ = \bar{\mathfrak{C}}_0^P \subset \mathbb{R} \times P^2$$

such that

$$(\rho, x - x_0, y) \in \mathbb{R} \times R\big[\mathfrak{L}(\rho_0)\big], \quad y \neq 0.$$

Since $(\rho, x, y) \in \mathbb{R} \times P^2$ with $y \neq 0$, necessarily $y > 0$ and, consequently, $y \gg 0$, by (HP). Thus, there exists $(\tilde{x}, \tilde{y}) \in X^2$ such that

$$\mathfrak{L}(\rho_0)(\tilde{x}, \tilde{y}) = (\tilde{x}, \tilde{y}) - \mathfrak{K}(\rho_0)(\tilde{x}, \tilde{y}) = (x - x_0, y)$$

and, taking projections,

$$\tilde{y} - P_y\mathfrak{K}(\rho_0)\big(\tilde{x}, \tilde{y}\big) = y \gg 0.$$

Arguing as above, this is impossible, because, due to (5.8),

$$\operatorname{spr} P_y\mathfrak{K}(\rho_0)(\tilde{x}, \cdot) = 1.$$

Thus, alternative 2 of Theorem 5.3 must be satisfied. Consequently, there exists $\rho_1 \in \Sigma \setminus \{\rho_0\}$ such that

$$(\rho_1, x_0, 0) \in \mathfrak{C}_0^+ = \bar{\mathfrak{C}}_0^P$$

and, therefore, alternative A1 of the theorem is satisfied.

Now, suppose (5.18), instead of (5.17). Then, since

$$\mathfrak{C}_0^+ \cap B_\delta(\rho_0, x_0, 0) = \big[\mathfrak{C}_0^P \cap B_\delta(\rho_0, x_0, 0)\big] \cup \big\{(\rho_0, x_0, 0)\big\}$$

for each sufficiently small $\delta > 0$, fixing one of these δ's, there exists

$$(\rho_1, x_1, y_1) \notin B_\delta(\rho_0, x_0, 0) \tag{5.19}$$

such that

$$(\rho_1, x_1, y_1) \in \mathfrak{C}_0^+ \cap \big(\mathbb{R} \times \partial P^2\big) \cap \partial\mathfrak{C}_0^P,$$

where, given any set U, ∂U stands for the boundary of U. Then,

$$\mathfrak{F}(\rho_1, x_1, y_1) = 0 \quad \text{and} \quad (x_1, y_1) \in P^2.$$

If $x_1 > 0$ and $y_1 > 0$, then, due to (HP), $x_1 \gg 0$ and $y_1 \gg 0$, which is impossible, since $(x_1, y_1) \in \partial P^2$. Thus, either $x_1 = 0$, or $y_1 = 0$. Suppose $y_1 = 0$. Then, thanks to (5.19), $(\rho_1, x_1) \neq (\rho_0, x_0)$, and, therefore, alternative A1 is satisfied again. Obviously, if $x_1 = 0$, then the alternative A2 is satisfied.

Finally, suppose that $(\rho, x, 0) \in \mathfrak{F}^{-1}(0)$ implies $x = x_0$, and ρ_0 is the unique value of ρ for which one is an eigenvalue of $P_y\mathfrak{K}(\rho)(x_0, \cdot)$ to a positive eigenvector. To conclude the proof of the theorem we proceed by contradiction. Assume alternative A1 is satisfied. Then, there exists $(\rho_1, x_1) \in (\mathbb{R} \times P) \setminus \{(\rho_0, x_0)\}$ such that $(\rho_1, x_1, 0) \in \bar{\mathfrak{C}}_0^P$. Thus, $x_1 = x_0$, since $(\rho_1, x_1, 0) \in \mathfrak{F}^{-1}(0)$, and, hence,

$$\rho_1 \neq \rho_0. \tag{5.20}$$

Let $\{(\gamma_n, u_n, v_n)\}_{n\geqslant 1}$ be any subsequence of $\mathfrak{C}_0^P$ such that

$$\lim_{n\to\infty} (\gamma_n, u_n, v_n) = (\rho_1, x_0, 0). \tag{5.21}$$

Then, for each $n \geqslant 1$, $v_n \gg 0$, and, setting,

$$\psi_n := \frac{v_n}{\|v_n\|},$$

we find from $\mathfrak{F}(\gamma_n, u_n, v_n) = 0$ that

$$\begin{aligned}\psi_n &= P_y\mathfrak{K}(\gamma_n)(u_n, \psi_n) - \frac{P_y\mathfrak{R}(\gamma_n, u_n, v_n)}{\|v_n\|}\\ &= P_y\mathfrak{K}(\rho_1)(u_n, \psi_n) + P_y\big[\mathfrak{K}(\gamma_n) - \mathfrak{K}(\rho_1)\big](u_n, \psi_n) - \frac{P_y\mathfrak{R}(\gamma_n, u_n, v_n)}{\|v_n\|}.\end{aligned}$$

As $\{(u_n, \psi_n)\}_{n\geqslant 1}$ is bounded, since we are assuming that $\mathfrak{C}_0^P$ is bounded, we have

$$\lim_{n\to\infty} P_y\big[\mathfrak{K}(\gamma_n) - \mathfrak{K}(\rho_1)\big](u_n, \psi_n) = 0,$$

by the continuity of $\mathfrak{K}(\rho)$ in ρ. Moreover, thanks to (5.21), it follows from (HR) that

$$\lim_{n\to\infty} \frac{P_y\mathfrak{R}(\gamma_n, u_n, v_n)}{\|v_n\|} = 0.$$

Thus, for each $n \geqslant 1$, there exists $w_n \in X$ such that

$$\psi_n = P_y\mathfrak{K}(\rho_1)(x_0, \psi_n) + w_n$$

with $\lim_{n\to\infty} w_n = 0$. Consequently, by compactness, there exists a subsequence of $\{\psi_n\}_{n\geqslant 1}$, again labeled by n, for which the limit

$$\Psi := \lim_{n\to\infty} \psi_n \in X$$

exists and it satisfies

$$\Psi = P_y\mathfrak{K}(\rho_1)(x_0, \Psi). \tag{5.22}$$

Necessarily $\Psi \in P$ and $\|\Psi\| = 1$. Thus, $\Psi > 0$ and, hence, Ψ provides us with a positive eigenvector of $P_y\mathfrak{K}(\rho_1)(x_0, \cdot)$ associated with the eigenvalue 1. By our assumptions, this is impossible, unless $\rho_1 = \rho_0$, which contradicts (5.20). This concludes the proof. □

5.2. *The existence of coexistence states in the general case*

Subsequently, we fix $\lambda > 0$ and consider μ as the main bifurcation parameter. Also, $X := \mathcal{C}_T$ will be regarded as an ordered Banach space by its cone of non-negative functions, P. Note that P is normal, since every order interval is bounded. Also, note that, given any constant $M > 0$—to be chosen later—$(u, v) \in \mathcal{C}^1_T \times \mathcal{C}^1_T$ is a solution of (1.2) if and only if,

$$(u, v) \in \mathcal{C}_T \times \mathcal{C}_T \quad \text{and} \quad \mathfrak{F}(\mu, u, v) = 0, \tag{5.23}$$

where

$$\mathfrak{F} : \mathbb{R} \times \mathcal{C}_T \times \mathcal{C}_T \to \mathcal{C}_T \times \mathcal{C}_T$$

is the operator defined by

$$\mathfrak{F}(\mu, u, v) := \begin{pmatrix} u - \mathfrak{R}_M\big[(\lambda\ell + M)u - au^2 - buv\big] \\ v - \mathfrak{R}_M\big[(\mu m + M)v - dv^2 - cuv\big] \end{pmatrix} \tag{5.24}$$

and $\mathfrak{R}_M$ stands for the operator introduced in (2.10),

$$\mathfrak{R}_M := J\left(\frac{\mathrm{d}}{\mathrm{d}t} + M\right)^{-1} : \mathcal{C}_T \to \mathcal{C}_T.$$

Thanks to Proposition 2.1, $\mathfrak{R}_M$ is compact and strongly order preserving. Moreover, for each $\mu \in \mathbb{R}$ we have that

$$\mathfrak{F}(\mu, \theta_{[\lambda\ell, a]}, 0) = 0$$

and, hence, since $\mathfrak{F}$ is real analytic, the general assumptions (HL) and (HR) of Section 5.1 are satisfied by choosing

$$(\rho, x_0, 0) := (\mu, \theta_{[\lambda\ell, a]}, 0), \qquad \mu \in \mathbb{R}. \tag{5.25}$$

Moreover, if $\mathfrak{F}(\mu, u, v) = 0$ with $u(t_0) > 0$ for some $t_0 \in \mathbb{R}$, then

$$u(t) = \mathrm{e}^{\int_{t_0}^{t} (\lambda\ell - au - bv)} u(t_0) > 0$$

for each $t \in \mathbb{R}$, since

$$u' = (\lambda\ell - au - bv)u,$$

and, hence, $u \gg 0$. Similarly, $v \gg 0$ if it is somewhere positive. Therefore, $\mathfrak{F}$ satisfies Hypothesis (HP) as well.

Maintaining the notations introduced in Section 5.1, for the choice (5.25) we have that the linearization

$$\mathfrak{L}(\mu) := D_{(u,v)}\mathfrak{F}(\mu, \theta_{[\lambda\ell,a]}, 0)$$

is given, for each $(u, v) \in \mathcal{C}_T \times \mathcal{C}_T$, through

$$\mathfrak{L}(\mu)\begin{pmatrix} u \\ v \end{pmatrix} := \begin{pmatrix} u - \mathfrak{R}_M\big[(\lambda\ell + M - 2a\theta_{[\lambda\ell,a]})u - b\theta_{[\lambda\ell,a]}v\big] \\ v - \mathfrak{R}_M\big[(\mu m + M - c\theta_{[\lambda\ell,a]})v\big] \end{pmatrix} \tag{5.26}$$

and, therefore,

$$\mathfrak{K}(\mu)\begin{pmatrix} u \\ v \end{pmatrix} := \begin{pmatrix} \mathfrak{R}_M\big[(\lambda\ell + M - 2a\theta_{[\lambda\ell,a]})u - b\theta_{[\lambda\ell,a]}v\big] \\ \mathfrak{R}_M\big[(\mu m + M - c\theta_{[\lambda\ell,a]})v\big] \end{pmatrix}.$$

Suppose $(u, v) \in N[\mathfrak{L}(\mu)]$ for some $\mu \in \mathbb{R}$ and $(u, v) \neq (0, 0)$. Then, $u, v \in \mathcal{C}^1_T$, and

$$\begin{cases} u' = (\lambda\ell - 2a\theta_{[\lambda\ell,a]})u - b\theta_{[\lambda\ell,a]}v, \\ v' = (\mu m - c\theta_{[\lambda\ell,a]})v. \end{cases} \tag{5.27}$$

Suppose $v = 0$. Then, $u \neq 0$ and the second equation of (5.27) holds true. Moreover, the first one reduces to

$$u' = (\lambda\ell - 2a\theta_{[\lambda\ell,a]})u. \tag{5.28}$$

Thanks to (2.28), we have that

$$\int_0^T (\lambda\ell - a\theta_{[\lambda\ell,a]}) = 0$$

and, hence,

$$\int_0^T (\lambda\ell - 2a\theta_{[\lambda\ell,a]}) = -\int_0^T a(t)\theta_{[\lambda\ell,a]}(t)\,\mathrm{d}t < 0. \tag{5.29}$$

Therefore, (5.28) cannot admit a non-trivial T-periodic solution. This contradiction shows that, necessarily, $v \neq 0$, which implies

$$\mu = \mu_0 := \frac{1}{T}\int_0^T c(t)\theta_{[\lambda\ell,a]}(t)\,\mathrm{d}t, \tag{5.30}$$

since $\hat{m} = 1$. Actually, in this case, there exists a constant $A \neq 0$ such that

$$v = A\varphi_v, \quad \varphi_v(t) := \mathrm{e}^{\int_0^t (\mu_0 m - c\theta_{[\lambda\ell,a]})}, \ t \in \mathbb{R}. \tag{5.31}$$

Thanks to (5.29), it follows from Proposition 2.1 that the problem

$$u' = (\lambda\ell - 2a\theta_{[\lambda\ell,a]})u - b\theta_{[\lambda\ell,a]}\varphi_v, \quad u \in \mathcal{C}_T^1, \tag{5.32}$$

possesses a unique solution. Namely,

$$\varphi_u := -\mathfrak{R}_{2a\theta_{[\lambda\ell,a]}-\lambda\ell}(b\theta_{[\lambda\ell,a]}\varphi_v). \tag{5.33}$$

Consequently, $\mathfrak{L}(\mu)$ is an isomorphism if $\mu \neq \mu_0$, whereas

$$N\big[\mathfrak{L}(\mu_0)\big] = \operatorname{span}\big[(\varphi_u, \varphi_v)\big]. \tag{5.34}$$

In particular, using the notations introduced in Section 5.1, this entails $\Sigma = \{\mu_0\}$. Note that, since $\varphi_v \gg 0$, condition (5.5) is satisfied. Also, for each $u, v \in X = \mathcal{C}_T$, we have that

$$P_v\mathfrak{K}(\mu_0)(u, v) = \mathfrak{R}_M\big[(\mu_0 m + M - c\theta_{[\lambda\ell,a]})v\big], \tag{5.35}$$

which is independent of u. Now, choosing M sufficiently large so that

$$\mu_0 m + M - c\theta_{[\lambda\ell,a]} \gg 0,$$

it follows from Proposition 2.1 that $P_v\mathfrak{K}(\mu_0)(u, v) \gg 0$ if $v > 0$. Therefore, (5.6) and (5.7) are satisfied. Actually, since $P_v\mathfrak{K}(\mu_0)(u, \cdot)$ is constant in u, condition (5.8) is as well satisfied. Furthermore, since $(\theta_{[\lambda\ell,a]}, 0)$ is the unique semi-trivial solution of (1.2) for each $\mu \in \mathbb{R}$ and 1 cannot be an eigenvalue of $P_v\mathfrak{K}(\mu)(0, \cdot)$, unless $\mu = \mu_0$—we have already seen it in the proof of (5.34)—to show that all assumptions of Theorem 5.1 are satisfied it remains to prove that $C(\mu_0) \neq 0$. To prove it, one can argue as follows. Note that $\mathfrak{L}(\mu)$ is analytic in μ and that, for each $u, v \in \mathcal{C}_T$, we have

$$\frac{\mathrm{d}\mathfrak{L}}{\mathrm{d}\mu}(\mu)(u, v) = \big(0, -\mathfrak{R}_M(mv)\big).$$

We now show that the following holds:

$$\frac{\mathrm{d}\mathfrak{L}}{\mathrm{d}\mu}(\mu_0)(\varphi_u, \varphi_v) = \big(0, -\mathfrak{R}_M(m\varphi_v)\big) \notin R\big[\mathfrak{L}(\mu_0)\big]. \tag{5.36}$$

Indeed, if (5.36) is not true, then there exists $v \in \mathcal{C}_T$ such that

$$-\mathfrak{R}_M(m\varphi_v) = v - \mathfrak{R}_M\big[(\mu_0 m + M - c\theta_{[\lambda\ell,a]})v\big].$$

Equivalently,

$$v' = (\mu_0 m - \theta_{[\lambda\ell,a]})v - m\varphi_v, \quad v \in \mathcal{C}_T. \tag{5.37}$$

Thanks to (5.30), it follows from Proposition 2.1(d) that (5.37) does not admit a solution, since $m\varphi_v > 0$. This contradiction shows (5.36). It should be noted that (5.36) is the classical transversality condition of M.G. Crandall and P.H. Rabinowitz [6]. Since $\mathfrak{L}(\mu_0)$ is Fredholm of index zero, because it is a compact perturbation of the identity, it is apparent from (5.36) that

$$\frac{\mathrm{d}\mathfrak{L}}{\mathrm{d}\mu}(\mu_0)\big(N\big[\mathfrak{L}(\mu_0)\big]\big) \oplus R\big[\mathfrak{L}(\mu_0)\big] = \mathcal{C}_T \times \mathcal{C}_T. \tag{5.38}$$

Thus, μ_0 is a 1-transversal eigenvalue of the analytic family $\mathfrak{L}(\mu)$, $\mu \in \mathbb{R}$, in the sense of [19, Definition 4.2.1]. Hence, the algebraic multiplicity defined there in equals one, i.e.,

$$\chi\big[\mathfrak{L}(\mu); \mu_0\big] = 1,$$

and, therefore, thanks to [19, Theorem 5.3.1], μ_0 is a pole of order one of the resolvent operator $\mathfrak{L}^{-1}(\mu)$, $\mu \neq \mu_0$. Consequently, thanks to [19, Theorem 5.6.2], the crossing number $C(\mu_0)$ defined in (5.3) satisfies

$$C(\mu_0) \in \{-1, 1\}.$$

Therefore, Theorem 5.1 provides us with the following existence result.

THEOREM 5.4. *Fix* $\lambda > 0$ *and consider* μ *as the main bifurcation parameter. Then, Problem* (1.2) *possesses a component of coexistence states*

$$\mathfrak{C}^\lambda_\mu \subset \mathbb{R} \times \operatorname{Int} P \times \operatorname{Int} P$$

such that

$$(\mu_0, \theta_{[\lambda\ell,a]}, 0) \in \bar{\mathfrak{C}}^\lambda_\mu, \tag{5.39}$$

where μ_0 *is defined through* (5.30). *Moreover, if* $\mathfrak{C}^\lambda_\mu$ *is bounded, then there exists* $\mu_* > 0$ *such that*

$$\lambda = \frac{1}{T}\int_0^T b(t)\theta_{[\mu_* m,d]}(t)\,\mathrm{d}t \tag{5.40}$$

and

$$(\mu_*, 0, \theta_{[\mu_* m,d]}) \in \bar{\mathfrak{C}}^\lambda_\mu. \tag{5.41}$$

Therefore, $\mathfrak{C}^\lambda_\mu$ *links the semi-trivial states* $(\mu_0, \theta_{[\lambda\ell,a]}, 0)$ *and* $(\mu_*, 0, \theta_{[\mu_* m,d]})$ *if it is bounded.*

PROOF. The existence of $\mathfrak{C}_\mu^\lambda$ bifurcating from the curve $(\mu, u, v) = (\mu, \theta_{[\lambda\ell, a]}, 0)$ at $\mu = \mu_0$ is an immediate consequence from Theorem 5.1.

Suppose $\mathfrak{C}_\mu^\lambda$ is bounded. Then, it satisfies alternative A2 of Theorem 5.1 and, hence, there exists $(\mu_*, v_*) \in \mathbb{R} \times P$ such that

$$(\mu_*, 0, v_*) \in \bar{\mathfrak{C}}_\mu^\lambda.$$

Thus, there exists a sequence of coexistence states of (1.2), say $\{(\mu_n, u_n, v_n)\}_{n \geqslant 1}$, such that

$$\lim_{n \to \infty} (\mu_n, u_n, v_n) = (\mu_*, 0, v_*).$$

For each $n \geqslant 1$, we have that

$$u_n = \mathfrak{R}_M\big[(\lambda\ell + M)u_n - a u_n^2 - b u_n v_n\big].$$

Thus, setting

$$U_n := \frac{u_n}{\|u_n\|_{\mathcal{C}_T}}, \quad n \geqslant 1,$$

gives

$$U_n = \mathfrak{R}_M\big[(\lambda\ell + M)U_n - a u_n U_n - b v_n U_n\big], \quad n \geqslant 1. \tag{5.42}$$

Since $\{(\lambda\ell + M)U_n - a u_n U_n - b v_n U_n\}_{n \geqslant 1}$ is bounded in $\mathcal{C}_T$ and $\mathfrak{R}_M$ is compact, there exists a subsequence of U_n, labeled again by n, such that

$$\lim_{n \to \infty} U_n = \Phi.$$

Necessarily, $\|\Phi\|_{\mathcal{C}_T} = 1$, and, hence, $\Phi > 0$, since $u_n \gg 0$, $n \geqslant 1$. Moreover, passing to the limit as $n \to \infty$ in (5.42), we find that

$$\Phi = \mathfrak{R}_M\big[(\lambda\ell + M - b v_*)\Phi\big].$$

Thus, $\Phi \in \mathcal{C}_T^1$, $\Phi > 0$, and

$$\Phi' = (\lambda\ell - b v_*)\Phi. \tag{5.43}$$

Suppose $v_* = 0$, then, we find from (5.43) that $\lambda\hat{\ell} = \lambda = 0$, which is impossible, since we are assuming $\lambda > 0$. Thus, $v_* > 0$. Actually, since $(\mu_*, 0, v_*)$ solves (1.2), necessarily

$$\mu_* > 0 \quad \text{and} \quad v_* = \theta_{[\mu_* m, d]} \gg 0.$$

Consequently, (5.43) becomes into

$$\Phi' = (\lambda\ell - b\theta_{[\mu_* m,d]})\Phi, \tag{5.44}$$

and, therefore,

$$\lambda = \frac{1}{T}\int_0^T b(t)\theta_{[\mu_* m,d]}(t)\,\mathrm{d}t,$$

which concludes the proof of the theorem. □

By symmetry, if $\mu > 0$ is fixed and $\lambda \in \mathbb{R}$ is regarded as the main bifurcation parameter, then the following result is satisfied.

THEOREM 5.5. *Fix $\mu > 0$ and consider λ as the main bifurcation parameter. Then, Problem* (1.2) *possesses a component of coexistence states*

$$\mathfrak{C}_\lambda^\mu \subset \mathbb{R} \times \operatorname{Int} P \times \operatorname{Int} P$$

such that

$$(\lambda_0, 0, \theta_{[\mu m,d]}) \in \bar{\mathfrak{C}}_\lambda^\mu, \quad \lambda_0 := \frac{1}{T}\int_0^T b(t)\theta_{[\mu m,d]}(t)\,\mathrm{d}t. \tag{5.45}$$

Moreover, if $\mathfrak{C}_\lambda^\mu$ is bounded, then there exists $\lambda_* > 0$ such that

$$\mu = \frac{1}{T}\int_0^T c(t)\theta_{[\lambda_*\ell,a]}(t)\,\mathrm{d}t \tag{5.46}$$

and

$$(\lambda_*, \theta_{[\lambda_*\ell,a]}, 0) \in \bar{\mathfrak{C}}_\lambda^\mu. \tag{5.47}$$

Therefore, $\mathfrak{C}_\lambda^\mu$ links the semi-trivial states $(\lambda_0, 0, \theta_{[\mu m,d]})$ and $(\lambda_*, \theta_{[\lambda_*\ell,a]}, 0)$ if it is bounded.

5.3. *Local structure of $\mathfrak{C}_\mu^\lambda$ and $\mathfrak{C}_\lambda^\mu$ at $(\mu_0, \theta_{[\lambda\ell,a]}, 0)$ and $(\lambda_0, 0, \theta_{[\mu m,d]})$*

The following result shows that, for each $\lambda > 0$, $\mathfrak{C}_\mu^\lambda$ consists of a real analytic curve of coexistence states of (1.2) in a neighborhood of

$$(\mu, u, v) = (\mu_0, \theta_{[\lambda\ell,a]}, 0).$$

Although this is a consequence from the celebrated theorem of M.G. Crandall and P.H. Rabinowitz [6], we shall give a self-contained proof—whose uniqueness part is based on Theorem 5.2—in order to calculate the bifurcation direction of the curve of coexistence states. Throughout this section, all notation introduced in Section 5.2 will be maintained.

THEOREM 5.6. *Fix* $\lambda > 0$ *and regard to* $\mu \in \mathbb{R}$ *as the main bifurcation parameter. Then, there exist* $\varepsilon > 0$ *and two real analytic maps*

$$\mu : (-\varepsilon, \varepsilon) \to \mathbb{R}, \qquad (u_1, v_1) : (-\varepsilon, \varepsilon) \to R\big[\mathfrak{L}(\mu_0)\big] \times R\big[\mathfrak{L}(\mu_0)\big], \tag{5.48}$$

such that

$$\mu(0) = \mu_0 = \frac{1}{T}\int_0^T c(t)\,\theta_{[\lambda\ell,a]}(t)\,\mathrm{d}t, \quad \big(u_1(0), v_1(0)\big) = (0,0), \tag{5.49}$$

and, for each $s \in (-\varepsilon, \varepsilon)$,

$$\mathfrak{F}\big(\mu(s), \theta_{[\lambda\ell,a]} + s\big[\varphi_u + u_1(s)\big], s\big[\varphi_v + v_1(s)\big]\big) = 0, \tag{5.50}$$

where φ_v *and* φ_u *are the functions defined by* (5.31) *and* (5.33), *respectively. Moreover, there exists* $\delta > 0$ *such that, if* B_δ^0 *stands for the ball of radius* δ *centered at* $(\mu_0, \theta_{[\lambda\ell,a]}, 0) \in \mathbb{R} \times \mathcal{C}_T \times \mathcal{C}_T$ *and, for each* $s \in (-\varepsilon, \varepsilon)$, *we set*

$$\big(u(s), v(s)\big) := \big(\theta_{[\lambda\ell,a]} + s\big[\varphi_u + u_1(s)\big], s\big[\varphi_v + v_1(s)\big]\big), \tag{5.51}$$

then

$$\mathfrak{C}_\mu^\lambda \cap B_\delta^0 = \big\{\big(\mu(s), u(s), v(s)\big) : \ 0 < s < \varepsilon\big\} \cap B_\delta^0. \tag{5.52}$$

Furthermore,

$$\frac{\mathrm{d}\mu}{\mathrm{d}s}(0) = \frac{1}{T}\int_0^T \big[c(t)\varphi_u(t) + d(t)\varphi_v(t)\big]\,\mathrm{d}t. \tag{5.53}$$

PROOF. Consider the operator

$$\mathfrak{G} : \mathbb{R}^2 \times R\big[\mathfrak{L}(\mu_0)\big] \to \mathcal{C}_T \times \mathcal{C}_T$$

defined, for each $(s, \mu, u_1, v_1) \in \mathbb{R}^2 \times R[\mathfrak{L}(\mu_0)]$, by

$$\mathfrak{G}(s, \mu, u_1, v_1) := \begin{cases} s^{-1}\mathfrak{F}\big(\mu, \theta_{[\lambda\ell,a]} + s(\varphi_u + u_1), s(\varphi_v + v_1)\big), & \text{if } s \neq 0, \\ D_{(u,v)}\mathfrak{F}(\mu, \theta_{[\lambda\ell,a]}, 0)(\varphi_u + u_1, \varphi_v + v_1), & \text{if } s = 0. \end{cases}$$

The operator $\mathfrak{G}$ is real analytic and it satisfies

$$\mathfrak{G}(0, \mu_0, 0, 0) = D_{(u,v)}\mathfrak{F}(\mu_0, \theta_{[\lambda\ell,a]}, 0)(\varphi_u, \varphi_v) = \mathfrak{L}(\mu_0)(\varphi_u, \varphi_v) = (0, 0).$$

Moreover, for each $(\mu, u_1, v_1) \in \mathbb{R} \times R[\mathfrak{L}(\mu_0)]$,

$$\begin{aligned}
D_{(\mu,u_1,v_1)}\mathfrak{G}(0,\mu_0,0,0)(\mu,u_1,v_1) &= \lim_{h\to 0}\left[h^{-1}\mathfrak{G}(0,\mu_0+h\mu,hu_1,hv_1)\right]\\
&= \lim_{h\to 0}\left[h^{-1}D_{(u,v)}\mathfrak{F}(\mu_0+h\mu,\theta_{[\lambda\ell,a]},0)(\varphi_u+hu_1,\varphi_v+hv_1)\right]\\
&= \lim_{h\to 0}\left[h^{-1}\mathfrak{L}(\mu_0+h\mu)(\varphi_u+hu_1,\varphi_v+hv_1)\right]\\
&= \mathfrak{L}(\mu_0)(u_1,v_1)+\mu\frac{\mathrm{d}\mathfrak{L}}{\mathrm{d}\mu}(\mu_0)(\varphi_u,\varphi_v).
\end{aligned}$$

Thanks to the proof of Theorem 5.1, we already know that

$$N\big[\mathfrak{L}(\mu_0)\big] \oplus R\big[\mathfrak{L}(\mu_0)\big] = \mathcal{C}_T \times \mathcal{C}_T,$$

though this easily follows from the fact that $(\varphi_u, \varphi_v) \notin R[\mathfrak{L}(\mu_0)]$. Therefore,

$$\mathfrak{L}(\mu_0)|_{R[\mathfrak{L}(\mu_0)]} : R\big[\mathfrak{L}(\mu_0)\big] \to R\big[\mathfrak{L}(\mu_0)\big]$$

is a linear isomorphism and, hence, it follows from (5.36) that

$$D_{(\mu,u_1,v_1)}\mathfrak{G}(0,\mu_0,0,0) : \mathbb{R} \times R\big[\mathfrak{L}(\mu_0)\big] \to \mathcal{C}_T \times \mathcal{C}_T$$

is a linear isomorphism as well. Consequently, thanks to the implicit function theorem, there exist $\varepsilon > 0$ and the real analytic maps (5.48), satisfying (5.49), such that, for each $s \in (-\varepsilon, \varepsilon)$,

$$\mathfrak{G}\big(s, \mu(s), u_1(s), v_1(s)\big) = 0.$$

Moreover, if

$$\mathfrak{G}(s, \mu, u_1, v_1) = 0$$

for some (s, μ, u_1, v_1) sufficiently close to $(0, \mu_0, 0, 0)$, then

$$(s, \mu, u_1, v_1) = \big(s, \mu(s), u_1(s), v_1(s)\big).$$

It should be noted that, by the definition of $\mathfrak{G}$ itself, for each $s \in (-\varepsilon, \varepsilon)$, (5.50) is satisfied. Now, we will prove the uniqueness result.

Thanks to Theorem 5.2, there exists $\delta > 0$ such that, for each

$$(\mu, u, v) \in \big[\mathfrak{C}^\lambda_\mu \setminus \big\{(\mu_0, \theta_{[\lambda\ell,a]}, 0)\big\}\big] \cap B_\delta,$$

there exists a unique $(s, \tilde{u}, \tilde{v}) \in \mathbb{R} \times R[\mathfrak{L}(\mu_0)]$ such that

$$\mu = \mu(s), \quad (u, v) = (\theta_{[\lambda\ell,a]}, 0) + s(\varphi_u, \varphi_v) + \big(\tilde{u}, \tilde{v}\big), \tag{5.54}$$

with $s > \eta\,\|(u-\theta_{[\lambda\ell,a]}, v)\| > 0$. Moreover,

$$\mu = \mu_0 + \mathrm{o}(1) \quad \text{and} \quad \big(\tilde{u}, \tilde{v}\big) = \mathrm{o}(s) \quad \text{as } s \to 0. \tag{5.55}$$

So, setting

$$U(s) := s^{-1}\tilde{u}(s) = \mathrm{o}(1), \qquad V(s) := s^{-1}\tilde{v}(s) = \mathrm{o}(1),$$

we have that $(U(s), V(s)) \in R[\mathfrak{L}(\mu_0)]$ and

$$\mathfrak{F}\big(\mu(s), \theta_{[\lambda\ell,a]} + s\big(\varphi_u + U(s)\big), s\big(\varphi_s + V(s)\big)\big) = 0.$$

Thus,

$$\mathfrak{G}\big(s, \mu(s), U(s), V(s)\big) = 0$$

and, therefore, by the uniqueness obtained as an application of the implicit function theorem to $\mathfrak{G}$, if δ is taken sufficiently small, we have that

$$\big(U(s), V(s)\big) = \big(u_1(s), v_1(s)\big)$$

and, consequently,

$$(\mu, u, v) = \big(\mu(s), u(s), v(s)\big),$$

which concludes the proof of (5.52).

To prove (5.53), consider the second equation of (5.50). Then, after division by s, gives

$$\begin{aligned}
&\varphi_v + s\frac{\mathrm{d}v_1}{\mathrm{d}s}(0) + \mathrm{O}\big(s^2\big) \\
&\quad = \mathfrak{R}_M\bigg\{\bigg[\bigg(\mu_0 + s\frac{\mathrm{d}\mu}{\mathrm{d}s}(0) + \mathrm{O}\big(s^2\big)\bigg)m + M\bigg]\bigg(\varphi_v + s\frac{\mathrm{d}v_1}{\mathrm{d}s}(0) + \mathrm{O}\big(s^2\big)\bigg) \\
&\qquad - \mathrm{d}s\bigg(\varphi_v + s\frac{\mathrm{d}v_1}{\mathrm{d}s}(0) + \mathrm{O}\big(s^2\big)\bigg)^2 - c\big(\theta_{[\lambda\ell,a]} + s\varphi_u + \mathrm{O}\big(s^2\big)\big) \\
&\qquad \times \bigg(\varphi_v + s\frac{\mathrm{d}v_1}{\mathrm{d}s}(0) + \mathrm{O}\big(s^2\big)\bigg)\bigg\}.
\end{aligned}$$

By definition,

$$\varphi_v = \mathfrak{R}_M\big\{(\mu_0 m + M - c\theta_{[\lambda\ell,a]})\varphi_v\big\}.$$

Thus, dividing by s the previous identity, passing to the limit as $s \to 0$, and rearranging terms yields to

$$\frac{\mathrm{d}v_1}{\mathrm{d}s}(0) = \mathfrak{R}_M\bigg[(\mu_0 m + M - c\theta_{[\lambda\ell,a]})\frac{\mathrm{d}v_1}{\mathrm{d}s}(0) + \frac{\mathrm{d}\mu}{\mathrm{d}s}(0)m\varphi_v - d\varphi_v^2 - c\varphi_u\varphi_v\bigg],$$

or, equivalently,

$$\frac{\mathrm{d}}{\mathrm{d}t}\frac{\mathrm{d}v_1}{\mathrm{d}s}(0) = (\mu_0 m - c\theta_{[\lambda\ell,a]})\frac{\mathrm{d}v_1}{\mathrm{d}s}(0) + \frac{\mathrm{d}\mu}{\mathrm{d}s}(0)m\varphi_v - d\varphi_v^2 - c\varphi_u\varphi_v.$$

Thus, thanks to Proposition 2.1(d),

$$\int_0^T \mathrm{e}^{-\int_0^t(\mu_0 m - c\theta_{[\lambda\ell,a]})}\left(\frac{\mathrm{d}\mu}{\mathrm{d}s}(0)m(t)\varphi_v(t) - d(t)\varphi_v^2(t) - c(t)\varphi_u(t)\varphi_v(t)\right)\mathrm{d}t = 0,$$

and, hence, (5.31) entails

$$\int_0^T \left(\frac{\mathrm{d}\mu}{\mathrm{d}s}(0)m(t) - d(t)\varphi_v(t) - c(t)\varphi_u(t)\right)\mathrm{d}t = 0.$$

Therefore,

$$\frac{\mathrm{d}\mu}{\mathrm{d}s}(0) = \frac{1}{T}\int_0^T \big[c(t)\varphi_u(t) + d(t)\varphi_v(t)\big]\,\mathrm{d}t,$$

since $\hat{m} = 1$. This concludes the proof. □

By symmetry, for each $\mu > 0$, $\mathfrak{C}_\lambda^\mu$ consists of a real analytic curve of coexistence states of (1.2) in a neighborhood of $(\lambda, u, v) = (\lambda_0, 0, \theta_{[\mu m,d]})$. Actually, setting

$$\lambda_0 := \frac{1}{T}\int_0^T b(t)\theta_{[\mu m,d]}(t)\,\mathrm{d}t, \qquad \tilde{\varphi}_u(t) := \mathrm{e}^{\int_0^t(\lambda_0\ell - b\theta_{[\mu m,d]})}, \quad t \in \mathbb{R}, \tag{5.56}$$

and

$$\tilde{\varphi}_v := -\mathfrak{R}_{2d\theta_{[\mu m,d]}-\mu m}(c\theta_{[\mu m,d]}\tilde{\varphi}_u), \tag{5.57}$$

there exists $\delta > 0$ such that in the ball of radius $\delta > 0$ centered at $(\lambda_0, 0, \theta_{[\mu m,d]})$ the component $\mathfrak{C}_\lambda^\mu$ consists of a real analytic curve of the form

$$(\lambda, u, v) = \big(\lambda(s), s\big(\tilde{\varphi}_u + \mathrm{O}(s)\big), \theta_{[\mu m,d]} + s\big(\tilde{\varphi}_v + \mathrm{O}(s)\big)\big), \quad s \sim 0,\ s > 0,$$

where $\lambda(0) = \lambda_0$ and

$$\frac{\mathrm{d}\lambda}{\mathrm{d}s}(0) = \frac{1}{T}\int_0^T \big[b(t)\tilde{\varphi}_v(t) + a(t)\tilde{\varphi}_u(t)\big]\,\mathrm{d}t. \tag{5.58}$$

6. The symbiotic model ($b < 0$ and $c < 0$)

In this section we analyze the structure of the set of coexistence states of (1.2) in the special case when $b < 0$ and $c < 0$. Our main result shows that, for each $\lambda > 0$ and $\mu > 0$, the components of coexistence states of (1.2) constructed in Section 5, $\mathfrak{C}_\lambda^\mu$ and $\mathfrak{C}_\mu^\lambda$, are real analytic curves. These curves fiber a real analytic surface entirely formed by coexistence states and linking the corresponding surfaces of semi-trivial solutions along their curves of neutral stability. Also, the stability of the coexistence states along these curves is completely ascertained. It turns out that the stability of the coexistence states along these curves changes at any turning point along the curve, while it remains unchanged when an hysteresis point is passed by. Some of the results of this section are substantial improvements of some results of M.A. Krasnosel'skii [16]. The theory developed in this section can be viewed as a development of many ideas and results going back to [17].

6.1. *Periodic systems of cooperative type*

In this section we study the linear periodic system

$$\begin{cases} u' = \alpha u + \beta v, \\ v' = \gamma u + \rho v, \end{cases} \tag{6.1}$$

where $\alpha, \beta, \gamma, \rho \in \mathcal{C}_T$ satisfy

$$\int_0^T \alpha < 0, \qquad \int_0^T \rho < 0, \qquad \beta > 0, \qquad \gamma > 0, \tag{6.2}$$

as well as its associated Cauchy problem

$$\begin{cases} u' = \alpha u + \beta v, \\ v' = \gamma u + \rho v, \\ u(0) = u_0, \quad v(0) = v_0. \end{cases} \tag{6.3}$$

The next result is the key theorem from which most of the results of this section will follow.

THEOREM 6.1. *Suppose* (6.1) *possesses a solution* $(u, v) \in \mathcal{C}_T^1 \times \mathcal{C}_T^1 \setminus \{(0,0)\}$. *Then, either* $u \gg 0$ *and* $v \gg 0$, *or else* $u \ll 0$ *and* $v \ll 0$. *Therefore, all the coexistence states of* (1.2) *must be ordered, in the sense that, for any pair of coexistence states,* $(u_1, v_1) \neq (u_2, v_2)$, *either* $u_1 \gg u_2$ *and* $v_1 \gg v_2$, *or* $u_1 \ll u_2$ *and* $v_1 \ll v_2$.

PROOF. If $u = 0$, then $v' = \rho v$, and it follows from Proposition 2.1 that $v = 0$. Thus, $u \neq 0$, since $(u, v) \neq (0, 0)$. As the system is linear, without lost of generality we can assume that $u(t) > 0$ for some $t \in \mathbb{R}$. If $u \gg 0$, then $\gamma u > 0$ and, therefore,

$$v = \mathfrak{R}_{-\rho}(\gamma u) \gg 0,$$

which concludes the proof of the first thesis of the theorem. To show that $u \gg 0$ we will argue by contradiction. Suppose there are $t_0 < t_1$ such that

$$u(t_0) = u(t_1) = 0 \quad \text{and} \quad u(t) > 0 \quad \text{for each } t \in (t_0, t_1). \tag{6.4}$$

Then, for each $t \in \mathbb{R}$, we have that

$$u(t) = \int_{t_0}^{t} \mathrm{e}^{\int_\tau^t \alpha} \beta(\tau) v(\tau)\, \mathrm{d}\tau \tag{6.5}$$

and

$$v(t) = \mathrm{e}^{\int_{t_0}^t \rho} v(t_0) + \int_{t_0}^{t} \mathrm{e}^{\int_\tau^t \rho} \gamma(\tau) u(\tau)\, \mathrm{d}\tau. \tag{6.6}$$

Suppose $v(t_0) \geqslant 0$. Then, thanks to (6.4) and (6.6), we find that, for each $t \in [t_0, t_1]$,

$$v(t) \geqslant \mathrm{e}^{\int_{t_0}^t \rho} v(t_0) \geqslant 0,$$

since $\gamma u \geqslant 0$. Thus, (6.4) and (6.5) imply

$$\begin{aligned} 0 = u(t_1) &= \int_{t_0}^{t_1} \mathrm{e}^{\int_\tau^{t_1} \alpha} \beta(\tau) v(\tau)\, \mathrm{d}\tau \\ &\geqslant \int_{t_0}^{\frac{t_0+t_1}{2}} \mathrm{e}^{\int_\tau^{t_1} \alpha} \beta(\tau) v(\tau)\, \mathrm{d}\tau \\ &= \exp\biggl(\int_{\frac{t_0+t_1}{2}}^{t_1} \alpha\biggr) \int_{t_0}^{\frac{t_0+t_1}{2}} \exp\biggl(\int_\tau^{\frac{t_0+t_1}{2}} \alpha\biggr) \beta(\tau) v(\tau)\, \mathrm{d}\tau \\ &= \exp\biggl(\int_{\frac{t_0+t_1}{2}}^{t_1} \alpha\biggr) u\biggl(\frac{t_0+t_1}{2}\biggr) > 0, \end{aligned}$$

which is impossible. Hence, $v(t_0) < 0$. So, there is $\delta > 0$ such that $t_0 < t_0 + \delta < t_1$, for which $v(t) < 0$ if $t \in [t_0, t_0 + \delta]$. Thus, we find from (6.5) that $u(t) \leqslant 0$ for each $t \in [t_0, t_0 + \delta]$, which contradicts (6.4). Therefore, necessarily $u \gg 0$, which concludes the proof of the first statement.

Now, suppose $(u_1, v_1) \neq (u_2, v_2)$ are two coexistence states of (1.2). Then,

$$\begin{aligned} (u_2 - u_1)' &= \lambda \ell (u_2 - u_1) - a(u_2 + u_1)(u_2 - u_1) - b u_2 v_2 + b u_1 v_1 \\ &= \bigl[\lambda \ell - a(u_2 + u_1) - b v_2\bigr](u_2 - u_1) - b u_1 (v_2 - v_1). \end{aligned}$$

By symmetry,

$$(v_2 - v_1)' = \bigl[\mu m - d(v_2 + v_1) - c u_2\bigr](v_2 - v_1) - c v_1 (u_2 - u_1).$$

Thus, the pair

$$(U,V):=(u_2-u_1,v_2-v_1)\in\mathcal{C}^1_T\times\mathcal{C}^1_T$$

satisfies

$$\begin{cases} U'=\bigl[\lambda\ell-a(u_2+u_1)-bv_2\bigr]U-bu_1V,\\ V'=\bigl[\mu m-d(v_2+v_1)-cu_2\bigr]V-cv_1U. \end{cases}$$

Since $u_1\gg 0$, $v_1\gg 0$, $b<0$ and $c<0$, necessarily $-bu_1>0$ and $-cv_1>0$. Moreover, since $u_2\gg 0$ and $v_2\gg 0$ satisfy

$$\frac{u_2'}{u_2}=\lambda\ell-au_2-bv_2,\qquad \frac{v_2'}{v_2}=\mu m-dv_2-cu_2,$$

integrating in $[0,T]$ gives

$$\int_0^T(\lambda\ell-au_2-bv_2)=0,\qquad \int_0^T(\mu m-dv_2-cu_2)=0. \tag{6.7}$$

Thus,

$$\int_0^T\bigl[\lambda\ell-a(u_2+u_1)-bv_2\bigr]=-\int_0^T a(t)u_1(t)\,\mathrm{d}t<0$$

and

$$\int_0^T\bigl[\mu m-d(v_2+v_1)-cu_2\bigr]=-\int_0^T d(t)v_1(t)\,\mathrm{d}t<0.$$

Therefore, by the first part of the theorem, either $U\gg 0$ and $V\gg 0$, or $U\ll 0$ and $V\ll 0$, which concludes the proof. □

PROPOSITION 6.2. *Suppose* $(\bar u,\bar v)\in\mathcal{C}^1(\mathbb{R}_+)\times\mathcal{C}^1(\mathbb{R}_+)$, $\mathbb{R}_+:=[0,\infty)$, *satisfy*

$$\begin{cases} \bar u'\geqslant\alpha\bar u+\beta\bar v,\\ \bar v'\geqslant\gamma\bar u+\rho\bar v,\\ \bar u(0)>0,\quad \bar v(0)>0. \end{cases} \tag{6.8}$$

Then, $\bar u(t)>0$ *and* $\bar v(t)>0$ *for each* $t\geqslant 0$.

If $u_0+v_0>0$ *and* $u_0v_0=0$, *then there exists* $t_0>0$ *such that the solution* (u,v) *of* (6.3) *satisfies* $u(t)>0$ *and* $v(t)>0$ *for each* $t\geqslant t_0$.

PROOF. Setting

$$d:=\bar u'-\alpha\bar u-\beta\bar v\geqslant 0,\qquad \delta:=\bar v'-\gamma\bar u-\rho\bar v\geqslant 0,$$

and integrating the resulting system show that, for each $t \in \mathbb{R}_+$,

$$\bar{u}(t) = \mathrm{e}^{\int_0^t \alpha} \bar{u}(0) + \int_0^t \mathrm{e}^{\int_\tau^t \alpha} \bigl[\beta(\tau)\bar{v}(\tau) + d(\tau)\bigr] \, \mathrm{d}\tau \tag{6.9}$$

and

$$\bar{v}(t) = \mathrm{e}^{\int_0^t \rho} \bar{v}(0) + \int_0^t \mathrm{e}^{\int_\tau^t \rho} \bigl[\gamma(\tau)\bar{u}(\tau) + \delta(\tau)\bigr] \, \mathrm{d}\tau. \tag{6.10}$$

Now, suppose $\bar{u}(0) > 0$ and $\bar{v}(0) > 0$. Then, either $\bar{u}(t) > 0$ for each $t \in \mathbb{R}_+$, or there exists t^* such that

$$\bar{u}\bigl(t^*\bigr) = 0 \quad \text{and} \quad \bar{u}(t) > 0 \quad \text{for each } t \in \bigl[0, t^*\bigr). \tag{6.11}$$

Suppose (6.11) occurs. Then, since $\bar{u}(0) > 0$, $\bar{v}(0) > 0$, $\beta > 0$ and $d \geqslant 0$, it follows from (6.9) that there exists $\tilde{t} \in (0, t^*)$ such that

$$\bar{v}\bigl(\tilde{t}\bigr) = 0 \quad \text{and} \quad \bar{v}(t) > 0 \quad \text{for each } t \in \bigl[0, \tilde{t}\bigr),$$

which contradicts (6.10), since $\bar{v}(0) > 0$ and $\gamma \geqslant 0$, $\delta \geqslant 0$ and $\bar{u} \geqslant 0$ in $[0, \tilde{t}]$. Therefore, $\bar{u}(t) > 0$ for each $t \in \mathbb{R}_+$ and, thanks to (6.10), $\bar{v}(t) > 0$ for each $t \in \mathbb{R}_+$. This concludes the proof of the first part of the proposition.

Now, suppose $u_0 > 0$ and $v_0 = 0$, and let (u, v) denote the unique solution of (6.3). Thanks to the first part of the proposition, for each $\varepsilon > 0$ the solution $(u_\varepsilon, v_\varepsilon)$ of (6.1) with initial data $(u_\varepsilon(0), v_\varepsilon(0)) = (u_0, v_0 + \varepsilon)$ satisfies $u_\varepsilon(t) > 0$ and $v_\varepsilon(t) > 0$ for each $t \geqslant 0$. Thus, by continuous dependence with respect to the initial data, passing to the limit as $\varepsilon \downarrow 0$ we find that $u > 0$ and $v \geqslant 0$. Hence, for each $t \geqslant 0$,

$$u(t) = \mathrm{e}^{\int_0^t \alpha} u_0 + \int_0^t \mathrm{e}^{\int_\tau^t \alpha} \beta(\tau) v(\tau) \, \mathrm{d}\tau \geqslant \mathrm{e}^{\int_0^t \alpha} u_0 > 0.$$

If $v = 0$ in $\mathbb{R}_+$, then we find from the v-equation that $\gamma u = 0$ in $\mathbb{R}_+$, which is impossible since $\gamma > 0$ and $u \gg 0$. Thus, there exists $t_0 > 0$ such that $v(t_0) > 0$. Therefore, since $u(t_0) > 0$, by applying the first part of this theorem, we find that $u(t) > 0$ and $v(t) > 0$ for each $t \geqslant t_0$, which concludes the proof. □

Subsequently, we denote by $U(t)$ the fundamental matrix of solutions of (6.1) such that $U(0) = I := I_{\mathbb{R}^2}$. Then, $U(T)$ provides us with the Poincaré map associated to (6.1). Thanks to Liouville's formula,

$$0 < \det U(T) = \mathrm{e}^{\int_0^T (\alpha + \rho)} < 1,$$

since $\int_0^T (\alpha + \rho) < 0$. Thus, if we denote by ν_1 and ν_2 the two eigenvalues of $U(T)$, counting algebraic multiplicities, then

$$0 < \nu_1 \nu_2 < 1. \tag{6.12}$$

Actually, the following result is satisfied.

THEOREM 6.3. *The characteristic multipliers of* (6.1), ν_1 *and* ν_2, *are real and distinct, and satisfy* (6.12). *Moreover, if we order them so that* $0 < \nu_1 < \nu_2$, *then,* $0 < \nu_1 < 1$,

$$N\big[U(T) - \nu_1 I\big] = \operatorname{span}\big[(x_0, y_0)\big] \quad \textit{with } x_0 < 0 \textit{ and } y_0 > 0,$$

and

$$N\big[U(T) - \nu_2 I\big] = \operatorname{span}\big[(x_0, y_0)\big] \quad \textit{with } x_0 > 0 \textit{ and } y_0 > 0.$$

In particular, (6.1) *is asymptotically stable if* $\nu_2 < 1$, *neutrally stable if* $\nu_2 = 1$, *and unstable if* $\nu_2 > 1$. *Furthermore,*

$$\lambda_0 := -\frac{1}{T}\operatorname{Log}\nu_2 \tag{6.13}$$

provides us with the unique value of $\lambda \in \mathbb{R}$ *for which the eigenvalue problem*

$$\begin{cases} u' = \alpha u + \beta v + \lambda u, \\ v' = \gamma u + \rho v + \lambda v, \end{cases} \tag{6.14}$$

admits a solution $(u, v) \in \mathcal{C}^1_T \times \mathcal{C}^1_T$ *with* $u \gg 0$ *and* $v \gg 0$.

PROOF. Suppose $u_0 > 0$, $v_0 > 0$, and let $(u(t), v(t))$ denote the unique solution of (6.3). Then, thanks to Proposition 6.2, $u(T) > 0$ and $v(T) > 0$, and, hence, $U(T)$ sends the interior of the first quadrant of the plane into itself. Setting

$$U(T) = \begin{pmatrix} u_{11} & u_{12} \\ u_{21} & u_{22} \end{pmatrix},$$

the invariance of the first quadrant entails $u_{ij} \geqslant 0$ for each $i, j \in \{1, 2\}$. On the other hand, the eigenvalues of $U(T)$ (ν_1 and ν_2) are the roots of

$$z^2 - (u_{11} + u_{22})z + u_{11}u_{22} - u_{12}u_{21} = 0,$$

which are given through

$$\frac{1}{2}\big(u_{11} + u_{22} \pm \sqrt{\Delta}\big),$$

where

$$\Delta := (u_{11} + u_{22})^2 - 4(u_{11}u_{22} - u_{12}u_{21}) = (u_{11} - u_{22})^2 + 4u_{12}u_{21} \geqslant 0.$$

Thus, both are real. Moreover, since

$$\det U(T) = u_{11}u_{22} - u_{12}u_{21} = \nu_1\nu_2 > 0,$$

necessarily

$$u_{11} > 0, \quad u_{22} > 0, \quad \nu_1 + \nu_2 = u_{11} + u_{22}.$$

We now show that $u_{12} > 0$ and $u_{21} > 0$. Indeed, if $u_{12} = 0$, then

$$\{\nu_1, \nu_2\} = \{u_{11}, u_{22}\}$$

and, hence,

$$N\big[U(T) - u_{22}I\big] = \operatorname{span}\big[(0, 1)\big].$$

Consequently, the solution of (6.3) with initial data $(0, 1)$, say (u, v), satisfies $u(nT) = 0$ for each $n \geqslant 1$, which contradicts the second part of Proposition 6.2. This contradiction shows that $u_{12} > 0$. Similarly, $u_{21} > 0$ follows. Thus, $\Delta > 0$ and, therefore, $\nu_1 \neq \nu_2$, say $0 < \nu_1 < \nu_2$. Now, note that

$$\min\{u_{11}, u_{22}\} < \nu_2 = \frac{1}{2}\big(u_{11} + u_{22} + \sqrt{\Delta}\,\big).$$

In case $u_{11} = \min\{u_{11}, u_{22}\}$, $(u_{12}/(\nu_2 - u_{11}), 1)$ provides us with an eigenvector of $U(T)$ associated to ν_2, while, in case $u_{22} = \min\{u_{11}, u_{22}\}$, $(1, u_{21}/(\nu_2 - u_{22}))$ provides us with an eigenvector of $U(T)$ associated to ν_2. In both situations the two components of the eigenvector are positive. Similarly, in case $u_{11} = \min\{u_{11}, u_{22}\}$, $(1, u_{21}/(\nu_1 - u_{22}))$ is an eigenvector of $U(T)$ associated to ν_1 whose second component is negative, since

$$\nu_1 = u_{11} + u_{22} - \nu_2 < u_{22}.$$

By symmetry, in case $u_{22} = \min\{u_{11}, u_{22}\}$, $(u_{12}/(\nu_1 - u_{11}), 1)$ is an eigenvector of $U(T)$ associated to ν_1 whose second component is negative. Therefore, the eigenvector of $U(T)$ associated to ν_2 can be chosen in the interior of the first quadrant, while the eigenvector associated to ν_1 can be chosen in the interior of the second quadrant.

Now, note that the change of variable

$$(u, v) = \mathrm{e}^{\lambda t}(x, y)$$

transforms (6.14) into

$$\begin{cases} x' = \alpha x + \beta y, \\ y' = \gamma x + \rho y. \end{cases}$$

Thus, for any $(u_0, v_0) \in \mathbb{R}^2$, the unique solution of (6.14) satisfying

$$\big(u(0), v(0)\big) = (u_0, v_0)$$

is given through

$$\big(u(t), v(t)\big) = \mathrm{e}^{\lambda t} U(t)(u_0, v_0).$$

Therefore, the Poincaré map of (6.14) is given by

$$P_T := \mathrm{e}^{\lambda T} U(T)$$

and, consequently, the multipliers of (6.14) are $\mathrm{e}^{\lambda T}\nu_j$, $j \in \{1, 2\}$. Thus, the eigenvalue problem (6.14) possesses a T-periodic solution if, and only, if

$$\lambda \in \left\{ -\frac{1}{T}\operatorname{Log}\nu_1, -\frac{1}{T}\operatorname{Log}\nu_2 \right\}.$$

By the analysis already done, the unique value of λ providing us with a T-periodic solution having both components positive is the one given by (6.13), as the other eigenvalue provides us with a T-periodic solution whose components have contrary sign. This concludes the proof. □

Subsequently, the value λ_0 defined by (6.13) will be called the *principal eigenvalue* of (6.14). It should be noted that (6.1) is asymptotically stable if, and only if $\lambda_0 > 0$, whereas it is unstable if, and only if, $\lambda_0 < 0$. The following result provides us with an extremely useful criterion for ascertaining the stability of (6.1).

THEOREM 6.4. *The following properties are satisfied*:

(a) *System* (6.1) *is stable* ($\nu_2 < 1$) *if, and only if, there exists* $(\bar{u}, \bar{v}) \in \mathcal{C}^1_T \times \mathcal{C}^1_T$ *with* $\bar{u} \gg 0$ *and* $\bar{v} \gg 0$ *such that*

$$\begin{cases} \bar{u}' \geqslant \alpha\bar{u} + \beta\bar{v}, \\ \bar{v}' \geqslant \gamma\bar{u} + \rho\bar{v}, \end{cases} \tag{6.15}$$

with some of these inequalities strict.

(b) *System* (6.1) *is unstable* ($\nu_2 > 1$) *if, and only if, there exits* $(\underline{u}, \underline{v}) \in \mathcal{C}^1_T \times \mathcal{C}^1_T$ *with* $\underline{u} \gg 0$ *and* $\underline{v} \gg 0$ *such that*

$$\begin{cases} \underline{u}' \leqslant \alpha\underline{u} + \beta\underline{v}, \\ \underline{v}' \leqslant \gamma\underline{u} + \rho\underline{v}, \end{cases} \tag{6.16}$$

with some of these inequalities strict.

PROOF. First we will prove part (a). If $\nu_2 < 1$, then the principal eigenvalue of (6.14) is positive. Indeed,

$$\lambda_0 = -\frac{1}{T}\operatorname{Log}\nu_2 > 0$$

and, hence, any T-periodic strongly positive solution associated to λ_0 provides us with a strict supersolution of (6.1). This shows the necessity of the existence of the supersolution. To show the sufficiency of this condition, suppose there exists $(\bar{u}, \bar{v}) \in \mathcal{C}^1_T \times \mathcal{C}^1_T$ with $\bar{u} \gg 0$ and $\bar{v} \gg 0$ satisfying (6.15) with some of the inequalities strict. Now, pick

$$(u_0, v_0) \in N\big[U(T) - \nu_2 I\big]$$

with $u_0 > 0$ and $v_0 > 0$, and let $(u(t), v(t))$ denote the unique solution of (6.3). Then,

$$\big(u(nT), v(nT)\big) = \nu_2^n (u_0, v_0), \quad n \geqslant 0.$$

Now, pick $R > 0$ satisfying

$$0 < u_0 < R\bar{u}(0), \qquad 0 < v_0 < R\bar{v}(0),$$

and consider the auxiliary function

$$x := R\bar{u} - u, \qquad y := R\bar{v} - v.$$

Then, by construction,

$$\begin{cases} x' \geqslant \alpha x + \beta y, \\ y' \geqslant \gamma x + \rho y, \\ x(0) > 0, \quad y(0) > 0, \end{cases} \tag{6.17}$$

and, hence, thanks to Proposition 6.2,

$$x(t) > 0 \quad \text{and} \quad y(t) > 0 \quad \text{for each } t \in \mathbb{R}_+.$$

Equivalently,

$$0 < u(t) < R\bar{u}(t) \quad \text{and} \quad 0 < v(t) < R\bar{v}(t) \quad \text{for each } t \in \mathbb{R}_+,$$

since $u_0 > 0$ and $v_0 > 0$. In particular, the sequence

$$\big(u(nT), v(nT)\big) = \nu_2^n (u_0, v_0), \quad n \geqslant 0,$$

is bounded above and, therefore, $\nu_2 \leqslant 1$. Suppose $\nu_2 = 1$. Then, $\lambda_0 = 0$ and, thanks to Theorem 6.3, (6.1) possesses a T-solution (p, q) with $p \gg 0$ and $q \gg 0$. On the other hand, setting

$$d := \bar{u}' - \alpha\bar{u} - \beta\bar{v}, \qquad \delta := \bar{v}' - \gamma\bar{u} - \rho\bar{v},$$

we have that $d \geqslant 0$, $\delta \geqslant 0$, $d + \delta > 0$, and

$$\begin{cases} \bar{u}' = \alpha\bar{u} + \beta\bar{v} + d, \\ \bar{v}' = \gamma\bar{u} + \rho\bar{v} + \delta. \end{cases}$$

Consequently, for each $\xi \in \mathbb{R}$, the pair

$$(u_\xi, v_\xi) := (\bar{u} - \xi p, \bar{v} - \xi q)$$

provides us with a T-periodic solution of

$$\begin{cases} u' = \alpha u + \beta v + d, \\ v' = \gamma u + \rho v + \delta. \end{cases} \tag{6.18}$$

Since $\bar{u} \gg 0$ and $\bar{v} \gg 0$, we have that $u_\xi \gg 0$ and $v_\xi \gg 0$ for sufficiently small $\xi > 0$. Moreover, since $p \gg 0$ and $q \gg 0$, we have that $u_\xi \ll 0$ and $v_\xi \ll 0$ for sufficiently large $\xi > 0$. Thus, there exists $\xi > 0$ such that $u_\xi \geqslant 0$, $v_\xi \geqslant 0$ and, for some $t_0 \in \mathbb{R}$, either $u_\xi(t_0) = 0$, or $v_\xi(t_0) = 0$. Without lost of generality we can assume that $u_\xi(t_0) = 0$. Then, for each $t \geqslant t_0$, we have that

$$u_\xi(t) = \int_{t_0}^{t} \mathrm{e}^{\int_\tau^t \alpha} \big[\beta v_\xi(\tau) + d(\tau)\big] \, \mathrm{d}\tau. \tag{6.19}$$

If $\beta v_\xi + d > 0$, then, we find from (6.19) that $u_\xi(t_0 + nT) > 0$ for each $n \geqslant 2$, which contradicts the periodicity of u_ξ, since $u_\xi(t_0) = 0$. Thus,

$$\beta v_\xi = d = 0, \tag{6.20}$$

and, thanks again to (6.19),

$$u_\xi = 0.$$

Thus, substituting into the v-equation of (6.18) shows that

$$v'_\xi = \rho v_\xi + \delta.$$

Necessarily,

$$v_\xi = \mathfrak{R}_{-\rho}(\delta) \gg 0,$$

since $\delta > 0$, and, therefore, $\beta v_\xi > 0$, which contradicts (6.20) and shows $\nu_2 < 1$. This concludes the proof of part (a).

Now, we will prove part (b). Suppose $\nu_2 > 1$. Then,

$$\lambda_0 = -\frac{1}{T} \operatorname{Log} \nu_2 < 0$$

and, hence, any T-periodic strongly positive solution of (6.14) associated to λ_0 provides us with a strict subsolution of (6.1). To show the converse, let $(\underline{u}, \underline{v}) \in \mathcal{C}_T^1 \times \mathcal{C}_T^1$ with $\underline{u} \gg 0$ and $\underline{v} \gg 0$ satisfying (6.16) with some of the inequalities strict. Pick

$$(u_0, v_0) \in N\big[U(T) - \nu_2 I\big]$$

with $u_0 > 0$ and $v_0 > 0$, and let $(u(t), v(t))$ denote the unique solution of (6.3). Then,

$$\big(u(nT), v(nT)\big) = \nu_2^n(u_0, v_0), \quad n \geqslant 0. \tag{6.21}$$

Now, for each $\varepsilon > 0$ we consider the auxiliary function

$$(U_\varepsilon, V_\varepsilon) := (u - \varepsilon \underline{u}, v - \varepsilon \underline{v}).$$

For any $\varepsilon > 0$, $(U_\varepsilon, V_\varepsilon)$ is a strict supersolution of (6.1). Moreover, for sufficiently small $\varepsilon > 0$ we have that

$$U_\varepsilon(0) = u_0 - \varepsilon \underline{u}(0) > 0 \quad \text{and} \quad V_\varepsilon(0) = v_0 - \varepsilon \underline{v}(0) > 0.$$

Choose one of these ε's. Then, thanks to Proposition 6.2, $U_\varepsilon(t) > 0$ and $V_\varepsilon(t) > 0$ for each $t \geqslant 0$. In particular, for each $n \geqslant 0$,

$$\varepsilon \underline{u}(0) = \varepsilon \underline{u}(nT) < u(nT) = \nu_2^n u_0$$

and, therefore, $\nu_2 \geqslant 1$.

Suppose $\nu_2 = 1$. Then, $\lambda_0 = 0$ and, thanks to Theorem 6.3, (6.1) possesses a T-solution (p, q) with $p \gg 0$ and $q \gg 0$. On the other hand, setting

$$d := \underline{u}' - \alpha \underline{u} - \beta \underline{v}, \qquad \delta := \underline{v}' - \gamma \underline{u} - \rho \underline{v},$$

we have that $d \leqslant 0$, $\delta \leqslant 0$, $d + \delta < 0$, and

$$\begin{cases} \underline{u}' = \alpha \underline{u} + \beta \underline{v} + d, \\ \underline{v}' = \gamma \underline{u} + \rho \underline{v} + \delta. \end{cases}$$

Consequently, for each $\xi \in \mathbb{R}$, the pair

$$(u_\xi, v_\xi) := (p - \xi \underline{u}, q - \xi \underline{v})$$

provides us with a T-periodic solution of

$$\begin{cases} u' = \alpha u + \beta v - d, \\ v' = \gamma u + \rho v - \delta. \end{cases} \tag{6.22}$$

Since $p \gg 0$ and $q \gg 0$, we have that $u_\xi \gg 0$ and $v_\xi \gg 0$ for sufficiently small $\xi > 0$. Moreover, since $\underline{u} \gg 0$ and $\underline{v} \gg 0$, we have that $u_\xi \ll 0$ and $v_\xi \ll 0$ for sufficiently large $\xi > 0$. Thus, there exists $\xi > 0$ such that $u_\xi \geqslant 0$, $v_\xi \geqslant 0$ and, for some $t_0 \in \mathbb{R}$, either $u_\xi(t_0) = 0$, or $v_\xi(t_0) = 0$. The result obtained in ending the proof of part (a) shows that this is impossible. It should be noted that $-d \geqslant 0$, $-\delta \geqslant 0$ and $-(\delta + d) > 0$. Therefore, $\nu_2 > 1$, which concludes the proof of the theorem. □

6.2. *Structure of the set of coexistence states*

In this section, the coexistence states of (1.2) will be regarded as zeroes of the operator

$$\mathfrak{F} : \mathbb{R}^2 \times \mathcal{C}_T \times \mathcal{C}_T \to \mathcal{C}_T \times \mathcal{C}_T$$

defined by

$$\mathfrak{F}(\lambda, \mu, u, v) := \begin{pmatrix} u - \mathfrak{R}_M\big[(\lambda\ell + M)u - au^2 - buv\big] \\ v - \mathfrak{R}_M\big[(\mu m + M)v - dv^2 - cuv\big] \end{pmatrix} \tag{6.23}$$

where $M > 0$ is fixed. The following result will provide us with the sharp structure of the whole surface, in terms of the parameters (λ, μ), of the coexistence states of (1.2) linking the surfaces of semi-trivial states of (1.2) along their curves of neutral stability.

PROPOSITION 6.5. *Suppose* $(u_0, v_0) \in \mathcal{C}_T \times \mathcal{C}_T$ *satisfies* $u_0 \gg 0$, $v_0 \gg 0$, *and*

$$\mathfrak{F}(\lambda, \mu, u_0, v_0) = 0.$$

Then, each of the operators

$$D_{(\lambda,u,v)}\mathfrak{F}(\lambda, \mu, u_0, v_0) : \mathbb{R} \times \mathcal{C}_T \times \mathcal{C}_T \to \mathcal{C}_T \times \mathcal{C}_T$$

and

$$D_{(\mu,u,v)}\mathfrak{F}(\lambda, \mu, u_0, v_0) : \mathbb{R} \times \mathcal{C}_T \times \mathcal{C}_T \to \mathcal{C}_T \times \mathcal{C}_T$$

is surjective. In other words, $(0, 0)$ *is a regular value of* $\mathfrak{F}$ *with respect to* $\mathbb{R}^2 \times \operatorname{Int} P \times \operatorname{Int} P$.

PROOF. By differentiating, we have that

$$D_{(u,v)}\mathfrak{F}(\lambda, \mu, u_0, v_0) = I_{\mathcal{C}_T \times \mathcal{C}_T} - \mathfrak{R}_M \begin{pmatrix} \alpha_M & -bu_0 \\ -cv_0 & \beta_M \end{pmatrix}, \tag{6.24}$$

$$D_\lambda\mathfrak{F}(\lambda, \mu, u_0, v_0) = -\mathfrak{R}_M \begin{pmatrix} \ell u_0 \\ 0 \end{pmatrix}, \tag{6.25}$$

and

$$D_\mu\mathfrak{F}(\lambda, \mu, u_0, v_0) = -\mathfrak{R}_M \begin{pmatrix} 0 \\ mv_0 \end{pmatrix}, \tag{6.26}$$

where, for any $\xi \geqslant 0$, we are denoting

$$\alpha_\xi := \lambda\ell + \xi - 2au_0 - bv_0, \quad \beta_\xi := \mu m + \xi - 2dv_0 - cu_0. \tag{6.27}$$

Subsequently, it will be said that (λ,μ,u_0,v_0) is a non-degenerate coexistence state of (1.2) if $D_{(u,v)}\mathfrak{F}(\lambda,\mu,u_0,v_0)$ is an isomorphism. In the contrary case, it will be said that (λ,μ,u_0,v_0) is degenerate.

Obviously, $D_{(\lambda,u,v)}\mathfrak{F}(\lambda,\mu,u_0,v_0)$ and $D_{(\mu,u,v)}\mathfrak{F}(\lambda,\mu,u_0,v_0)$ are surjective if (λ,μ,u_0,v_0) is non-degenerate. So, suppose (λ,μ,u_0,v_0) is degenerate. Then, since $D_{(u,v)}\mathfrak{F}(\lambda,\mu,u_0,v_0)$ is a compact perturbation of the identity, it is Fredholm of index zero and, hence,

$$N := \dim N\big[D_{(u,v)}\mathfrak{F}(\lambda,\mu,u_0,v_0)\big] = \operatorname{codim} R\big[D_{(u,v)}\mathfrak{F}(\lambda,\mu,u_0,v_0)\big] \geqslant 1.$$

Now, note that $N[D_{(u,v)}\mathfrak{F}(\lambda,\mu,u_0,v_0)]$ is the set of T-periodic solutions (u,v) of the linear system

$$\begin{cases} u' = \alpha_0 u - b u_0 v, \\ v' = -c v_0 u + \beta_0 v. \end{cases} \tag{6.28}$$

Since $b<0$ and $c<0$, we have that

$$-bu_0 > 0 \quad \text{and} \quad -cv_0 > 0.$$

Moreover, since (λ,μ,u_0,v_0) is a coexistence state of (1.2), relations (6.7) hold with $(u_2,v_2)=(u_0,v_0)$ and, hence,

$$\int_0^T \alpha_0 = -\int_0^T a(t)u_0(t)\,\mathrm{d}t < 0 \quad \text{and} \quad \int_0^T \beta_0 = -\int_0^T d(t)v_0(t)\,\mathrm{d}t < 0.$$

Therefore, (6.28) fits into the abstract setting of Section 6.1. Consequently, thanks to Theorems 6.1 and 6.3, the biggest multiplier of (6.28), denoted by ν_2, equals one and any T-periodic solution of (6.28) must be a multiple of a fixed T-periodic solution (φ,ψ) such that $\varphi \gg 0$ and $\psi \gg 0$. In particular, $N=1$. So, thanks to (6.25) and (6.26), to conclude the proof it suffices to show the following:

$$\begin{aligned} &-\mathfrak{R}_M(\ell u_0, 0) \notin R\big[D_{(u,v)}\mathfrak{F}(\lambda,\mu,u_0,v_0)\big], \\ &-\mathfrak{R}_M(0, m v_0) \notin R\big[D_{(u,v)}\mathfrak{F}(\lambda,\mu,u_0,v_0)\big]. \end{aligned} \tag{6.29}$$

On the contrary, suppose that, e.g.,

$$-\mathfrak{R}_M(\ell u_0, 0) \in R\big[D_{(u,v)}\mathfrak{F}(\lambda,\mu,u_0,v_0)\big].$$

Then, the system

$$\begin{cases} u' = \alpha_0 u - b u_0 v + \ell u_0, \\ v' = -c v_0 u + \beta_0 v, \end{cases} \tag{6.30}$$

possesses a T-periodic solution, say (u, v). Actually, for each $R > 0$, the pair

$$(u_R, v_R) := (u + R\varphi, v + R\psi)$$

provides us with a T-periodic solution of (6.30). Since $\ell u_0 > 0$, for sufficiently large $R > 0$, (u_R, v_R) provides us with a T-periodic strongly positive strict supersolution of (6.28) and, therefore, thanks to Theorem 6.4(a), $\nu_2 < 1$, which is a contradiction, since $\nu_2 = 1$. Similarly, the second relation of (6.29) holds. This concludes the proof. □

The following result, which is an easy consequence from Proposition 6.5, ascertains the global structure of the components of coexistence states $\mathfrak{C}_\mu^\lambda$ and $\mathfrak{C}_\lambda^\mu$ of (1.2) constructed in Theorems 5.4 and 5.5.

THEOREM 6.6. *The following properties are satisfied*:

(a) *For each* $\lambda > 0$, *the component of coexistence states* $\mathfrak{C}_\mu^\lambda$ *is unbounded in* $\mathbb{R} \times \mathcal{C}_T \times \mathcal{C}_T$ *and it consists of a real analytic curve. More precisely, there exits a real analytic map* $(\mu, u, v) : [0, \infty) \to \mathbb{R} \times \operatorname{Int} P \times \operatorname{Int} P$ *such that*

$$\big(\mu(0), u(0), v(0)\big) = (\mu_0, \theta_{[\lambda\ell,a]}, 0)$$

and

$$\mathfrak{C}_\mu^\lambda = \big\{\big(\mu(s), u(s), v(s)\big) \colon\ s \in (0, \infty)\big\}.$$

(b) *For each* $\mu > 0$, *the component of coexistence states* $\mathfrak{C}_\lambda^\mu$ *is unbounded in* $\mathbb{R} \times \mathcal{C}_T \times \mathcal{C}_T$ *and it consists of a real analytic curve. More precisely, there exists a real analytic map* $(\lambda, u, v) : [0, \infty) \to \mathbb{R} \times \operatorname{Int} P \times \operatorname{Int} P$ *such that*

$$\big(\lambda(0), u(0), v(0)\big) = (\lambda_0, 0, \theta_{[\mu m,d]})$$

and

$$\mathfrak{C}_\lambda^\mu = \big\{\big(\lambda(s), u(s), v(s)\big) \colon\ s \in (0, \infty)\big\}.$$

(c) *The set of coexistence states of* (1.2) $(\lambda, \mu, u, v) \in \mathbb{R}^2 \times \operatorname{Int} P \times \operatorname{Int} P$ *such that* $\lambda > 0$ *and, for some* $\mu \in \mathbb{R}$, $(\mu, u, v) \in \mathfrak{C}_\mu^\lambda$, *or* $\mu > 0$ *and, for some* $\lambda \in \mathbb{R}$, $(\lambda, u, v) \in \mathfrak{C}_\lambda^\mu$ *is a real analytic surface linking the surfaces of semi-trivial states*

$$\big\{(\lambda, \mu, \theta_{[\lambda\ell,a]}, 0) \colon\ \lambda > 0,\ \mu \in \mathbb{R}\big\}$$

and

$$\big\{(\lambda, \mu, 0, \theta_{[\mu m,d]}) \colon\ \lambda \in \mathbb{R},\ \mu > 0\big\}$$

along their respective curves of neutral stability

$$\mu = \frac{1}{T}\int_0^T c(t)\theta_{[\lambda\ell,a]}(t)\,\mathrm{d}t \quad \textit{and} \quad \lambda = \frac{1}{T}\int_0^T b(t)\theta_{[\mu m,d]}(t)\,\mathrm{d}t.$$

PROOF. Suppose (λ, μ, u_0, v_0) is a coexistence state of (1.2) with, e.g., $\lambda > 0$. Subsequently, we fix λ and regard to μ as the main path-following parameter. Suppose (λ, μ, u_0, v_0) is non-degenerate. Then, the implicit function theorem shows that (μ, u_0, v_0) lies in an analytic curve through it that can be locally parameterized by μ, or ... by some length, or pseudo-length of arc of curve, as it is usual in numerical analysis of bifurcation problems. Now, suppose that (λ, μ, u_0, v_0) is degenerate and let $\omega_0 \in \mathbb{R} \times \mathcal{C}_T \times \mathcal{C}_T$ such that

$$N\big[D_{(\mu,u,v)}\mathfrak{F}(\lambda, \mu, u_0, v_0)\big] = \operatorname{span}[\omega_0].$$

Let Z be any closed supplement of ω_0 in $\mathbb{R} \times \mathcal{C}_T \times \mathcal{C}_T$, i.e.,

$$\mathbb{R} \times \mathcal{C}_T \times \mathcal{C}_T = \operatorname{span}[\omega_0] \oplus Z.$$

Then, any element $(\mu, u, v) \in \mathbb{R} \times \mathcal{C}_T \times \mathcal{C}_T$ admits a unique decomposition as

$$(\mu, u, v) = s\omega_0 + z, \qquad (s, z) \in \mathbb{R} \times Z.$$

So, the problem of solving $\mathfrak{F}(\lambda, \mu, u, v) = 0$, with λ fixed, around (μ, u_0, v_0) is equivalent to the problem of solving

$$0 = \mathfrak{G}(s, z) := \mathfrak{F}\big(\lambda, (\mu, u_0, v_0) + s\omega_0 + z\big)$$

around $(s, z) = (0, 0)$. The map $\mathfrak{G} : \mathbb{R} \times Z \to \mathcal{C}_T \times \mathcal{C}_T$ is real analytic and it satisfies $\mathfrak{G}(0, 0) = 0$. Moreover, thanks to Proposition 6.5, the linearized operator

$$D_z\mathfrak{G}(0, 0) = D_{(\mu,u,v)}\mathfrak{F}(\mu, u_0, v_0)|_Z$$

is a linear isomorphism. Therefore, thanks to the implicit function, the set of coexistence states of (1.2) around (λ, μ, u_0, v_0) consists of an analytic curve. Actually, the curve can be parameterized by the projection of the coexistence states on ω_0.

Now, fix $\lambda > 0$. Since $b < 0$, for each $\mu > 0$ we have that

$$\lambda > 0 > \frac{1}{T}\int_0^T b(t)\theta_{[\mu m,d]}(t)\,\mathrm{d}t$$

and, therefore, thanks to Theorem 5.4, $\mathfrak{C}_\mu^\lambda$ is unbounded. Moreover, thanks to Theorem 5.6, there exists $L > 0$ and a real analytic map

$$(\mu, u, v) : [0, L] \to \mathbb{R} \times \operatorname{Int} P \times \operatorname{Int} P$$

such that

$$\big(\mu(0), u(0), v(0)\big) = (\mu_0, \theta_{[\lambda\ell,a]}, 0)$$

and, in a neighborhood of $(\mu_0, \theta_{[\lambda\ell,a]}, 0)$, $\mathfrak{C}^\lambda_\mu$ consists of

$$\big\{\big(\mu(s), u(s), v(s)\big)\colon\ 0 < s \leqslant L\big\}.$$

By a global continuation argument based on the implicit function theorem, the *local curve* $(\mu(s), u(s), v(s))$, $s \in (0, L]$, admits a *maximal continuation* (non-prolonging) to a real analytic curve, $(\mu(s), u(s), v(s))$, $s \in (0, \infty)$, of coexistence states of (1.2). Actually, the parameter s can be taken as the length of arc of curve. Clearly,

$$\varGamma := \big\{\big(\mu(s), u(s), v(s)\big)\colon\ s > 0\big\} \subset \mathfrak{C}^\lambda_\mu,$$

since $\mathfrak{C}^\lambda_\mu$ is connected. Moreover, the uniqueness obtained as an application of the implicit function theorem shows that there exists an open subset $\mathcal{O} \subset \mathbb{R} \times \mathcal{C}_T \times \mathcal{C}_T$ such that

$$\varGamma \subset \mathcal{O} \quad \text{and} \quad \mathfrak{F}^{-1}(0) \cap (\mathbb{R} \times \operatorname{Int} P \times \operatorname{Int} P) \cap \mathcal{O} = \varGamma.$$

Therefore, $\mathfrak{C}^\lambda_\mu = \varGamma$, since $\mathfrak{C}^\lambda_\mu$ is connected. Part (b) follows from the symmetry of the problem. part (c) is a two-parameter re-interpretation of parts (a) and (b) that can be easily obtained from the fact that $\mathfrak{F}$ is real analytic in all its arguments. This concludes the proof. □

For the autonomous counterpart of (1.2) with $bc = 1$, is very simple to check that, for each $\lambda > 0$, the curve

$$\big(\mu(s), u(s), v(s)\big) = (c\lambda, \lambda - bs, s), \qquad s \geqslant 0,$$

provides us with the component $\mathfrak{C}^\lambda_\mu$ bifurcating from the semi-trivial solution $(\lambda, 0)$ at $\mu = c\lambda$. As this simple example shows, in general, condition $\mu' = 0$ cannot be avoided unless some additional assumptions are made, as, e.g., having a priori bounds for the coexistence states of the model at $\mu = \mu_0$. Note that in case $\mu' = 0$, one necessarily has $\mu(s) = \mu_0$ for each $s \geqslant 0$ and

$$\limsup_{s\uparrow\infty} \big\|\big(u(s), v(s)\big)\big\|_{\mathcal{C}_T\times\mathcal{C}_T} = \infty,$$

since $\mathfrak{C}^\lambda_\mu$ is unbounded. Actually, as an immediate consequence from the analysis carried out in the next section, in case $\mu' = 0$ one has that, for each $s \geqslant 0$, $\dot{u}(s) \gg 0$ and $\dot{v}(s) \gg 0$, where $\cdot := \frac{\mathrm{d}}{\mathrm{d}s}$. Therefore,

$$\lim_{s\uparrow\infty} \big\|\big(u(s), v(s)\big)\big\|_{\mathcal{C}_T\times\mathcal{C}_T} = \infty.$$

6.3. *Stability of the coexistence states along $\mathfrak{C}^{\lambda}_{\mu}$ and $\mathfrak{C}^{\mu}_{\lambda}$*

Fix $\lambda > 0$ and let $(\mu(s), u(s), v(s))$, $s \geqslant 0$, be the real analytic map constructed in Theorem 6.6, where s is assumed to be the length of arc of curve. Subsequently, we shall denote $\cdot := \frac{\mathrm{d}}{\mathrm{d}s}$. Since

$$\mathfrak{F}\big(\lambda, \mu(s), u(s), v(s)\big) = 0, \quad s \geqslant 0,$$

differentiating with respect to s gives

$$D_{(\mu,u,v)}\mathfrak{F}\big(\lambda, \mu(s), u(s), v(s)\big)\big(\dot{\mu}(s), \dot{u}(s), \dot{v}(s)\big) = 0, \quad s > 0, \tag{6.31}$$

and, hence,

$$N\big[D_{(\mu,u,v)}\mathfrak{F}\big(\lambda, \mu(s), u(s), v(s)\big)\big] = \operatorname{span}\big[\big(\dot{\mu}(s), \dot{u}(s), \dot{v}(s)\big)\big], \quad s > 0.$$

Moreover, since s has been taken as the length of arc of curve,

$$\big\|\big(\dot{\mu}(s), \dot{u}(s), \dot{v}(s)\big)\big\|_{\mathbb{R}\times\mathcal{C}_T\times\mathcal{C}_T} = 1, \quad s > 0. \tag{6.32}$$

On the other hand, since

$$\big(\mu(0), u(0), v(0)\big) = (\mu_0, \theta_{[\lambda\ell,a]}, 0),$$

it follows from Theorem 5.6 that

$$\dot{v}(s) = \varphi_v + \mathrm{O}(s) = \mathrm{e}^{\int_0^{\cdot}(\mu_0 m - c\theta_{[\lambda\ell,a]})} + \mathrm{O}(s) \gg 0, \quad s \downarrow 0. \tag{6.33}$$

Now, set

$$(p_s, q_s) := \big(\dot{u}(s), \dot{v}(s)\big), \quad s > 0,$$

and note that (6.31) can be equivalently rewritten in the form

$$\begin{cases} (p_s)' = \big[\lambda\ell - 2au(s) - bv(s)\big]p_s - bu(s)q_s, \\ (q_s)' = -cv(s)p_s + \big[\mu(s)m - 2dv(s) - cu(s)\big]q_s + \dot{\mu}(s)mv(s). \end{cases} \tag{6.34}$$

Note that, since $-bu(s) > 0$, $-cv(s) > 0$,

$$\int_0^T \big[\lambda\ell - 2au(s) - bv(s)\big] = -2\int_0^T \big[au(s)\big] < 0, \tag{6.35}$$

and

$$\int_0^T \big[\mu(s)m - 2dv(s) - cu(s)\big] = -2\int_0^T \big[dv(s)\big] < 0, \tag{6.36}$$

the linear system (6.34) fits within the general setting of Section 6.1. In particular, thanks to Proposition 2.1, we find from the first equation of (6.34) that, for each $s > 0$ sufficiently small,

$$p_s = \mathfrak{R}_{-[\lambda\ell - 2au(s) - bv(s)]}\bigl(-bu(s)q_s\bigr) \gg 0.$$

Therefore, there exists $\varepsilon > 0$ such that

$$p_s \gg 0 \quad \text{and} \quad q_s \gg 0 \quad \text{for each } s \in [0, \varepsilon]. \tag{6.37}$$

Suppose $\mu = \mu_0$ for each $s \geqslant 0$. Then, (6.34) becomes into

$$\begin{cases} (p_s)' = \bigl[\lambda\ell - 2au(s) - bv(s)\bigr]p_s - bu(s)q_s, \\ (q_s)' = -cv(s)p_s + \bigl[\mu(s)m - 2dv(s) - cu(s)\bigr]q_s. \end{cases} \tag{6.38}$$

Thanks to (6.32), $(p_s, q_s) \neq (0, 0)$ and, hence, thanks to Theorem 6.1, for each $s \geqslant 0$, either $p_s \gg 0$ and $q_s \gg 0$, or $p_s \ll 0$ and $q_s \ll 0$. Thanks to (6.37), necessarily

$$p_s \gg 0 \quad \text{and} \quad q_s \gg 0 \quad \text{for each } s \in [0, \infty). \tag{6.39}$$

Indeed, since $s \to (p_s, q_s)$ is real analytic, if (6.39) is not satisfied, then, due to (6.37), there is some value of s, say $\tilde{s} > 0$, where $p_{\tilde{s}} > 0$, $q_{\tilde{s}} > 0$, and, e.g., $p_{\tilde{s}} \gg 0$ fails. Thanks to Theorem 6.1, this would imply $p_{\tilde{s}} \gg 0$ and $q_{\tilde{s}} \gg 0$, which is a contradiction. Thus, (6.39) is satisfied, as it was claimed in the last paragraph of Section 6.2, and, consequently, thanks to Theorem 6.3, the principal characteristic multiplier of $(\mu(s), u(s), v(s))$, which will be subsequently denoted by $\nu_2(s)$, satisfies $\nu_2(s) = 1$ for each $s \geqslant 0$. Therefore, if $\dot{\mu} = 0$, then $\dot{\nu}_2 = 0$ and, hence, all the coexistence states of $\mathfrak{C}^{\lambda}_{\mu}$ are neutrally stable. When $\dot{\mu} \neq 0$, then the following result is satisfied.

THEOREM 6.7. *Suppose $\dot{\mu} \neq 0$ in $[0, \infty)$. Then, the set*

$$\mathcal{S} := \bigl\{s \in (0, \infty)\colon\ \dot{\mu}(s) = 0\bigr\} \tag{6.40}$$

is discrete, each $s \in \mathcal{S}$ is a zero of finite order of $\dot{\mu}$, and

$$\mathcal{S} = \bigl\{s \in (0, \infty)\colon\ \nu_2(s) = 1\bigr\}. \tag{6.41}$$

Moreover,

$$\dot{\mu}(s)\bigl(1 - \nu_2(s)\bigr) > 0, \quad s \in (0, \infty) \setminus \mathcal{S}, \tag{6.42}$$

and

$$p_s \gg 0 \quad \textit{and} \quad q_s \gg 0 \quad \textit{if} \quad \dot{\mu}(s) \geqslant 0. \tag{6.43}$$

PROOF. The fact that $\mathcal{S}$ is discrete and that each $s \in \mathcal{S}$ has finite order, as a zero of $\dot{\mu}$, are consequences from the fact that $\dot{\mu}$ is real analytic. Now, we shall prove (6.41). Pick $s \in \mathcal{S}$. Then, (p_s, q_s) satisfies (6.38) and, due to (6.32), $(p_s, q_s) \neq (0, 0)$. Thus, thanks to Theorem 6.1, $p_s \gg 0$ and $q_s \gg 0$, or $p_s \ll 0$ and $q_s \ll 0$. In any of these cases, it follows from Theorem 6.3 that $\lambda = 0$ is the *principal characteristic exponent* of $(\mu(s), u(s), v(s))$ and, hence, $\nu_2(s) = 1$. To prove the converse inclusion, let $s \in (0, \infty)$ such that $\nu_2(s) = 1$. Then, thanks to Theorem 6.3, there exists a T-periodic pair (P, Q) with $P \gg 0$ and $Q \gg 0$ such that

$$\begin{cases} P' = \big[\lambda\ell - 2au(s) - bv(s)\big]P - bu(s)Q, \\ Q' = -cv(s)P + \big[\mu(s)m - 2dv(s) - cu(s)\big]P. \end{cases} \tag{6.44}$$

Now, choose a sufficiently small $\varepsilon > 0$ so that the auxiliary pair

$$(U, V) := (P - \varepsilon p_s, Q - \varepsilon q_s),$$

satisfy $U \gg 0$ and $V \gg 0$. Thanks to (6.34) and (6.44) we have that

$$\begin{cases} U' = \big[\lambda\ell - 2au(s) - bv(s)\big]U - bu(s)V, \\ V' = -cv(s)U + \big[\mu(s)m - 2dv(s) - cu(s)\big]V - \varepsilon\dot{\mu}(s)mv(s). \end{cases}$$

Assume $\dot{\mu}(s) > 0$. Then, since $\varepsilon mv(s) > 0$, (U, V) is a strict subsolution of

$$\begin{cases} x' = \big[\lambda\ell - 2au(s) - bv(s)\big]x - bu(s)y, \\ y' = -cv(s)x + \big[\mu(s)m - 2dv(s) - cu(s)\big]y, \end{cases} \tag{6.45}$$

and, hence, thanks to Theorem 6.4(b), $\nu_2(s) > 1$, which is a contradiction. Assume $\dot{\mu}(s) < 0$. Then, (U, V) is a strict supersolution of (6.45) and, due to Theorem 6.4(a), $\nu_2(s) < 1$, which is a contradiction again. Consequently, $\dot{\mu}(s) = 0$ and, therefore, (6.41) holds.

Now, pick $\tilde{s} \in \mathcal{S}$. Thanks to (6.32), it follows from Theorem 6.1 that some of the following alternatives occurs:

1. $p_{\tilde{s}} \gg 0$ and $q_{\tilde{s}} \gg 0$.
2. $p_{\tilde{s}} \ll 0$ and $q_{\tilde{s}} \ll 0$.

Assume alternative 1 occurs. As $\tilde{s}$ is an isolated zero of $\dot{\mu}(s)$, there exists $\varepsilon > 0$ such that $p_s = \dot{u}(s) \gg 0$ and $q_s = \dot{v}(s) \gg 0$ for each $s \in (\tilde{s} - \varepsilon, \tilde{s} + \varepsilon)$, and

$$\dot{\mu}^{-1}(0) \cap \big(\tilde{s} - \varepsilon, \tilde{s} + \varepsilon\big) \cap (0, \infty) = \big\{\tilde{s}\big\}.$$

Thus, for each

$$s \in J := (0, \infty) \cap \big[\big(\tilde{s} - \varepsilon, \tilde{s} + \varepsilon\big) \setminus \big\{\tilde{s}\big\}\big],$$

either $\dot{\mu}(s) > 0$, or $\dot{\mu}(s) < 0$. Suppose $\dot{\mu}(s) > 0$. Then, (p_s, q_s) provides us with a strongly positive strict supersolution of (6.45) and it follows from Theorem 6.4(a) that $\nu_2(s) < 1$.

Hence, $\dot{\mu}(s)(1-\nu_2(s))>0$. Now, suppose $\dot{\mu}(s)<0$. Then, (p_s,q_s) provides us with a strongly positive strict subsolution of (6.45) and it follows from Theorem 6.4(b) that $\nu_2(s)>1$. Hence, $\dot{\mu}(s)(1-\nu_2(s))>0$. Therefore, condition (6.42) is satisfied for each $\tilde{s}\in\mathcal{S}$ satisfying alternative 1.

Now, suppose $\tilde{s}\in\mathcal{S}$ satisfies alternative 2. As $\tilde{s}$ is an isolated zero of $\dot{\mu}(s)$, there exists $\varepsilon>0$ such that $p_s=\dot{u}(s)\ll 0$ and $q_s=\dot{v}(s)\ll 0$ for each $s\in(\tilde{s}-\varepsilon,\tilde{s}+\varepsilon)$, and

$$\dot{\mu}^{-1}(0)\cap\big(\tilde{s}-\varepsilon,\tilde{s}+\varepsilon\big)\cap(0,\infty)=\big\{\tilde{s}\big\}.$$

Thus, for each

$$s\in J:=(0,\infty)\cap\big[\big(\tilde{s}-\varepsilon,\tilde{s}+\varepsilon\big)\setminus\big\{\tilde{s}\big\}\big],$$

either $\dot{\mu}(s)>0$, or $\dot{\mu}(s)<0$. Suppose $\dot{\mu}(s)>0$. Then, $(-p_s,-q_s)$ provides us with a strongly positive strict subsolution of (6.45) and it follows from Theorem 6.4(b) that $\nu_2(s)>1$. Hence, $\dot{\mu}(s)(1-\nu_2(s))<0$. Similarly, if $\dot{\mu}(s)<0$, then, $(-p_s,-q_s)$ provides us with a strongly positive strict supersolution of (6.45) and Theorem 6.4(a) implies $\nu_2(s)<1$. Therefore, the following condition is satisfied

$$\dot{\mu}(s)\big(1-\nu_2(s)\big)<0,\quad s\in(0,\infty)\cap\big[\big(\tilde{s}-\varepsilon,\tilde{s}+\varepsilon\big)\setminus\big\{\tilde{s}\big\}\big],\tag{6.46}$$

for each $\tilde{s}\in\mathcal{S}$ satisfying alternative 2.

Now, suppose

$$\mathcal{S}=\{s_n\colon n\geqslant 1\},\quad 0<s_1<s_n<s_{n+1},\ n\geqslant 2;$$

the subsequent argument can be easily adapted to cover the case when $\mathcal{S}$ is finite, possibly empty. Thanks to (6.37), for sufficiently small $s>0$, $p_s\gg 0$ and $q_s\gg 0$. Moreover, either $\dot{\mu}(s)>0$ for each $s\in(0,s_1)$, or $\dot{\mu}(s)<0$ for each $s\in(0,s_1)$.

Suppose $\dot{\mu}(s)>0$ for each $s\in(0,s_1)$. Then, for sufficiently small $s>0$, (p_s,q_s) provides us with a strongly positive strict supersolution of (6.45) and, hence, thanks to Theorem 6.4(a), $\nu_2(s)<1$. Actually, this is the inter-exchange stability principle between the semi-trivial state $(\mu,\theta_{[\lambda\ell,a]},0)$ and the bifurcating coexistence state $(\mu(s),u(s),v(s))$ as μ crosses μ_0. Thanks to (6.41), necessarily $\nu_2(s)<1$ for every $s\in(0,s_1)$ and, therefore,

$$\dot{\mu}(s)\big(1-\nu_2(s)\big)>0,\quad s\in(0,s_1).\tag{6.47}$$

Necessarily $p_{s_1}\gg 0$ and $q_{s_1}\gg 0$. Indeed, if $p_{s_1}\ll 0$ and $q_{s_1}\ll 0$, then (6.46) holds, which contradicts (6.47). Therefore,

$$\dot{\mu}(s)\big(1-\nu_2(s)\big)>0,\quad s\in(0,s_2)\setminus\{s_2\}.\tag{6.48}$$

Reiterating this argument, (6.42) holds readily.

Now, suppose $\dot{\mu}(s)<0$ for each $s\in(0,s_1)$. Then, (p_s,q_s) provides us with a strongly positive strict subsolution of (6.45) and, hence, thanks to Theorem 6.4(b), $\nu_2(s)>1$. As in the previous case, this provides us with the inter-exchange stability principle between the semi-trivial state $(\mu, \theta_{[\lambda\ell,a]}, 0)$ and the bifurcating coexistence state $(\mu(s), u(s), v(s))$. Thanks to (6.41), $\nu_2(s) > 1$ for every $s \in (0, s_1)$ and, therefore, (6.47) is as well satisfied. Arguing as above, the proof of (6.42) is concluded.

Note that, as a result from the previous analysis, we have that

$$p_{\tilde{s}} \gg 0 \quad \text{and} \quad q_{\tilde{s}} \gg 0 \quad \text{for each } \tilde{s} \in \mathcal{S} \cup \{0\}. \tag{6.49}$$

Let $s_1^*, s_2^* \in \mathcal{S} \cup \{0\}$ such that

$$\dot{\mu}(s) > 0, \quad s \in \left(s_1^*, s_2^*\right).$$

Thanks to (6.49), $p_s \gg 0$ and $q_s \gg 0$ for each $s > s_1^*$ sufficiently close to s_1^*. Thus, either $p_s \gg 0$ and $q_s \gg 0$ for each $s \in (s_1^*, s_2^*)$, or there exist $s_0 \in (s_1^*, s_2^*)$ and $t \in \mathbb{R}$ such that $p_{s_0} \geqslant 0$ and $q_{s_0} \geqslant 0$ and either $p_{s_0}(t) = 0$, or $q_{s_0}(t) = 0$. Since

$$-cv(s_0)p_{s_0} + \dot{\mu}(s_0)mv(s_0) > 0,$$

thanks to Proposition 2.1, it follows from the second equation of (6.34) that $q_{s_0} \gg 0$. Thus,

$$-bu(s_0)q_{s_0} > 0$$

and, thanks again to Proposition 2.1, the first equation of (6.34) gives $p_{s_0} \gg 0$, which is impossible. Therefore, for each $s \in (s_1^*, s_2^*)$, $p_s \gg 0$ and $q_s \gg 0$, which concludes the proof of (6.43). The proof is completed. □

It should be noted that, since the dependence of the Poincaré map of (6.45) on s is analytic, the map $s \to \nu_2(s)$ is as well real analytic. Moreover,

$$\nu_2(0) = 1,$$

because this is the critical value of the parameter where the stability of the semi-trivial state changes. As far as to $\dot{\mu}(0)$ concerns, it might take any real value, according with the value of the integral of (5.53).

Subsequently, we shall assume

$$\dot{\mu} \neq 0$$

in order to use Theorem 6.7 for ascertaining the attractive character of all the coexistence states along the curve $\mathfrak{C}_\mu^\lambda$. In this case, setting

$$s_1 = \min \mathcal{S},$$

some of the following alternatives occurs. Either

$$\dot{\mu}(s) > 0, \quad s \in (0, s_1) \tag{6.50}$$

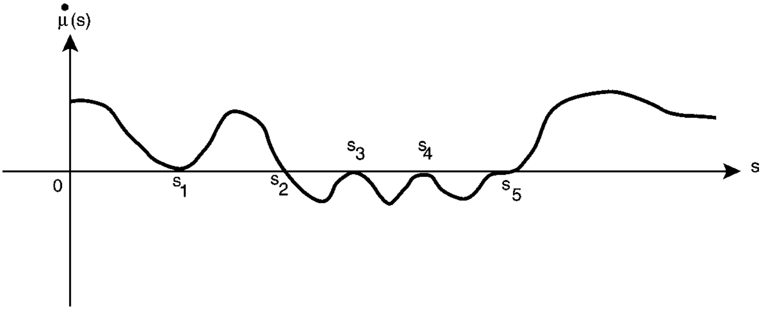

Fig. 11. An admissible graph of $\dot\mu(s)$ in case (6.50).

or

$$\dot\mu(s) < 0, \quad s \in (0, s_1). \tag{6.51}$$

If $\mathcal{S} = \emptyset$, then either $\dot\mu(s) > 0$ for each $s > 0$, or $\dot\mu(s) < 0$ for each $s > 0$. The bifurcation of $\mathfrak{C}^\lambda_\mu$ from $(\mu_0, \theta_{[\lambda\ell,a]}, 0)$ is said to be *super-critical* if (6.50) occurs, while it is said to be *sub-critical* if (6.51) is satisfied.

The following concepts will be extremely useful in the forthcoming discussion. Given $\tilde s \in \mathcal{S}$, we shall denote by $\operatorname{ord}(\tilde s)$ the order of $\tilde s$ as a zero of $\dot\mu(s)$.

- A value $\tilde s \in \mathcal{S}$ is said to be a *hysteresis point* of $\mathfrak{C}^\lambda_\mu$ if $\operatorname{ord}(\tilde s)$ is even.
- A value $\tilde s \in \mathcal{S}$ is said to be a *super-critical turning point* of $\mathfrak{C}^\lambda_\mu$ if $\operatorname{ord}(\tilde s)$ is odd and $\mu(s) > \mu(\tilde s)$ in a perforated neighborhood of $\tilde s$.
- A value $\tilde s \in \mathcal{S}$ is said to be a *sub-critical turning point* of $\mathfrak{C}^\lambda_\mu$ if $\operatorname{ord}(\tilde s)$ is odd and $\mu(s) < \mu(\tilde s)$ in a perforated neighborhood of $\tilde s$.

Suppose (6.50) and, e.g., the graph of $\dot\mu(s)$ is of the type sketched in Fig. 11. Although far from necessary we shall assume that $\mathcal{S} = \{s_1, s_2, s_3, s_4, s_5\}$. Hence, $\dot\mu(s) > 0$ for each $s > s_5$. For this special configuration, s_1, s_3 and s_4 are hysteresis points, while s_2 is a sub-critical turning point and s_5 is a super-critical turning point. Thanks to Theorem 6.7, the principal characteristic multiplier $\nu_2(s)$ of the coexistence state $(\mu(s), u(s), v(s))$ must adjust to the pattern shown in Fig. 12. Therefore, the coexistence state $(\mu(s), u(s), v(s))$ is asymptotically stable if $s \in (0, s_1) \cup (s_1, s_2) \cup (s_5, \infty)$, whereas it is unstable if $s \in (s_2, s_5) \setminus \{s_3, s_4\}$. In Fig. 13 we have represented the corresponding bifurcation diagram of coexistence states, where we are representing the value of $u(t)$ for a given time $t \in \mathbb{R}$ versus the parameter μ, not s. Except for $(\mu, 0, 0)$, continuous lines represent stable solutions, while dashed lines represent unstable solutions. The horizontal lines represent the curves of states $(\mu, 0, 0)$ and $(\mu, \theta_{[\lambda\ell,0]}, 0)$. The curve $\mathfrak{C}^\lambda_\mu$ bifurcates from $(\mu, \theta_{[\lambda\ell,a]}, 0)$ at

$$\mu = \mu_0 = \frac{1}{T}\int_0^T c(t)\theta_{[\lambda\ell,a]}(t)\,\mathrm{d}t < 0,$$

since $c < 0$. The wiggled thick line represent $\mathfrak{C}^\lambda_\mu$, whose bifurcation from the semi-trivial state is super-critical. At the sub-critical turning point $(\mu(s_2), u(s_2), v(s_2))$ the stability of

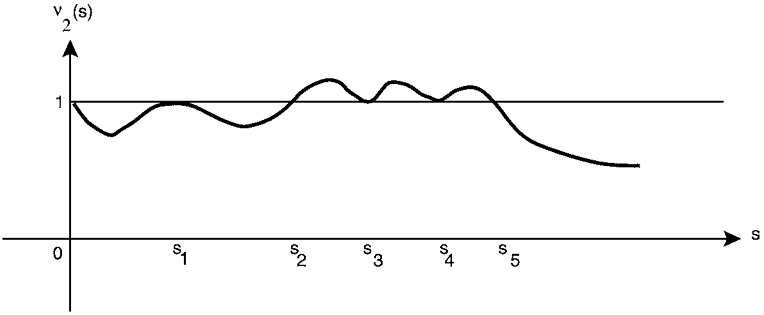

Fig. 12. The corresponding principal characteristic multiplier $\nu_2(s)$.

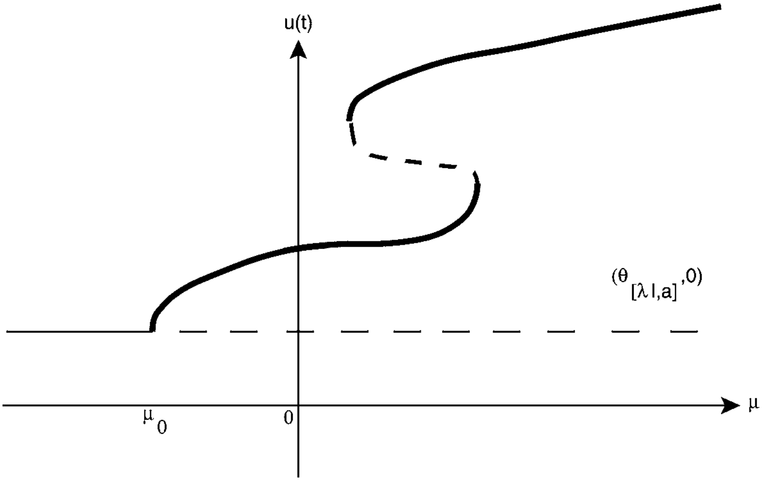

Fig. 13. The corresponding bifurcation diagram.

the solutions along the lower arc of curve of $\mathfrak{C}^\lambda_\mu$ is lost. Then, the solutions stay unstable until the second turning point, $(\mu(s_5), u(s_5), v(s_5))$, which is super-critical, is passed by. Once crossed the super-critical turning point, all remaining solutions for further values of s stay stable. It should be noted that, thanks to Theorem 6.7, $u(s)$ and $v(s)$ are strongly increasing along the pieces of the curve $\mathfrak{C}^\lambda_\mu$ where $\dot\mu(s) \geqslant 0$.

Now, suppose (6.51), instead of (6.50), and, e.g., the graph of $\dot\mu(s)$ adjust to the profile shown in Fig. 14. According to Theorem 6.7, the principal characteristic multiplier $\nu_2(s)$ of the coexistence state $(\mu(s), u(s), v(s))$ must adjust to the pattern shown in Fig. 15. In Fig. 16 we have represented an admissible bifurcation diagram corresponding to the graph of $\dot\mu(s)$ shown in Fig. 14. Now the bifurcation of $\mathfrak{C}^\lambda_\mu$ from $(\mu, \theta_{[\lambda\ell,a]}, 0)$ at μ_0 is sub-critical, the solutions along the lower curve being unstable until they reach the super-critical turning point $(\mu(s_2), u(s_2), v(s_2))$, where they become stable until reaching the second turning point, $(\mu(s_5), u(s_5), v(s_5))$, where they become unstable and stay unstable for any further value of s, $s > s_5$.

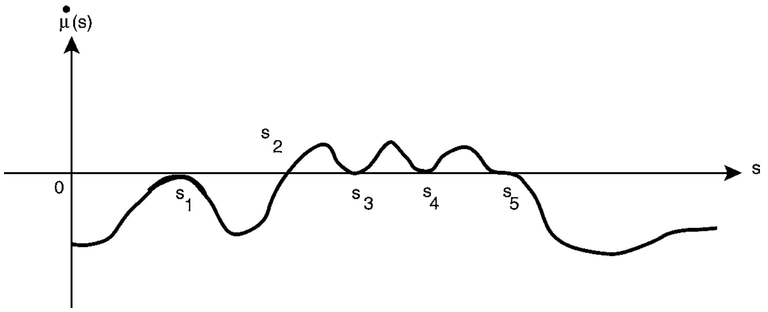

Fig. 14. An admissible graph for $\dot{\mu}(s)$ in case (6.51).

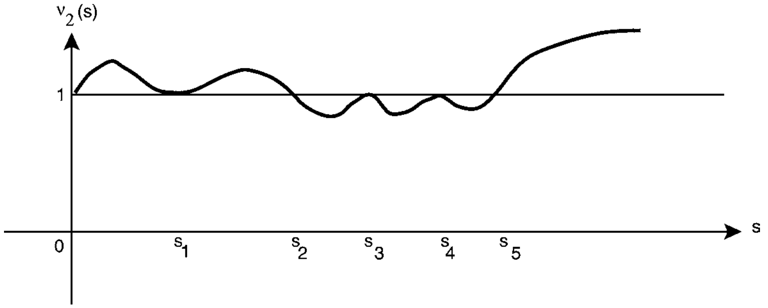

Fig. 15. The corresponding principal characteristic multiplier $\nu_2(s)$.

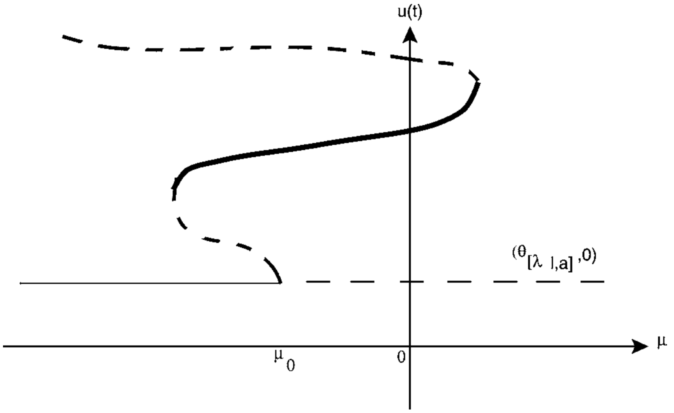

Fig. 16. The corresponding bifurcation diagram.

As in the previous example, as a result of Theorem 6.7, $s \mapsto (u(s), v(s))$ is strongly increasing along any arc of curve filled in by stable solutions, though some of the components might decrease along some pieces of the arcs of curve where the coexistence states are unstable.

Generically, when some additional parameter of the model is varied, each hysteresis point will either disappear, or it will generate an even number of turning points; half among them sub-critical and the other half super-critical. This might provide with a mechanism to generate models with an arbitrarily large number of coexistence states.

It should be noted that (1.2) might possess some additional coexistence state not lying in $\mathfrak{C}_\mu^\lambda$. If this is the case, i.e., if (1.2) possesses a coexistence state $(\mu, u_0, v_0) \notin \mathfrak{C}_\mu^\lambda$, then the global continuation argument used to ascertain the analytic structure of $\mathfrak{C}_\mu^\lambda$ also shows that there is an analytic curve

$$(\mu, u, v) : (-\infty, \infty) \to \mathbb{R} \times \mathcal{C}_T \times \mathcal{C}_T$$

of coexistence states of (1.2) such that

$$\big(\mu(0), u(0), v(0)\big) = (\mu, u_0, v_0)$$

and $\dot{\mu} \neq 0$. Indeed, if $\dot{\mu} = 0$, then $\mu(s) = \mu$ for each s, and $s \mapsto (u(s), v(s))$ must be strongly monotone, and, as a result, it should bifurcate from $(\mu_0, \theta_{[\lambda\ell, a]}, 0)$, which is not possible, because $(\mu, u_0, v_0) \notin \mathfrak{C}_\mu^\lambda$. Theorem 6.7 also applies along these curves, showing that $\nu_2(s) - 1$ must change of sign at any turning point along them. The corresponding curves should be either isolated bounded components, or unbounded components, but a sharper analysis of this and other related problems escapes from the general scope of this chapter.

By symmetry, all the results that we have obtained for $\mathfrak{C}_\mu^\lambda$ are also valid for the components $\mathfrak{C}_\lambda^\mu$ obtained by fixing $\mu > 0$ and using λ as the main bifurcation parameter.

6.4. *Low and strong symbiosis effects*

Throughout this section we will assume that

$$\ell \gg 0, \quad m \gg 0, \quad a \gg 0, \quad d \gg 0, \quad -b \gg 0, \quad -c \gg 0. \tag{6.52}$$

Then, it is said that (1.2) is lowly symbiotic if

$$\left(\frac{-b}{a}\right)_M \left(\frac{-c}{d}\right)_M < 1, \tag{6.53}$$

while it is said that (1.2) is highly symbiotic if

$$\left(\frac{-b}{a}\right)_L \left(\frac{-c}{d}\right)_L > 1. \tag{6.54}$$

Although in the intermediate situation cases where conditions (6.53) and (6.54) fail, the curves of coexistence states $\mathfrak{C}_\mu^\lambda$ and $\mathfrak{C}_\lambda^\mu$ might exhibit a bounded μ projection and a bounded λ projection, respectively, because of the lost of uniform priori bounds in $\mathcal{C}_T \times \mathcal{C}_T$, in the cases when some of these conditions is satisfied, the μ and λ-projections are unbounded. Actually, the following result is satisfied for the case of low symbiosis.

THEOREM 6.8. *Assume* (6.52), (6.53), *and* (1.2) *possesses a coexistence state, say* (λ, μ, u, v). *Then,*

$$\begin{aligned} &\lambda \geqslant -(-b/\ell)_M (m/d)_M \mu \quad \text{if } \mu > 0, \\ &\mu \geqslant -(-c/m)_M (\ell/a)_M \lambda \quad \text{if } \lambda > 0. \end{aligned} \tag{6.55}$$

Moreover,

$$\begin{aligned} \|u\|_{\mathcal{C}_T} &\leqslant \frac{(\ell/a)_M |\lambda| + (-b/a)_M (m/d)_M |\mu|}{1 - (-b/a)_M (-c/d)_M}, \\ \|v\|_{\mathcal{C}_T} &\leqslant \frac{(m/d)_M |\mu| + (-c/d)_M (\ell/a)_M |\lambda|}{1 - (-b/a)_M (-c/d)_M}, \end{aligned} \tag{6.56}$$

and, therefore, for each $\lambda > 0$ *and* $\mu > 0$ *there exist*

$$\mu_1 = \mu_1(\lambda) \in (-\infty, \mu_0] \quad \text{and} \quad \lambda_1 = \lambda_1(\mu) \in (-\infty, \lambda_0]$$

such that

$$P_\mu \mathfrak{C}^\lambda_\mu \in \{[\mu_1, \infty), (\mu_0, \infty)\} \quad \text{and} \quad P_\lambda \mathfrak{C}^\mu_\lambda \in \{[\lambda_1, \infty), (\lambda_0, \infty)\},$$

where P_γ *stands for the* γ*-projection operator,* $\gamma \in \{\lambda, \mu\}$.

PROOF. Pick $t_0, t_1 \in \mathbb{R}$ such that

$$u(t_0) = \|u\|_{\mathcal{C}_T} \quad \text{and} \quad v(t_1) = \|v\|_{\mathcal{C}_T}.$$

Then, $u'(t_0) = v'(t_1) = 0$ and, hence,

$$\lambda \ell(t_0) - a(t_0)u(t_0) - b(t_0)v(t_0) = 0, \qquad \mu m(t_1) - d(t_1)v(t_1) - c(t_1)u(t_1) = 0.$$

Thus,

$$u(t_0) = \lambda \frac{\ell(t_0)}{a(t_0)} - \frac{b(t_0)}{a(t_0)} v(t_0), \qquad v(t_1) = \mu \frac{m(t_1)}{d(t_1)} - \frac{c(t_1)}{d(t_1)} u(t_1). \tag{6.57}$$

Now, since

$$v(t_0) \leqslant v(t_1) = \mu \frac{m(t_1)}{d(t_1)} - \frac{c(t_1)}{d(t_1)} u(t_1) \leqslant \mu \frac{m(t_1)}{d(t_1)} - \frac{c(t_1)}{d(t_1)} u(t_0),$$

the first identity of (6.57) implies

$$u(t_0) \leqslant \frac{\ell(t_0)}{a(t_0)}\lambda - \frac{b(t_0)}{a(t_0)}\frac{m(t_1)}{d(t_1)}\mu + \frac{b(t_0)}{a(t_0)}\frac{c(t_1)}{d(t_1)}u(t_0)$$

and, hence,

$$\left[1 - \frac{b(t_0)}{a(t_0)}\frac{c(t_1)}{d(t_1)}\right]u(t_0) \leqslant \frac{\ell(t_0)}{a(t_0)}\lambda - \frac{b(t_0)}{a(t_0)}\frac{m(t_1)}{d(t_1)}\mu. \tag{6.58}$$

Similarly,

$$\left[1 - \frac{b(t_0)}{a(t_0)}\frac{c(t_1)}{d(t_1)}\right]v(t_1) \leqslant \frac{m(t_1)}{d(t_1)}\mu - \frac{c(t_1)}{d(t_1)}\frac{\ell(t_0)}{a(t_0)}\lambda. \tag{6.59}$$

Moreover, thanks to (6.53),

$$0 < 1 - \left(\frac{-b}{a}\right)_M \left(\frac{-c}{d}\right)_M \leqslant 1 - \frac{b(t_0)}{a(t_0)}\frac{c(t_1)}{d(t_1)} \tag{6.60}$$

and, consequently, it follows from (6.58) and (6.59) that, necessarily,

$$\lambda \geqslant -\frac{-b(t_0)}{\ell(t_0)}\frac{m(t_1)}{d(t_1)}\mu \quad \text{and} \quad \mu \geqslant -\frac{-c(t_1)}{m(t_1)}\frac{\ell(t_0)}{a(t_0)}\lambda.$$

Therefore, (6.55) are necessary conditions for the existence of a coexistence state. Also, substituting (6.60) into (6.58) and (6.59), gives (6.56).

Now, fix $\lambda > 0$ and consider the analytic curve $\mathfrak{C}^{\lambda}_{\mu}$. Thanks to Theorem 6.6(a), $\mathfrak{C}^{\lambda}_{\mu}$ is unbounded in $\mathbb{R} \times \mathcal{C}_T \times \mathcal{C}_T$. Thus, thanks to the uniform a priori estimates (6.56), $P_\mu \mathfrak{C}^{\lambda}_{\mu}$ must be unbounded. Note that it is connected, since $\mathfrak{C}^{\lambda}_{\mu}$ is a curve. Therefore, the conclusion follows from the second necessary condition of (6.55). Similarly, one can obtain the corresponding assertion for $\mathfrak{C}^{\mu}_{\lambda}$. □

As a consequence from Theorem 6.8, for each $\lambda > 0$, the curve $\mathfrak{C}^{\lambda}_{\mu}$ looks like the one shown in Fig. 13, whereas, for the case of strong symbiosis, the following result shows that $\mathfrak{C}^{\lambda}_{\mu}$ looks like shows Fig. 16.

THEOREM 6.9. *Assume* (6.52), (6.54),

$$(a/d)_L (d/a)_L > \left[(-b/a)_L (-c/d)_L\right]^{-1}, \tag{6.61}$$

and (1.2) *possesses a coexistence state, say* (λ, μ, u, v). *Then,*

$$\lambda \leqslant -(-b/a)_L (a/d)_L \mu, \qquad \mu \leqslant -(-c/d)_L (d/a)_L \lambda, \tag{6.62}$$

and

$$\begin{aligned}\int_0^T u &\leqslant \frac{-T(\lambda + (-b/a)_L(a/d)_L\mu)}{a_L[(-b/a)_L(-c/d)_L(a/d)_L(d/a)_L - 1]},\\ \int_0^T v &\leqslant \frac{-T(\mu + (-c/d)_L(d/a)_L\lambda)}{d_L[(-b/a)_L(-c/d)_L(a/d)_L(d/a)_L - 1]}.\end{aligned} \tag{6.63}$$

Therefore, for each $\lambda > 0$ *and* $\mu > 0$ *there exist*

$$\mu_1 = \mu_1(\lambda) \in [\mu_0, 0) \quad \textit{and} \quad \lambda_1 = \lambda_1(\mu) \in [\lambda_0, 0)$$

such that

$$P_\mu \mathfrak{C}^\lambda_\mu \in \{(-\infty, \mu_1], (-\infty, \mu_0)\} \quad \textit{and} \quad P_\lambda \mathfrak{C}^\mu_\lambda \in \{(-\infty, \lambda_1], (-\infty, \lambda_0)\}.$$

PROOF. Dividing by u the u-equation, by v the v-equation, and integrating in $[0, T]$ gives

$$\lambda = \frac{1}{T}\int_0^T (au + bv), \qquad \mu = \frac{1}{T}\int_0^T (dv + cu). \tag{6.64}$$

Thus,

$$\begin{aligned}\int_0^T (au) &= \lambda T - \int_0^T (bv) \geqslant \lambda T + (-b/a)_L \int_0^T (av)\\ &\geqslant \lambda T + (-b/a)_L(a/d)_L \int_0^T (dv)\\ &= T\lambda + (-b/a)_L(a/d)_L T\mu + (-b/a)_L(a/d)_L \int_0^T (-cu)\\ &\geqslant T\lambda + (-b/a)_L(a/d)_L T\mu\\ &\quad + (-b/a)_L(-c/d)_L(a/d)_L(d/a)_L \int_0^T (au)\end{aligned}$$

and, hence,

$$\bigl[1 - (-b/a)_L(-c/d)_L(a/d)_L(d/a)_L\bigr]\int_0^T (au) \geqslant T\bigl[\lambda + (-b/a)_L(a/d)_L\mu\bigr].$$

Similarly,

$$\bigl[1 - (-b/a)_L(-c/d)_L(a/d)_L(d/a)_L\bigr]\int_0^T (dv) \geqslant T\bigl[\mu + (-c/d)_L(d/a)_L\lambda\bigr].$$

On the other hand, thanks to (6.61), we have that

$$(-b/a)_L(-c/d)_L(a/d)_L(d/a)_L > 1,$$

and, hence, (6.62) holds true. Therefore,

$$\begin{aligned} a_L \int_0^T u &\leqslant \int_0^T (au) \leqslant -T\frac{\lambda + (-b/a)_L(a/d)_L\mu}{(-b/a)_L(-c/d)_L(a/d)_L(d/a)_L - 1}, \\ d_L \int_0^T v &\leqslant \int_0^T (dv) \leqslant -T\frac{\mu + (-c/d)_L(d/a)_L\lambda}{(-b/a)_L(-c/d)_L(a/d)_L(d/a)_L - 1}, \end{aligned} \tag{6.65}$$

and, consequently, (6.63) is as well true.

Now, fix $\lambda > 0$ and consider $\mathfrak{C}_\mu^\lambda$. Thanks to Theorem 6.6(a), $\mathfrak{C}_\mu^\lambda$ is unbounded in $\mathbb{R} \times \mathcal{C}_T \times \mathcal{C}_T$. Moreover, due to second estimate of (6.62),

$$P_\mu \mathfrak{C}_\mu^\lambda \cap [0, \infty) = \emptyset.$$

On the other hand, thanks to (6.63), u and v possess uniform a priori bounds in $\mathcal{C}_T$ on compact subsets of (λ, μ). Indeed, it is rather clear that (6.63) shows that u_L and v_L are uniformly bounded. Now, pick $t_u, t_v \in \mathbb{R}$ such that

$$u_L = u(t_u), \qquad v_L = v(t_v).$$

Then,

$$u(t) = \mathrm{e}^{\int_{t_u}^t (\lambda\ell - au - bv)} u(t_u), \qquad v(t) = \mathrm{e}^{\int_{t_v}^t (\mu m - dv - cu)} v(t_v),$$

must be uniformly bounded, as well. This concludes the proof. □

Even in the case when the model possesses a stable coexistence state, the solutions of (1.1) might blow up in finite time for sufficiently large initial data. In the case of high symbiosis, where according to Theorem 6.9 Problem (1.2) does not admit a coexistence state if $\lambda > 0$ and $\mu > 0$, all solutions of (1.1) will blow-up in finite time independently of the size of the initial populations. Actually, this is the reason why (1.2) cannot admit a coexistence state. We refrain of giving more details here in, though we send to the interested reader to [11] for further technical details concerning the elliptic counterpart of the model studied here in.

7. The competing species model ($b > 0$ and $c > 0$)

Undoubtedly, this is the case that has attracted more attention in the mathematical literature. Perhaps, because in a certainly pioneer chapter, P. de Mottoni and A. Schiaffino [29] showed that any solution of (1.1) converges in the large to a T-periodic component-wise non-negative solution of (1.2), which extraordinary facilitates the analysis of the dynamics of (1.1). Among the most important works related to this model one should include the most pioneering chapter of J.M. Cushing [7], where the average of the birth rates, λ and μ, were used by the first time as the main bifurcation parameters to show the existence of a continuum, not necessarily a curve, of coexistence states of (1.2) linking the two semi-trivial states of the model. Then, a huge industry grew from these pioneering chapters. Among the most important posterior works one should quote those of S. Ahmad [1], S. Ahmad and A.C. Lazer [2], C. Alvárez and A.C. Lazer [3], J.C. Eilbeck and J. López-Gómez [12], J.K. Hale and A. Somolinos [14], P. Hess and A.C. Lazer [15], J. López-Gómez [17], R. Ortega and A. Tineo [30], H. Smith [32,33], A. Tineo [34,35], and F. Zanolin [36], among many others that are omitted here; many of them authorized by the previous authors.

Rather naturally, in this section we will focus our attention into the results obtained in [17] and [12], where it was proved that the components $\mathfrak{C}^{\lambda}_{\mu}$ and $\mathfrak{C}^{\mu}_{\lambda}$ are real analytic curves consisting of coexistence states whose attractive character changes when a turning point is crossed. This theorem is a very sharp improvement of a previous result by R. Ortega and A. Tineo [30], were it was shown that either the model possess a segment of coexistence states, or it exhibits a finite number of coexistence states.

Although in the previous references some uniqueness results were given, the problem of the uniqueness remains, in its wide amplitude, entirely open, and it will be treated elsewhere.

7.1. *Periodic systems of quasi-cooperative type*

In this section we study the periodic linear system

$$\begin{cases} u' = \alpha u - \beta v, \\ v' = -\gamma u + \rho v, \end{cases} \tag{7.1}$$

where $\alpha, \beta, \gamma, \rho \in \mathcal{C}_T$ satisfy

$$\int_0^T \alpha < 0, \qquad \int_0^T \rho < 0, \qquad \beta > 0, \qquad \gamma > 0, \tag{7.2}$$

and its associated Cauchy problem

$$\begin{cases} u' = \alpha u - \beta v, \\ v' = -\gamma u + \rho v, \\ u(0) = u_0, \quad v(0) = v_0. \end{cases} \tag{7.3}$$

As an immediate consequence from Theorem 6.1, it follows the next result.

THEOREM 7.1. *Suppose* (7.1) *possesses a solution* $(u, v) \in \mathcal{C}^1_T \times \mathcal{C}^1_T \setminus \{(0, 0)\}$. *Then, either* $u \gg 0$ *and* $v \ll 0$, *or else* $u \ll 0$ *and* $v \gg 0$. *Therefore, all the coexistence states* *of* (1.2) *must be ordered, in the sense that for any pair of coexistence states,* $(u_1, v_1) \neq (u_2, v_2)$, *either* $u_1 \gg u_2$ *and* $v_1 \ll v_2$, *or* $u_1 \ll u_2$ *and* $v_1 \gg v_2$.

PROOF. The change of variable

$$(x, y) = (u, -v) \tag{7.4}$$

transforms (7.1) into

$$\begin{cases} x' = \alpha x + \beta y, \\ y' = \gamma x + \rho y, \end{cases} \tag{7.5}$$

which is of the same type as (6.1). Therefore, the result is a corollary of Theorem 6.1. □

Similarly, the following quasi-cooperative counterpart of Proposition 6.2 holds.

PROPOSITION 7.2. *Suppose* $(\bar{u}, \bar{v}) \in \mathcal{C}^1(\mathbb{R}_+) \times \mathcal{C}^1(\mathbb{R}_+)$, $\mathbb{R}_+ := [0, \infty)$, *satisfy*

$$\begin{cases} \bar{u}' \geqslant \alpha \bar{u} - \beta \bar{v}, \\ \bar{v}' \leqslant -\gamma \bar{u} + \rho \bar{v}, \\ \bar{u}(0) > 0, \quad \bar{v}(0) < 0. \end{cases} \tag{7.6}$$

Then, $\bar{u}(t) > 0$ *and* $\bar{v}(t) < 0$ *for each* $t \geqslant 0$.

If $u_0 - v_0 > 0$ *and* $u_0 v_0 = 0$, *then there exists* $t_0 > 0$ *such that the unique solution* (u, v) *of* (7.3) *satisfies* $u(t) > 0$ *and* $v(t) < 0$ *for each* $t \geqslant t_0$.

PROOF. The auxiliary pair

$$(\bar{x}, \bar{y}) := (\bar{u}, -\bar{v})$$

satisfies

$$\begin{cases} \bar{x}' \geqslant \alpha \bar{x} + \beta \bar{y}, \\ \bar{y}' \geqslant \gamma \bar{x} + \rho \bar{y}, \\ \bar{x}(0) > 0, \quad \bar{y}(0) > 0, \end{cases}$$

and, hence, thanks to Proposition 6.2, $\bar{x}(t) > 0$ and $\bar{y}(t) > 0$ for each $t \geqslant 0$, which concludes the proof of the first claim.

Now, suppose $u_0 - v_0 > 0$ and $u_0 v_0 = 0$, and let $(u(t), v(t))$ denote the unique solution of (7.3). Then,

$$(x, y) := (u, -v)$$

satisfies

$$\begin{cases} x' = \alpha x + \beta y, \\ y' = \gamma x + \rho y, \\ x(0) = u_0, \quad y(0) = -v_0, \end{cases}$$

and

$$x(0) + y(0) = u_0 - v_0 > 0, \qquad x(0)y(0) = 0.$$

Thus, it follows from Proposition 6.2 that there exists $t_0 > 0$ such that $x(t) > 0$ and $y(t) > 0$ for each $t \geqslant t_0$. Therefore, $u(t) > 0$ and $v(t) < 0$ for each $t \geqslant t_0$, which concludes the proof. ☐

Also, the following counterpart of Theorem 6.3 holds. Subsequently, we shall denote by $\Phi(T)$ the Poincaré map of (7.1).

THEOREM 7.3. *The characteristic multipliers of* (7.1), ν_1 *and* ν_2, *are real and distinct, and satisfy* $0 < \nu_1\nu_2 < 1$. *Moreover, if we order them so that* $0 < \nu_1 < \nu_2$, *then,* $0 < \nu_1 < 1$,

$$N\big[\Phi(T) - \nu_1 I\big] = \operatorname{span}\big[(x_0, y_0)\big] \quad \textit{with } x_0 > 0 \textit{ and } y_0 > 0,$$

and

$$N\big[\Phi(T) - \nu_2 I\big] = \operatorname{span}\big[(x_0, y_0)\big] \quad \textit{with } x_0 > 0 \textit{ and } y_0 < 0.$$

In particular, (7.1) *is asymptotically stable if* $\nu_2 < 1$, *neutrally stable if* $\nu_2 = 1$, *and unstable if* $\nu_2 > 1$. *Furthermore, the value*

$$\lambda_0 := -\frac{1}{T}\operatorname{Log}\nu_2 \tag{7.7}$$

provides us with the unique value of $\lambda \in \mathbb{R}$ *for which the eigenvalue problem*

$$\begin{cases} u' = \alpha u - \beta v + \lambda u, \\ v' = -\gamma u + \rho v + \lambda v \end{cases} \tag{7.8}$$

admits a solution $(u, v) \in \mathcal{C}^1_T \times \mathcal{C}^1_T$ *such that* $u \gg 0$ *and* $v \ll 0$.

PROOF. As the change of variable (7.4) transforms (7.1) into (7.5), if

$$U(T) = \begin{pmatrix} u_{11} & u_{12} \\ u_{21} & u_{22} \end{pmatrix}$$

denotes the Poincaré map of (7.5), necessarily

$$\Phi(T)=\begin{pmatrix} u_{11} & -u_{12} \\ -u_{21} & u_{22} \end{pmatrix}. \tag{7.9}$$

Indeed, if we denote by $(u(t), v(t))$ the unique solution of (7.3) and $(x(t), y(t))$ stands for the unique solution of (7.5) satisfying $(x(0), y(0)) = (u_0, -v_0)$, then

$$\begin{pmatrix} u(T) \\ v(T) \end{pmatrix} = \begin{pmatrix} x(T) \\ -y(T) \end{pmatrix} = \begin{pmatrix} u_{11} & -u_{12} \\ -u_{21} & u_{22} \end{pmatrix} \begin{pmatrix} x(0) \\ -y(0) \end{pmatrix} = \Phi(T) \begin{pmatrix} u_0 \\ v_0 \end{pmatrix}.$$

Clearly, the eigenvalues of $U(T)$ and $\Phi(T)$ are the same. Moreover, thanks to Theorem 6.3,

$$N\big[U(T)-\nu_1 I\big] = \operatorname{span}\big[(\tilde{x}_0, \tilde{y}_0)\big] \quad \text{with } \tilde{x}_0 < 0 \text{ and } \tilde{y}_0 > 0,$$
$$N\big[U(T)-\nu_2 I\big] = \operatorname{span}\big[(\tilde{x}_0, \tilde{y}_0)\big] \quad \text{with } \tilde{x}_0 > 0 \text{ and } \tilde{y}_0 > 0,$$

and a direct calculation shows that, for each $j \in \{1, 2\}$, (x, y) is an eigenvector of $U(T)$ associated to the eigenvalue ν_j if, and only if, $(x, -y)$ is an eigenvector of $\Phi(T)$ associated to ν_j. Therefore,

$$N\big[\Phi(T)-\nu_1 I\big] = \operatorname{span}\big[(x_0, y_0)\big] \quad \text{with } x_0 > 0 \text{ and } y_0 > 0,$$

and

$$N\big[\Phi(T)-\nu_2 I\big] = \operatorname{span}\big[(x_0, y_0)\big] \quad \text{with } x_0 > 0 \text{ and } y_0 < 0,$$

which concludes the proof of the first block of statements.

Finally, note that the change of variable (7.4) transforms (7.8) into the equivalent system

$$\begin{cases} x' = \alpha x + \beta y + \lambda x, \\ y' = \gamma x + \rho y + \lambda y, \end{cases}$$

for which the last assertion of Theorem 6.3 is valid. This concludes the proof. □

Finally, by performing the change of variable (7.4), it is easy to see that the following counterpart of Theorem 6.4 is satisfied.

THEOREM 7.4. *The following properties are satisfied*:

(a) *System* (7.1) *is stable* ($\nu_2 < 1$) *if, and only if, there exists* $(\bar{u}, \bar{v}) \in \mathcal{C}^1_T \times \mathcal{C}^1_T$ *with* $\bar{u} \gg 0$ *and* $\bar{v} \ll 0$ *such that*

$$\begin{cases} \bar{u}' \geqslant \alpha \bar{u} - \beta \bar{v}, \\ \bar{v}' \leqslant -\gamma \bar{u} + \rho \bar{v}, \end{cases} \tag{7.10}$$

with some of these inequalities strict.

(b) *System* (6.1) *is unstable* ($\nu_2 > 1$) *if, and only if, there exits* $(\underline{u}, \underline{v}) \in \mathcal{C}^1_T \times \mathcal{C}^1_T$ *with* $\underline{u} \gg 0$ *and* $\underline{v} \ll 0$ *such that*

$$\begin{cases} \underline{u}' \leqslant \alpha \underline{u} - \beta \underline{v}, \\ \underline{v}' \geqslant -\gamma \underline{u} + \rho \underline{v}, \end{cases} \tag{7.11}$$

with some of these inequalities strict.

7.2. *Structure of the components* $\mathfrak{C}^\lambda_\mu$ *and* $\mathfrak{C}^\mu_\lambda$

As in Section 6.2, the coexistence states of (1.2) will be regarded as zeroes of the operator $\mathfrak{F} : \mathbb{R}^2 \times \mathcal{C}_T \times \mathcal{C}_T \to \mathcal{C}_T \times \mathcal{C}_T$ defined by (6.23), where $M > 0$ is fixed. The following counterpart of Proposition 6.5 is satisfied.

PROPOSITION 7.5. *Suppose* $(u_0, v_0) \in \mathcal{C}_T \times \mathcal{C}_T$ *satisfies* $u_0 \gg 0$, $v_0 \gg 0$, *and*

$$\mathfrak{F}(\lambda, \mu, u_0, v_0) = 0.$$

Then, each of the operators

$$D_{(\lambda,u,v)}\mathfrak{F}(\lambda, \mu, u_0, v_0) : \mathbb{R} \times \mathcal{C}_T \times \mathcal{C}_T \to \mathcal{C}_T \times \mathcal{C}_T$$

and

$$D_{(\mu,u,v)}\mathfrak{F}(\lambda, \mu, u_0, v_0) : \mathbb{R} \times \mathcal{C}_T \times \mathcal{C}_T \to \mathcal{C}_T \times \mathcal{C}_T$$

is surjective. In other words, $(0, 0)$ *is a regular value of* $\mathfrak{F}$ *with respect to* $\mathbb{R}^2 \times \operatorname{Int} P \times \operatorname{Int} P$.

PROOF. As in the proof of Proposition 6.5, differentiating gives (6.24), (6.25) and (6.26). Similarly, $D_{(\lambda,u,v)}\mathfrak{F}(\lambda, \mu, u_0, v_0)$ and $D_{(\mu,u,v)}\mathfrak{F}(\lambda, \mu, u_0, v_0)$ are surjective if (λ, μ, u_0, v_0) is non-degenerate. So, suppose (λ, μ, u_0, v_0) is degenerate. Then, since $D_{(u,v)}\mathfrak{F}(\lambda, \mu, u_0, v_0)$ is a compact perturbation of the identity,

$$N := \dim N\big[D_{(u,v)}\mathfrak{F}(\lambda, \mu, u_0, v_0)\big] = \operatorname{codim} R\left[D_{(u,v)}\mathfrak{F}(\lambda, \mu, u_0, v_0)\right] \geqslant 1,$$

and $N[D_{(u,v)}\mathfrak{F}(\lambda, \mu, u_0, v_0)]$ is the set of T-periodic solutions (u, v) of the linear system

$$\begin{cases} u' = \alpha_0 u - b u_0 v, \\ v' = -c v_0 u + \beta_0 v. \end{cases} \tag{7.12}$$

Since $b > 0$ and $c > 0$, we have that

$$-b u_0 < 0 \quad \text{and} \quad -c v_0 < 0.$$

Moreover, since (λ,μ,u_0,v_0) is a coexistence state of (1.2),

$$\int_0^T \alpha_0 = -\int_0^T a(t)u_0(t)\,\mathrm{d}t < 0 \quad \text{and} \quad \int_0^T \beta_0 = -\int_0^T d(t)v_0(t)\,\mathrm{d}t < 0.$$

Therefore, (7.12) fits into the abstract setting of Section 7.1. Thus, thanks to Theorem 7.3, the biggest multiplier of (7.12), denoted by ν_2, equals one and any T-periodic solution of (7.12) must be a multiple of a fixed T-periodic solution (φ,ψ) such that $\varphi \gg 0$ and $\psi \ll 0$. In particular, $N = 1$. Now, due to (6.25) and (6.26), to conclude the proof it suffices to prove (6.29). On the contrary, suppose that, e.g.,

$$-\mathfrak{R}_M(\ell u_0, 0) \in R\big[D_{(u,v)}\mathfrak{F}(\lambda,\mu,u_0,v_0)\big].$$

Then, the system

$$\begin{cases} u' = \alpha_0 u - b u_0 v + \ell u_0, \\ v' = -c v_0 u + \beta_0 v, \end{cases} \tag{7.13}$$

possesses a T-periodic solution (u,v). Actually, for each $R > 0$, the pair

$$(u_R, v_R) := (u + R\varphi, v + R\psi)$$

provides us with a T-periodic solution of (7.13) such that, for sufficiently large $R > 0$,

$$u_R \gg 0 \quad \text{and} \quad v_R \ll 0.$$

Moreover, it follows from $\ell u_0 > 0$ that

$$\begin{cases} u_R' > \alpha_0 u_R - b u_0 v_R, \\ v_R' = -c v_0 u_R + \beta_0 v_R, \end{cases}$$

and, therefore, thanks to Theorem 7.4(a), $\nu_2 < 1$, which is a contradiction, since $\nu_2 = 1$. Similarly, the second relation of (6.29) holds. This concludes the proof. □

The following result ascertains the global structure of the coexistence states of (1.2) for the competing species model. To reduce the complexity of the number of cases to be considered in our analysis we shall throughout assume that conditions (4.10) are satisfied, though most of the results are still valid in the absence of (4.10)—such restrictions are exclusively needed in order to get some non-existence results entailing the relative compactness of the components $\mathfrak{C}_\mu^\lambda$ and $\mathfrak{C}_\lambda^\mu$.

THEOREM 7.6. *Assume* $b > 0$, $c > 0$, *and* (1.2) *exhibits a coexistence state, say* (λ,μ,u_0,v_0). *Then,* $\lambda > 0$, $\mu > 0$, *and*

$$u_0 \ll \theta_{[\lambda\ell,a]}, \qquad v_0 \ll \theta_{[\mu m,d]}. \tag{7.14}$$

Moreover, the following properties are satisfied:

(a) *For each* $\lambda > 0$ *there exists* $\mu_1(\lambda) > 0$ *such that* (1.2) *does not admit a coexistence state if* $\mu \geqslant \mu_1(\lambda)$. *Moreover, the component of coexistence states* $\mathfrak{C}_\mu^\lambda$ *constructed in Theorem* 5.4 *is bounded in* $\mathbb{R} \times \mathcal{C}_T \times \mathcal{C}_T$ *and it consists of a real analytic curve. More precisely, there exits a real analytic map* $(\mu, u, v) : [0, 1] \to \mathbb{R} \times \operatorname{Int} P \times \operatorname{Int} P$ *such that*

$$\big(\mu(0), u(0), v(0)\big) = (\mu_0, \theta_{[\lambda\ell,a]}, 0),$$
$$\big(\mu(1), u(1), v(1)\big) = (\mu_*, 0, \theta_{[\mu_* m,d]}),$$

and

$$\mathfrak{C}_\mu^\lambda = \big\{\big(\mu(s), u(s), v(s)\big) \colon\ s \in (0, 1)\big\},$$

where $\mu_* > 0$ *is the unique value of* μ *satisfying* (5.40).

(b) *For each* $\mu > 0$ *there exists* $\lambda_1(\mu) > 0$ *such that* (1.2) *does not admit a coexistence state if* $\lambda \geqslant \lambda_1(\mu)$. *Moreover, the component of coexistence states* $\mathfrak{C}_\lambda^\mu$ *constructed in Theorem* 5.5 *is bounded in* $\mathbb{R} \times \mathcal{C}_T \times \mathcal{C}_T$ *and it consists of a real analytic curve. More precisely, there exists a real analytic map* $(\lambda, u, v) : [0, 1] \to \mathbb{R} \times \operatorname{Int} P \times \operatorname{Int} P$ *such that*

$$\big(\lambda(0), u(0), v(0)\big) = (\lambda_0, 0, \theta_{[\mu m,d]}),$$
$$\big(\lambda(1), u(1), v(1)\big) = (\lambda_*, \theta_{[\lambda_*\ell,a]}, 0),$$

and

$$\mathfrak{C}_\lambda^\mu = \big\{(\lambda(s), u(s), v(s)\big) \colon\ s \in (0, 1)\big\},$$

where $\lambda_* > 0$ *is the unique value of* λ *satisfying* (5.46).

(c) *The set of coexistence states of* (1.2) $(\lambda, \mu, u, v) \in \mathbb{R}^2 \times \operatorname{Int} P \times \operatorname{Int} P$ *such that, for some* $\mu \in \mathbb{R}$, $(\mu, u, v) \in \mathfrak{C}_\mu^\lambda$, *or, for some* $\lambda \in \mathbb{R}$, $(\lambda, u, v) \in \mathfrak{C}_\lambda^\mu$, *is a real analytic surface linking the surfaces of semi-trivial states*

$$\big\{(\lambda, \mu, \theta_{[\lambda\ell,a]}, 0) : \lambda > 0,\ \mu \in \mathbb{R}\big\}$$

and

$$\big\{(\lambda, \mu, 0, \theta_{[\mu m,d]}) \colon\ \lambda \in \mathbb{R},\ \mu > 0\big\}$$

along their respective curves of neutral stability

$$\mu = \frac{1}{T}\int_0^T c(t)\theta_{[\lambda\ell,a]}(t)\,\mathrm{d}t \quad \textit{and} \quad \lambda = \frac{1}{T}\int_0^T b(t)\theta_{[\mu m,d]}(t)\,\mathrm{d}t.$$

Therefore, (1.2) *possesses a coexistence state if both semi-trivial states are, simultaneously, linearly unstable, or linearly stable.*

PROOF. The fact that the components $\mathfrak{C}_\mu^\lambda$ and $\mathfrak{C}_\lambda^\mu$ are real analytic curves follows from Proposition 7.5 adapting the argument of the proof of Theorem 6.6. Now, we shall show that both components are bounded. The remaining assertions of the theorem follow straight ahead from Theorems 5.4 and 5.5.

Suppose (λ, μ, u_0, v_0) is a coexistence state of (1.2). Then, dividing by u_0 the u-equation, by v_0 the v-equation, and integrating in $[0, T]$ gives

$$\lambda = \frac{1}{T}\int_0^T (au_0 + bv_0) > 0 \quad \text{and} \quad \mu = \frac{1}{T}\int_0^T (dv_0 + cu_0) > 0.$$

Thus, $\lambda > 0$ and $\mu > 0$ are necessary for the existence of a coexistence state. So, throughout the remaining of the proof we will assume that $\lambda > 0$ and $\mu > 0$.

Fix $\lambda > 0$. Then, $u_0 \gg 0$ is a positive strict subsolution of the problem

$$u' = \lambda\ell - au^2, \quad u \in \mathcal{C}_T^1,$$

since $bu_0v_0 > 0$, and, hence, thanks to Proposition 2.6, $u_0 \ll \theta_{[\lambda\ell,a]}$. Similarly, $v_0 \ll \theta_{[\mu m,d]}$. Thus,

$$v_0 = \mu m v_0 - dv_0^2 - cu_0v_0 > (\mu m - c\theta_{[\lambda\ell,a]})v_0 - dv_0^2.$$

Hence, if

$$\mu > \frac{1}{T}\int_0^T c(t)\theta_{[\lambda\ell,a]}(t)\,\mathrm{d}t,$$

then, thanks again to Proposition 2.6, we have that

$$v_0 \gg \theta_{[\mu m - c\theta_{[\lambda\ell,a]},d]} := \Theta_\mu,$$

and, so,

$$u_0 < (\lambda\ell - b\Theta_\mu)u_0 - au_0^2.$$

Consequently, dividing by u_0 and integrating in $[0, T]$ gives

$$\lambda > \frac{1}{T}\int_0^T b(t)\Theta_\mu(t)\,\mathrm{d}t. \tag{7.15}$$

To show the existence of $\mu_1(\lambda)$ such that (1.2) cannot admit a coexistence state if $\mu \geqslant \mu_1$ it suffices to show that (7.15) cannot be satisfied for sufficiently large μ. To show this, note that the function Ψ_μ defined through $\Theta_\mu := \mu\Psi_\mu$ satisfies

$$\frac{1}{\mu}\Psi_\mu' = \left(m - \frac{c\theta_{[\lambda\ell,a]}}{\mu}\right)\Psi_\mu - \mathrm{d}\Psi_\mu^2.$$

Adapting the argument of the proof of (2.20) it is apparent that $\lim_{\mu\uparrow\infty}\Psi_\mu = \frac{m}{d}$ uniformly in $\mathbb{R}$, since $\lim_{\mu\uparrow\infty}\frac{c\theta_{[\lambda\ell,a]}}{\mu} = 0$. Therefore,

$$\lim_{\mu\uparrow\infty}\Theta_\mu = \infty$$

uniformly in $[0,T]$, and, consequently, (7.15) fails to be true for sufficiently large μ. By symmetry, for any $\mu > 0$ there exists $\lambda_1(\mu) > 0$ such that (1.2) does not admit a coexistence state if $\lambda \geqslant \lambda_1(\mu)$.

The previous bounds show that $\mathfrak{C}^\lambda_\mu$ and $\mathfrak{C}^\mu_\lambda$ must be bounded for each $\lambda > 0$ and $\mu > 0$. The remaining assertions of the theorem follow readily from Theorems 5.4, 5.5 and 5.6. □

For the autonomous counterpart of (1.2) with $bc = 1$, is easy to check that, for any $\lambda > 0$, the curve

$$\big(\mu(s), u(s), v(s)\big) = (c\lambda, \lambda - bs, s), \quad 0 \leqslant s \leqslant \frac{\lambda}{b},$$

provides us with the component $\mathfrak{C}^\lambda_\mu$ bifurcating from the semi-trivial solution $(\lambda, 0)$ at $\mu = c\lambda$. As this simple example shows, condition $\dot{\mu} = 0$ cannot be avoided in general, unless some additional assumptions are imposed; e.g., that the semi-trivial states cannot be simultaneously neutrally stable.

As in the symbiotic model, fixing λ, or μ, and due to Proposition 7.5, any coexistence state of (1.2), say (λ, μ, u_0, v_0), must lay into a real analytic curve of coexistence states of (1.2). Fix, e.g., λ and let Γ denote the trajectory of the μ–curve of coexistence states containing (λ, μ, u_0, v_0). As a consequence from the existence of uniform a priori bounds in $\mathcal{C}_T$ for the coexistence states of (1.2) (cf. Theorem 7.6), Γ must be bounded. If $\Gamma \cap \mathfrak{C}^\lambda_\mu \neq \emptyset$, then $\Gamma = \mathfrak{C}^\lambda_\mu$. Thus, if $\Gamma \neq \mathfrak{C}^\lambda_\mu$, necessarily $\Gamma \cap \mathfrak{C}^\lambda_\mu = \emptyset$, and, consequently, Γ must be an isolated component with respect of the surfaces of semi-trivial positive solutions of (1.2). Suppose such a component exists. Then, by varying an additional parameter of the model, e.g., the amplitude of b, or c, it is possible to show that when b, or c are sufficiently small, then (1.2) possesses a unique coexistence state, necessarily belonging to $\mathfrak{C}^\lambda_\mu$. Therefore, at some intermediate value of the *unfolding parameter*, the isolated component Γ must reduce to a single point. Thanks to Proposition 7.5 this is impossible. Therefore, the only coexistence states of (1.2) are those contained in the components $\mathfrak{C}^\lambda_\mu$. The technical details of this analysis will appear elsewhere.

As an easy consequence from Theorem 7.6, except in the case when both semi-trivial states are neutrally stable, (1.2) possesses, at most, a finite number of coexistence states and, according to Theorem 7.1, all of them must be ordered, which provides us with the main result of R. Ortega and A. Tineo [30].

In the case when both semi-trivial states are neutrally stable, either there is an analytic curve of coexistence states linking both states, or the model possesses a finite number of coexistence states; its cardinal depending on the values of the several parameter functions involved in the setting of the model.

7.3. *Stability of the coexistence states along $\mathfrak{C}^{\lambda}_{\mu}$ and $\mathfrak{C}^{\mu}_{\lambda}$*

Fix $\lambda > 0$ and let $(\mu(s), u(s), v(s))$, $s \geqslant 0$, be the real analytic map constructed in Theorem 7.6, where $s \in (0, L)$ is assumed to be the length of arc of curve. Subsequently, we shall denote $\cdot := \frac{\mathrm{d}}{\mathrm{d}s}$. Repeating the argument of Section 6.3, we have (6.31) and (6.32). Moreover, since

$$\big(\mu(0), u(0), v(0)\big) = (\mu_0, \theta_{[\lambda\ell,a]}, 0),$$

it follows from Theorem 5.6 that

$$q_s := \dot{v}(s) = \varphi_v + \mathrm{O}(s) = \mathrm{e}^{\int_0^{\cdot}(\mu_0 m - c\theta_{[\lambda\ell,a]})} + \mathrm{O}(s) \gg 0, \quad s \downarrow 0. \tag{7.16}$$

Similarly, setting

$$(p_s, q_s) := \big(\dot{u}(s), \dot{v}(s)\big), \quad s > 0,$$

(6.31) can be rewritten in the form

$$\begin{cases} (p_s)' = \big[\lambda\ell - 2au(s) - bv(s)\big]p_s - bu(s)q_s, \\ (q_s)' = -cv(s)p_s + \big[\mu(s)m - 2dv(s) - cu(s)\big]q_s + \dot{\mu}(s)mv(s). \end{cases} \tag{7.17}$$

In the competing species model, we have that $-bu(s) < 0$, $-cv(s) < 0$, (6.35) and (6.36). Thus, (7.17) fits within the general setting of Section 7.1. In particular, thanks to Proposition 2.1, we find from the first equation of (7.17) that, for each sufficiently small $s > 0$,

$$p_s = \mathfrak{R}_{-[\lambda\ell - 2au(s) - bv(s)]}\big(-bu(s)q_s\big) \ll 0.$$

Therefore, there exists $\varepsilon > 0$ such that

$$p_s \ll 0 \quad \text{and} \quad q_s \gg 0 \quad \text{for each } s \in [0, \varepsilon]. \tag{7.18}$$

Suppose $\mu(s) = \mu_0$ for each $s \in [0, L]$. Then, (7.17) becomes into (6.38) and, due to (6.32), $(p_s, q_s) \neq (0, 0)$. Thus, thanks to Theorem 7.1, for each $s \in [0, L]$, either $p_s \gg 0$ and $q_s \ll 0$, or $p_s \ll 0$ and $q_s \gg 0$. Thanks to (7.18), necessarily

$$p_s \ll 0 \quad \text{and} \quad q_s \gg 0 \quad \text{for each } s \in [0, L]. \tag{7.19}$$

Indeed, since $s \to (p_s, q_s)$ is analytic, if (7.19) is not satisfied, then, due to (6.37), there is some value of s, say $\tilde{s} \in (0, L]$ where $p_{\tilde{s}} < 0$, $q_{\tilde{s}} > 0$, and, e.g., $p_{\tilde{s}} \ll 0$ fails. Due to Theorem 7.1, this implies $p_{\tilde{s}} \ll 0$ and $q_{\tilde{s}} \gg 0$, which is a contradiction. Thus, (7.19) holds true. Consequently, thanks to Theorem 7.3, the principal characteristic multiplier of $(\mu(s), u(s), v(s))$, $\nu_2(s)$, equals 1 for each $s \in [0, L]$. Therefore, if $\dot{\mu} = 0$, then $\dot{\nu}_2 = 0$ and, hence, all the coexistence states of $\mathfrak{C}^{\lambda}_{\mu}$ are neutrally stable. When $\dot{\mu} \neq 0$, the following result is satisfied.

THEOREM 7.7. *Suppose $\dot\mu \neq 0$ in $[0, L]$. Then, the set*

$$\mathcal{S} := \{s \in (0, L)\colon\ \dot\mu(s) = 0\} \tag{7.20}$$

is finite (possibly empty), each $s \in \mathcal{S}$ is a zero of finite order of $\dot\mu$, and

$$\mathcal{S} = \{s \in (0, L)\colon\ \nu_2(s) = 1\}. \tag{7.21}$$

Moreover,

$$\dot\mu(s)\bigl(1 - \nu_2(s)\bigr) > 0, \quad s \in (0, L) \setminus \mathcal{S}, \tag{7.22}$$

and

$$p_s \ll 0 \quad \textit{and} \quad q_s \gg 0 \quad \textit{whenever} \quad \dot\mu(s) \geqslant 0. \tag{7.23}$$

PROOF. The fact that $\mathcal{S}$ is, at most, finite and that each $s \in \mathcal{S}$ has finite order—as a zero of $\dot\mu$—are consequences from the fact that $\dot\mu$ is real analytic. Now, we shall prove (7.21). Pick $s \in \mathcal{S}$. Then, (p_s, q_s) satisfies (6.38) and, due to (6.32), $(p_s, q_s) \neq (0, 0)$. Thus, thanks to Theorem 7.1, $p_s \ll 0$ and $q_s \gg 0$, or $p_s \gg 0$ and $q_s \ll 0$. In any of these cases, we find from Theorem 7.3 that $\lambda = 0$ is the *principal characteristic exponent* of $(\mu(s), u(s), v(s))$ and, hence, $\nu_2(s) = 1$. To prove the converse inclusion, let $s \in (0, L)$ such that $\nu_2(s) = 1$. Then, thanks to Theorem 7.3, there exists a T-periodic pair (P, Q) with $P \gg 0$ and $Q \ll 0$ such that

$$\begin{cases} P' = [\lambda\ell - 2au(s) - bv(s)]P - bu(s)Q, \\ Q' = -cv(s)P + [\mu(s)m - 2dv(s) - cu(s)]P. \end{cases} \tag{7.24}$$

Now, choose a sufficiently small $\varepsilon > 0$ so that the auxiliary pair

$$(U, V) := (P - \varepsilon p_s, Q - \varepsilon q_s),$$

satisfy $U \gg 0$ and $V \ll 0$. Thanks to (7.17) and (7.24) we have that

$$\begin{cases} U' = [\lambda\ell - 2au(s) - bv(s)]U - bu(s)V, \\ V' = -cv(s)U + [\mu(s)m - 2dv(s) - cu(s)]V - \varepsilon\dot\mu(s)mv(s). \end{cases}$$

Assume $\dot\mu(s) > 0$. Then, since $\varepsilon mv(s) > 0$, the pair (U, V) satisfies

$$\begin{cases} U' = [\lambda\ell - 2au(s) - bv(s)]U - bu(s)V, \\ V' < -cv(s)U + [\mu(s)m - 2dv(s) - cu(s)]V, \end{cases}$$

and, hence, thanks to Theorem 7.4(a), $\nu_2(s) < 1$, which is a contradiction. Assume $\dot{\mu}(s) < 0$. Then, (U, V) satisfies

$$\begin{cases} U' = \big[\lambda\ell - 2au(s) - bv(s)\big]U - bu(s)V, \\ V' > -cv(s)U + \big[\mu(s)m - 2dv(s) - cu(s)\big]V, \end{cases}$$

and, due to Theorem 7.4(b), $\nu_2(s) > 1$, which is a contradiction again. Consequently, $\dot{\mu}(s) = 0$ and, therefore, (7.21) holds true.

Now, pick $\tilde{s} \in \mathcal{S}$. Thanks to (6.32), it follows from Theorem 7.1 that some of the following alternatives occurs:

1. $p_{\tilde{s}} \gg 0$ and $q_{\tilde{s}} \ll 0$.
2. $p_{\tilde{s}} \ll 0$ and $q_{\tilde{s}} \gg 0$.

Assume alternative 1 occurs. As $\tilde{s}$ is an isolated zero of $\dot{\mu}(s)$, there exists $\varepsilon > 0$ such that $p_s = \dot{u}(s) \gg 0$ and $q_s = \dot{v}(s) \ll 0$ for each $s \in (\tilde{s} - \varepsilon, \tilde{s} + \varepsilon)$, and

$$\dot{\mu}^{-1}(0) \cap (\tilde{s} - \varepsilon, \tilde{s} + \varepsilon) \cap (0, L) = \{\tilde{s}\}.$$

Thus, for each

$$s \in J := (0, L) \cap \big[(\tilde{s} - \varepsilon, \tilde{s} + \varepsilon) \setminus \{\tilde{s}\}\big],$$

either $\dot{\mu}(s) > 0$, or $\dot{\mu}(s) < 0$. Suppose $\dot{\mu}(s) > 0$. Then,

$$\begin{cases} (p_s)' = \big[\lambda\ell - 2au(s) - bv(s)\big]p_s - bu(s)q_s, \\ (q_s)' > -cv(s)p_s + \big[\mu(s)m - 2dv(s) - cu(s)\big]q_s, \end{cases} \tag{7.25}$$

and it follows from Theorem 7.4(b) that $\nu_2(s) > 1$. Hence, $\dot{\mu}(s)(1 - \nu_2(s)) < 0$. Now, suppose $\dot{\mu}(s) < 0$. Then,

$$\begin{cases} (p_s)' = \big[\lambda\ell - 2au(s) - bv(s)\big]p_s - bu(s)q_s, \\ (q_s)' < -cv(s)p_s + \big[\mu(s)m - 2dv(s) - cu(s)\big]q_s, \end{cases} \tag{7.26}$$

and it follows from Theorem 7.4(a) that $\nu_2(s) < 1$. Hence, $\dot{\mu}(s)(1 - \nu_2(s)) < 0$. Therefore, the following condition is satisfied

$$\dot{\mu}(s)\big(1 - \nu_2(s)\big) < 0, \quad s \in (0, L) \cap \big[(\tilde{s} - \varepsilon, \tilde{s} + \varepsilon) \setminus \{\tilde{s}\}\big], \tag{7.27}$$

for each $\tilde{s} \in \mathcal{S}$ satisfying alternative 1.

Now, suppose $\tilde{s} \in \mathcal{S}$ satisfies alternative 2. As $\tilde{s}$ is an isolated zero of $\dot{\mu}(s)$, there exists $\varepsilon > 0$ such that $p_s = \dot{u}(s) \ll 0$ and $q_s = \dot{v}(s) \gg 0$ for each $s \in (\tilde{s} - \varepsilon, \tilde{s} + \varepsilon)$, and

$$\dot{\mu}^{-1}(0) \cap (\tilde{s} - \varepsilon, \tilde{s} + \varepsilon) \cap (0, L) = \{\tilde{s}\}.$$

Thus, for each

$$s \in J := (0, L) \cap \big[(\tilde{s} - \varepsilon, \tilde{s} + \varepsilon) \setminus \{\tilde{s}\}\big],$$

either $\dot{\mu}(s) > 0$, or $\dot{\mu}(s) < 0$. Suppose $\dot{\mu}(s) > 0$. Then,

$$\begin{cases} (-p_s)' = \big[\lambda\ell - 2au(s) - bv(s)\big](-p_s) - bu(s)(-q_s), \\ (-q_s)' < -cv(s)(-p_s) + \big[\mu(s)m - 2dv(s) - cu(s)\big](-q_s), \end{cases} \tag{7.28}$$

with $-p_s \gg 0$ and $-q_s \ll 0$, and, hence, due to Theorem 7.4(a), $\nu_2(s) < 1$. Thus, $\dot{\mu}(s)(1 - \nu_2(s)) > 0$. Similarly, if $\dot{\mu}(s) < 0$, then, due to Theorem 7.4(b), $\nu_2(s) < 1$. Therefore, condition (7.22) is satisfied for each $\tilde{s} \in \mathcal{S}$ satisfying alternative 2.

Now, suppose

$$\mathcal{S} = \{s_n \colon 1 \leqslant n \leqslant N\}, \quad 0 < s_n < s_{n+1},\ 1 \leqslant n \leqslant N - 1;$$

the subsequent argument is easily adapted to cover the case when $\mathcal{S}$ is empty. Thanks to (7.19), for sufficiently small $s > 0$, $p_s \ll 0$ and $q_s \gg 0$. Moreover, either $\dot{\mu}(s) > 0$ for each $s \in (0, s_1)$, or $\dot{\mu}(s) < 0$ for each $s \in (0, s_1)$.

Suppose $\dot{\mu}(s) > 0$ for each $s \in (0, s_1)$. Then, for sufficiently small $s > 0$, $(-p_s, -q_s)$ satisfies (7.28) and, hence, thanks to Theorem 7.4(a), $\nu_2(s) < 1$. Actually, this is the inter-exchange stability principle between the semi-trivial state $(\mu, \theta_{[\lambda\ell,a]}, 0)$ and the bifurcating coexistence state $(\mu(s), u(s), v(s))$ as μ crosses the bifurcation value μ_0. Thanks to (7.21), necessarily $\nu_2(s) < 1$ for each $s \in (0, s_1)$ and, therefore,

$$\dot{\mu}(s)\big(1 - \nu_2(s)\big) > 0, \quad s \in (0, s_1). \tag{7.29}$$

Necessarily $p_{s_1} \ll 0$ and $q_{s_1} \gg 0$. Indeed, if $p_{s_1} \gg 0$ and $q_{s_1} \ll 0$, then (7.27) holds, which contradicts (7.29). Therefore,

$$\dot{\mu}(s)\big(1 - \nu_2(s)\big) > 0, \quad s \in (0, s_2) \setminus \{s_2\}. \tag{7.30}$$

Reiterating this argument, (7.22) holds true.

Now, suppose $\dot{\mu}(s) < 0$ for each $s \in (0, s_1)$. Then, $(-p_s, -q_s)$ satisfies

$$\begin{cases} (-p_s)' = \big[\lambda\ell - 2au(s) - bv(s)\big](-p_s) - bu(s)(-q_s), \\ (-q_s)' > -cv(s)(-p_s) + \big[\mu(s)m - 2dv(s) - cu(s)\big](-q_s), \end{cases} \tag{7.31}$$

and, hence, thanks to Theorem 7.4(b), $\nu_2(s) > 1$. As in the previous case, this provides us with the inter-exchange stability principle between the semi-trivial state $(\mu, \theta_{[\lambda\ell,a]}, 0)$ and the bifurcating coexistence state $(\mu(s), u(s), v(s))$. Thanks to (7.21), $\nu_2(s) > 1$ for each $s \in (0, s_1)$ and, therefore, (7.22) is as well satisfied. Arguing as above, the proof of (7.22) is concluded.

Note that, as a result from the previous analysis, we have that

$$p_{\tilde{s}} \ll 0 \quad \text{and} \quad q_{\tilde{s}} \gg 0 \quad \text{for each } \tilde{s} \in \mathcal{S} \cup \{0\}. \tag{7.32}$$

Finally, let $s_1^*, s_2^* \in \mathcal{S} \cup \{0\}$ such that

$$\dot{\mu}(s) > 0, \quad s \in \left(s_1^*, s_2^*\right).$$

Thanks to (7.32), $p_s \ll 0$ and $q_s \gg 0$ for each $s > s_1^*$ sufficiently close to s_1^*. Thus, either $p_s \ll 0$ and $q_s \gg 0$ for each $s \in (s_1^*, s_2^*)$, or there exist $s_0 \in (s_1^*, s_2^*)$ and $t \in \mathbb{R}$ such that $p_{s_0} \leqslant 0$ and $q_{s_0} \geqslant 0$ and either $p_{s_0}(t) = 0$, or $q_{s_0}(t) = 0$. Since

$$-cv(s_0)p_{s_0} + \dot{\mu}(s_0)mv(s_0) > 0,$$

we find from Proposition 2.1 applied to the second equation of (7.17) that $q_{s_0} \gg 0$. Thus, $-bu(s_0)q_{s_0} < 0$ and, thanks again to Proposition 2.1, the first equation of (7.17) gives $p_{s_0} \ll 0$, which is impossible. Therefore, for each $s \in (s_1^*, s_2^*)$, $p_s \ll 0$ and $q_s \gg 0$, which concludes the proof of (7.23). The proof of the theorem is completed. □

7.4. *Some bifurcation diagrams*

In order to study the curves $\mathfrak{C}_\lambda^\mu$ we did carried out some numerical investigations in [12], where we solved (1.2) using spectral collocation methods coupled with path-following techniques. To compute T-periodic solutions of (1.2), the most appropriate set of basis functions to use is trigonometric polynomials, and these were used to generate the bifurcation diagrams of Figs. 17 and 18. Fig. 17 shows the approximated components $\mathfrak{C}_\lambda^\mu$ for the following problems, with $T = 1$ and $a = d = 1$,

(a) $\mu = 3.32$, $m(t) = 1 + 0.7\sin(2\pi t)$, $\ell(t) = 1 + 0.7\cos(2\pi t)$, $b(t) = 0.9 + 0.7\sin(2\pi t + \pi/4)$, $c(t) = 0.9 + 0.7\cos(2\pi t + \pi/4)$.

(b) $\mu = 3.32$, $m(t) = 1 + 0.7\sin(2\pi t)$, $\ell(t) = 1 + 0.7\cos(2\pi t)$, $b(t) = 0.9 + 0.7\sin(2\pi t)$, $c(t) = 0.9 + 0.7\cos(2\pi t)$.

(c) $\mu = 5.00$, $\ell(t) = m(t) = 1 + 0.7\sin(2\pi t)$, $b(t) = c(t) = 0.9 + 0.7\sin(2\pi t)$.

(d) $\mu = 3.32$, $\ell(t) = m(t) = 1 - 0.7\sin(2\pi t)$, $b(t) = c(t) = 1.1 + 0.7\sin(2\pi t)$.

Given a $\mu > 0$, we have plotted the parameter λ along the horizontal axis, and along the vertical one we give the value $\frac{\|u\|_2}{2} + \|v\|_2$, where

$$\|f\|_2 = \sqrt{\sum_{j=1}^{\infty} c_j^2} \quad \text{if} \quad f = c_1 + \sum_{j=1}^{\infty} \left[c_{2j}\sin(2\pi jt) + c_{2j+1}\cos(2\pi jt)\right].$$

This particular choice of norm makes it easy to distinguish between the semi-trivial states $(\lambda, \mu, \theta_{[\lambda\ell,a]}, 0)$ and $(\lambda, \mu, 0, \theta_{[\mu m,d]})$, which would otherwise cross near the bifurcation points and confuse the picture. Stable solutions are represented by continuous lines, unstable ones by dashed lines. Several different cases are shown according to the nature of the

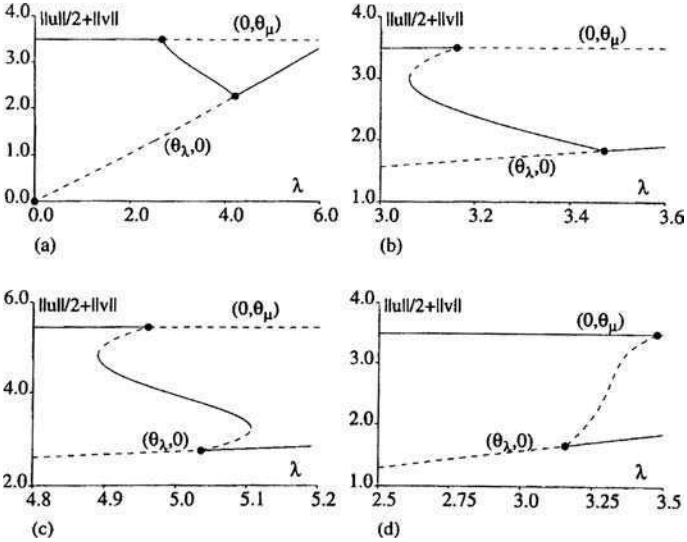

Fig. 17. Bifurcation diagrams for $\mu > 0$ constant.

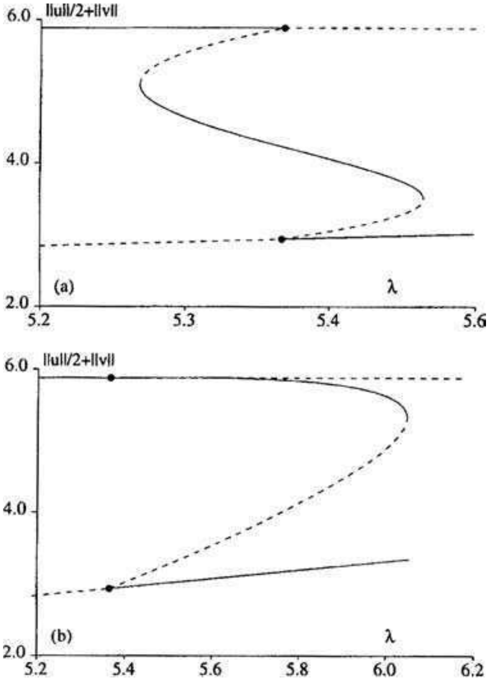

Fig. 18. Two examples with both semi-trivial states neutrally stable.

bifurcation to coexistence states from the semi-trivial solutions. In all cases, $\mathfrak{C}_\lambda^\mu$ possesses at most a finite number of hysteresis and turning points and the stability of the coexistence states change according to Theorem 7.7. Fig. 18 shows some of the possible situations when both semi-trivial states are neutrally stable. In some cases, (1.2) possesses a coexistence states, while in others it does not. Fig. 18 shows the following two cases, with $T=1$ and $a=d=1$:

(a) $\mu = 5.365$, $m(t) = 1 + 0.7\sin(2\pi t)$, $\ell(t) = 1 + 0.7\cos(2\pi t)$, $b(t) = c(t) = 0.9 + 0.7\sin(2\pi t)$.

(b) $\mu = 5.365$, $m(t) = 1 + 0.7\sin(2\pi t)$, $\ell(t) = 1 + 0.7\cos(2\pi t)$, $b(t) = 0.9 + 0.7\sin(2\pi t)$, $c(t) = 0.9 + 0.7\cos(2\pi t)$.

Case (a) provides us with an example where both semi-trivial states are neutrally stable and (1.2) does not admit a coexistence state. It should be noted that, thanks to the discussion closing Section 7.3, (1.2) cannot admit a further coexistence state outside $\mathfrak{C}_\lambda^\mu$. Case (b) provides us with an example where both semi-trivial states are neutrally stable and (1.2) possesses a unique coexistence state, which is stable.

7.5. *Dynamics of* (1.1)

Thanks to the theory developed by P. de Mottoni and A. Schiaffino [29], all solutions of (1.1) must approach a T-periodic solution of (1.2) as time passes by. Combining this information with the theory developed in this section, one can easily obtain the validity of the following assertions. Subsequently, we shall denote by $(u(t), v(t))$ the unique positive solution of (1.1).

1. If $\lambda \leqslant 0$ and $\mu \leqslant 0$, then $\lim_{t\uparrow\infty} (u(t), v(t)) = (0,0)$.
2. If $\lambda > 0$ and $\mu \leqslant 0$, then

$$\lim_{t\uparrow\infty} \big(u(t), v(t)\big) = (\theta_{[\lambda\ell,a]}, 0). \tag{7.33}$$

3. If $\lambda \leqslant 0$ and $\mu > 0$, then

$$\lim_{t\uparrow\infty} \big(u(t), v(t)\big) = (0, \theta_{[\mu m,d]}). \tag{7.34}$$

4. If

$$\lambda > 0, \quad 0 < \mu < \frac{1}{T}\int_0^T c(t)\theta_{[\lambda\ell,a]}(t)\,\mathrm{d}t, \tag{7.35}$$

   and (1.2) does not admit a coexistence state, then, (7.33) holds true.
5. If (7.35) is satisfied, and (1.2) has a coexistence state, then, either (7.33) holds true, or there exists a coexistence state (u_0, v_0) of (1.2) such that

$$\lim_{t\uparrow\infty} \big(u(t), v(t)\big) = (u_0, v_0). \tag{7.36}$$

Moreover, in this case the number of stable coexistence states of (1.2) equals the number of unstable coexistence states, if there is some.

6. If

$$\mu > 0, \quad 0 < \lambda < \frac{1}{T}\int_0^T b(t)\theta_{[\mu m,d]}(t)\,\mathrm{d}t, \tag{7.37}$$

and (1.2) does not admit a coexistence state, then, (7.34) holds true.

7. If (7.37) is satisfied and (1.2) has a coexistence state, then, either (7.34) holds true, or there exists a coexistence state (u_0, v_0) of (1.2) satisfying (7.36). Moreover, in this case the number of stable coexistence states of (1.2) equals the number of unstable coexistence states, if there is some.
8. If

$$\lambda > \frac{1}{T}\int_0^T b(t)\theta_{[\mu m,d]}(t)\,\mathrm{d}t, \quad \mu > \frac{1}{T}\int_0^T c(t)\theta_{[\lambda\ell,a]}(t)\,\mathrm{d}t, \tag{7.38}$$

then (1.2) possesses a stable coexistence state. Moreover, if $n \geqslant 1$ stands for its number of stable coexistence states, then (1.2) possesses $n-1$ unstable coexistence states and a finite number of neutrally stable coexistence states. Furthermore, there exists a coexistence state (u_0, v_0) for which (7.36) holds true.

9. If

$$0 < \lambda < \frac{1}{T}\int_0^T b(t)\theta_{[\mu m,d]}(t)\,\mathrm{d}t, \quad 0 < \mu < \frac{1}{T}\int_0^T c(t)\theta_{[\lambda\ell,a]}(t)\,\mathrm{d}t,$$

then (1.2) possesses an unstable coexistence state. Moreover, if $n \geqslant 1$ stands for its number of unstable coexistence states, then (1.2) possesses $n-1$ stable coexistence states and a finite number of neutrally stable coexistence states. Furthermore, either there exists a coexistence state (u_0, v_0) for which (7.36) holds, or either (7.33), or (7.34), holds, according to the values of (x, y).

8. The species v preys on u ($b > 0$ and $c < 0$)

Now, the linearization of (1.2) around any coexistence state can be expressed in the form

$$\begin{cases} u' = \alpha u - \beta v, \\ v' = \gamma u + \rho v, \end{cases} \tag{8.1}$$

where $\alpha, \beta, \gamma, \rho \in \mathcal{C}_T$ satisfy

$$\int_0^T \alpha < 0, \quad \int_0^T \rho < 0, \quad \beta > 0, \quad \gamma > 0, \tag{8.2}$$

which is a non-cooperative periodic system. As a result, the nice monotonicity properties available for competing species and symbiotic models are lost, and, in general, the components of coexistence states $\mathfrak{C}^{\lambda}_{\mu}$ and $\mathfrak{C}^{\mu}_{\lambda}$ bifurcating from the semi-trivial states are far from being analytic curves, except in a neighborhood of their bifurcation points from the semi-trivial states. Nevertheless, in strong contrast with the classical cases of competition and symbiosis, in this model the existence of a coexistence state is characterized by the linear stability of the semi-trivial states.

8.1. *Characterizing the existence of coexistence states*

Subsequently, we suppose $m \gg 0$ and $d \gg 0$. Then,

$$\lim_{\mu\uparrow\infty} \frac{1}{T}\int_0^T b(t)\theta_{[\mu m,d]}(t)\,\mathrm{d}t = \infty,$$

since

$$\lim_{\mu\uparrow\infty} \frac{\theta_{[\mu m,d]}}{\mu} = \frac{m}{d},$$

and, hence, for each $\lambda > 0$ there exists a unique value of μ, $\mu_* > 0$, such that

$$\lambda = \frac{1}{T}\int_0^T b(t)\theta_{[\mu_* m,d]}(t)\,\mathrm{d}t. \tag{8.3}$$

The following result is satisfied.

THEOREM 8.1. *The following conditions are equivalent*:

(a) *Problem* (1.2) *possesses a coexistence state.*

(b) $\lambda > 0$ *and any semi-trivial state of* (1.2) *is linearly unstable.*

(c) *The parameters* (λ, μ) *satisfy*

$$\lambda > \max\left\{0, \frac{1}{T}\int_0^T (b\theta_{[\mu m,d]})\right\}, \quad \mu > \frac{1}{T}\int_0^T (c\theta_{[\lambda\ell,a]}), \tag{8.4}$$

where, for each $\mu \in \mathbb{R}$, $\theta_{[\mu m,d]} \in \mathcal{C}^1_T$ *stands for the maximal non-negative solution of* $u' = \lambda\ell u - au^2$. *In other words,* $\theta_{[\mu m,d]} \gg 0$ *if* $\mu > 0$, *while* $\theta_{[\mu m,d]} = 0$ *if* $\mu \leqslant 0$.

Moreover, for each $\lambda > 0$, *the component* $\mathfrak{C}^{\lambda}_{\mu}$ *of coexistence states constructed in Theorem* 5.4 *is bounded in* $\mathbb{R} \times \mathcal{C}_T \times \mathcal{C}_T$ *and it satisfies*

$$(\lambda, \mu_0, \theta_{[\lambda\ell,a]}, 0), (\lambda, \mu_*, 0, \theta_{[\mu_* m,d]}) \in \bar{\mathfrak{C}}^{\lambda}_{\mu}, \tag{8.5}$$

where μ_* *is the unique value of* μ *satisfying* (8.3). *Therefore, the* μ*-projection of* $\mathfrak{C}^{\lambda}_{\mu}$ *is the interval* (μ_0, μ_*).

PROOF. Suppose (λ, μ, u_0, v_0) is a coexistence state of (1.2). Then, dividing by u_0 the u-equation and integrating in $[0, T]$ gives

$$\lambda = \frac{1}{T}\int_0^T (au_0 + bv_0) > 0.$$

So, $\lambda > 0$ is necessary for the existence. Subsequently, we will assume that $\lambda > 0$. Then, thanks again to the u-equation,

$$u_0' = \lambda \ell u_0 - au_0^2 - bu_0 v_0 < \lambda \ell u_0 - au_0^2,$$

and, due to Proposition 2.6,

$$u_0 \ll \theta_{[\lambda\ell, a]}. \tag{8.6}$$

So, dividing by v_0 the v-equation, integrating in $[0, T]$, and using (8.6) shows that

$$\mu = \frac{1}{T}\int_0^T (cu_0 + dv_0) > \frac{1}{T}\int_0^T c(t)\theta_{[\lambda\ell,a]}(t)\,\mathrm{d}t,$$

since $c < 0$. Thus, the second estimate of (8.4) is necessary for the existence.

Now, suppose $\mu > 0$. Then, $\theta_{[\mu m, d]} \gg 0$,

$$v_0' = \mu m v_0 - dv_0^2 - cu_0 v_0 > \mu m v_0 - dv_0^2,$$

and, it is apparent from Proposition 2.6 that

$$v_0 \gg \theta_{[\mu m, d]}. \tag{8.7}$$

Consequently,

$$\lambda = \frac{1}{T}\int_0^T (au_0 + bv_0) > \frac{1}{T}\int_0^T b(t)\theta_{[\mu m,d]}(t)\,\mathrm{d}t$$

and, therefore, (8.4) is necessary for the existence of a coexistence state. It should be noted that (8.4) provides us with the set of values of (λ, μ) with $\lambda > 0$ for which any semi-trivial state of (1.2) is linearly unstable, i.e., (b) and (c) are equivalent and we have just seen that (a) implies (c).

Now, fix $\lambda > 0$ and pick $(\mu, u_0, v_0) \in \mathfrak{C}_\mu^\lambda$. Then, (8.7) is satisfied. Moreover, at any time t_0 where $v_0(t_0) = (v_0)_M$, we have that $v_0'(t_0) = 0$ and, hence, it follows from the v-equation that

$$\mu m(t_0) - d(t_0)v_0(t_0) - c(t_0)u_0(t_0) = 0.$$

Thus, thanks to (8.6),

$$\begin{aligned}\|v_0\|_{\mathcal{C}_T} = v_0(t_0) &= \frac{m(t_0)}{d(t_0)}\mu + \frac{-c(t_0)}{d(t_0)}u(t_0)\\ &\leqslant \left(\frac{m}{d}\right)_M |\mu| + \left(\frac{-c}{d}\right)_M \theta_{[\lambda\ell,a]},\end{aligned}$$

and, consequently, $\mathfrak{C}^{\lambda}_{\mu}$ is bounded. Now, it is apparent that Theorem 5.4 concludes the proof. Indeed, the μ-projection of $\mathfrak{C}^{\lambda}_{\mu}$ must be the interval (μ_0, μ_*) and, therefore, (8.4) is sufficient for the existence of a coexistence state of (1.2). □

8.2. *Dynamics of* (1.1)

Thanks to the theory developed in [25], the following results, whose proofs are omitted here, are satisfied. Subsequently, we shall denote by $(u(t), v(t))$ the unique positive solution of (1.1).

1. If $(0,0)$ is linearly stable, i.e., if $\lambda \leqslant 0$ and $\mu \leqslant 0$, then $\lim_{t\uparrow\infty}(u(t), v(t)) = (0,0)$.
2. If $\lambda > 0$ and $(\theta_{[\lambda\ell,a]}, 0)$ is linearly stable, i.e., $\mu \leqslant \frac{1}{T}\int_0^T c(t)\theta_{[\lambda\ell,a]}(t)\,\mathrm{d}t$, then $\lim_{t\uparrow\infty}(u(t), v(t)) = (\theta_{[\lambda\ell,a]}, 0)$.
3. If $\mu > 0$ and $(0, \theta_{[\mu m,d]})$ is linearly stable, i.e., $\lambda \leqslant \frac{1}{T}\int_0^T b(t)\theta_{[\mu m,d]}(t)\,\mathrm{d}t$, then $\lim_{t\uparrow\infty}(u(t), v(t)) = (0, \theta_{[\mu m,d]})$.

As far as to the problem of the uniqueness, multiplicity and stability of the coexistence states things are much more difficult to deal with than in the competing species and symbiotic prototype counterparts, since the linearization of (1.2) at any coexistence state has a *non-cooperative structure*—the off-diagonal entries of the coupling matrix of the system have contrary signs—and for such problems a general comparison principle within the spirit of Theorems 6.1 and 7.1 is far from being available. Therefore, the problem of ascertaining the signs of the Floquet exponents of a given coexistence state is extremely difficult to treat with.

Quite strikingly, although the one-dimensional predator–prey model with diffusion under homogeneous Dirichlet boundary conditions is known to admit at most a coexistence state [26,10,18], there are choices of the several coefficient functions in the setting of (1.2) for which the predator–prey model admits two $2T$-periodic coexistence states and one unstable T-periodic coexistence state [5,8,18]. Hence, the uniqueness result for the one-dimensional elliptic model does not extend in general to the periodic prototype models, however both prototypes, viewed as abstract non-cooperative systems, possess the same operator structure [18]. In [25] were obtained some persistence results in the presence of coexistence states, and in [5] it was shown that if the product of the interactions b and c is sufficiently small, then the model admits at most a coexistence state, though we refrain of giving more details here. Actually, this uniqueness principle holds true in the general case when b and c are arbitrary. The details will appear elsewhere.

1. Introduction

The evolution of a physical system in time is described by an initial value problem, i.e. a differential equation (ordinary or partial) and an initial condition. In many cases it is better to have more initial information. The local condition is replaced then by a nonlocal condition, which gives better effect than the local initial condition, since the measurement given by a nonlocal condition is usually more precise than the only one measurement given by a local condition.

The study of initial value problems (IVP for short) with nonlocal conditions is of significance, since they have applications in problems in physics and other areas of applied mathematics. Conditions of this type can be applied in the theory of elasticity with better effect than the initial or Darboux conditions.

Consider the differential equation

$$x'(t) = f\big(t, x(t)\big), \quad x(t_0) = x_0, \quad t \geqslant 0,\ x(t) \in \mathbb{R}^n. \tag{1.1}$$

The fundamental assumption used when modeling a system using a differential equation is that the time rate at time t, given as $x'(t)$, depends only on the current status at time t, given as $f(t, x(t))$. Moreover, the initial condition is given in the form $x(t_0) = x_0$. In applications, this assumption and the initial condition should be improved so that we can model the situations more accurately and therefore derive better results.

One improvement of Eq. (1.1) is to assume that the time rate depends not only on the current status, but also on the status in the past; that is, the past history will contribute to the future development, or, there is a *time-delay* effect.

Another improvement of Eq. (1.1) is the so-called *differential equations with nonlocal conditions*. That is, we extend the initial condition (also called *local condition*)

$$x(t_0) = x_0$$

to the following *nonlocal condition*

$$x(t_0) + g\big(x(\cdot)\big) = x_0, \tag{1.2}$$

where $x(\cdot)$ denotes a solution (that is, $x(\cdot)$ is a function) and g is a mapping defined on some space consisting of certain functions. (Of course, g may be identically zero, in which case it reduces to the local condition or initial condition $x(t_0) = x_0$.) The advantage of using nonlocal conditions is that measurements at more places can be incorporated to get better models.

1.1. *Examples of nonlocal conditions*

Let $p \in \mathbb{N}$ and let $t_1, t_2, \ldots, t_p$ be given real numbers such that

$$t_0 < t_1 < t_2 < \cdots < t_p \leqslant t_0 + \alpha.$$

Then g can be defined by the formula

$$g(x)=\sum_{i=1}^{p} c_i x(t_i), \tag{1.3}$$

where c_i, $i=1,2,\dots,p$ are given constants or by the relation

$$g(x)=\sum_{i=1}^{p} \frac{c_i}{\epsilon_i}\int_{t_i-\epsilon_i}^{t_i} x(t)\,\mathrm{d}t, \tag{1.4}$$

where ϵ_i, $i=1,2,\dots,p$ are given positive constants such that: $t_{i-1}<t_i-\epsilon_i<t_i$, $i=1,2,\dots,p$. Particularly, if $x_0=0$, $p=1$, $t_1=t_0+\alpha$ then

$$u(t_0)=-c_1 x(t_0+\alpha) \quad \text{and} \quad x(t_0)=\frac{-c_1}{\epsilon_1}\int_{t_0+\alpha-\epsilon_1}^{t_0+\alpha} x(t)\,\mathrm{d}t$$

respectively.

The constants c_i, $i=1,2,\dots,p$ in the nonlocal condition (1.3) can satisfy the inequalities $|c_i|>1$, $i=1,2,\dots,p$. It is remarkable that if $c_i\neq 0$, $i=1,2,\dots,p$ the results can be applied to kinematics to determine the evolution $t\to x(t)$ of the location of a physical object for which we do not know the positions $x(0), x(t_1),\dots,x(t_p)$, but we know that the nonlocal condition of (1.3) holds. Consequently, to describe some physical phenomena, the nonlocal condition can be more useful than the standard initial condition $x(0)=x_0$. From the nonlocal condition of (1.3) it is clear that when $c_i=0$, $i=1,2,\dots,p$ we have the classical initial condition.

Let us have one more example for partial differential equations. In the theory of diffusion and heat conduction one can encounter a mathematical model of the form:

$$\begin{aligned}
&Lx+c(w,t)x=f(w,t), \quad t\in\Omega,\ 0<t<T,\\
&x(w,t)=\phi(w,t), \quad w\in\partial\Omega,\ 0<t<T,\\
&x(w,0)+\sum_{k=1}^{N}\beta_k(w)x(w,t_k)=\psi(w), \quad w\in\Omega \text{ and } t_k\in(0,T],\ k=1,\dots,N,
\end{aligned}$$

where Ω is a bounded region in $\mathbb{R}^n$ and L is a uniformly parabolic operator with continuous and bounded coefficients. It represents the diffusion phenomenon of a small amount of gas in a transparent tube. If there is very little gas at the initial time, the measurement $x(w,0)$ of the amount of the gas in this instant may be less precise that the measurement $x(w,0)+\sum_{k=1}^{N}\beta_k(x)x(w,t_k)$ of the sum of the amount of this gas.

2. Nonlocal initial value problems

Here, we consider the following initial value problem

$$x' = f(t,x), \quad t \in I := [t_0, T],\ x \in \mathbb{R}^n, \tag{2.1}$$

$$x(t_0) + g\big(x(\cdot)\big) = x_0, \tag{2.2}$$

where $x(\cdot)$ denotes a solution and g is a mapping acting on some space of functions defined on $[0, T]$.

Since $g(x(\cdot))$ in Eq. (2.2) is defined on the interval $[t_0, T]$ rather than a single point, the IVP (2.1)–(2.2) is called an "*initial value problem with nonlocal conditions*" or "*nonlocal initial value problem*", and can be applied with better effect than just using the classical initial value problem with $x(t_0) = x_0$, because new measurements at more places are allowed, thus more information is available.

For the IVP (2.1)–(2.2), observe that if x is a solution, then

$$x(t) = x(t_0) + \int_{t_0}^{t} f\big(s, x(s)\big)\,\mathrm{d}s = \big[x_0 - g\big(x(\cdot)\big)\big] + \int_{t_0}^{t} f\big(s, x(s)\big)\,\mathrm{d}s. \tag{2.3}$$

On the other hand, assume that a function x on the interval $[t_0, T]$ satisfies (2.3). For this fixed function x, $g(x(\cdot))$ is a fixed element in $\mathbb{R}^n$, hence $\frac{\mathrm{d}}{\mathrm{d}t} g(x(\cdot)) = 0$. Therefore, if we take a derivative in t, then x is a solution of IVP (2.1)–(2.2). That is, we conclude that a continuous function x is a solution of the IVP (2.1)–(2.2) if and only if

$$x(t) = \big[x_0 - g\big(x(\cdot)\big)\big] + \int_{t_0}^{t} f\big(s, x(s)\big)\,\mathrm{d}s.$$

This leads to a mapping P on $C([t_0, T], \mathbb{R}^n)$ such that

$$(Px)(t) = \big[x_0 - g\big(x(\cdot)\big)\big] + \int_{t_0}^{t} f\big(s, x(s)\big)\,\mathrm{d}s.$$

2.1. *Existence and uniqueness*

Motivated by physical problems, Byszewski and Lakshmikantham [12] considered the following nonlocal IVP

$$x' = f(t,x), \quad t \in I := [t_0, b], \tag{2.4}$$

$$x(t_0) + g\big(t_1, t_2, \ldots, t_p, x(\cdot)\big) = x_0, \tag{2.5}$$

where $t_0 < t_1 < \cdots < t_p < b$, $p \in \mathbb{N}$, $x = (x_1, x_2, \ldots, x_n) \in \Omega$, $x_0 = (x_{10}, \ldots, x_{n0}) \in \Omega$, $f = (f_1, \ldots, f_n) \in C(I \times \Omega, E)$, $g = (g_1, \ldots, g_n) : I^p \times \Omega \to E$, $g(t_1, \ldots, t_p, \cdot) \in$

$C(\Omega, E)$ and $\Omega \subset E$ is a suitable subset. The symbol $g(t_1, \ldots, t_p, x(\cdot))$ is used in the sense that in the place of $\cdot$ we can substitute only elements of the set $\{t_1, \ldots, t_p\}$.

Let $E = E_1 \times E_2 \times \cdots \times E_n$, where E_i, $i = 1, 2, \ldots, n$ are Banach spaces with norm $\|\cdot\|$.

THEOREM 2.1. *Assume that*:

(i) *E is a Banach space with norm $\|\cdot\|$, $x_0 \in E$, and $\Omega := \overline{B(x_0, r)} = \{y\colon \|y - x_0\| \leqslant r\} \subset E$.*

(ii) *There exist constants $L_i > 0$, $i = 1, \ldots, n$ such that*

$$\bigl\| f_i(s, y) - f_i(s, \bar{y}) \bigr\| \leqslant L_i \|y - \bar{y}\|$$

for (s, y), $(s, \bar{y}) \in I \times \Omega$, $i = 1, \ldots, n$.

(iii) *There exist constants $K_i > 0$, $i = 1, \ldots, n$ such that*

$$\bigl\| g_i(t_1, \ldots, t_p, z) - g_i(t_1, \ldots, t_p, \bar{z}) \bigr\| \leqslant K_i \|z - \bar{z}\|, \quad z, \bar{z} \in \Omega,\ i = 1, \ldots, n.$$

(iv) $$(Md + N)\sqrt{n} \leqslant r, \qquad (Ld + K)\sqrt{n} < 1,$$

where

$$M_i = \sup_{(s,y) \in I \times \Omega} \bigl\| f_i(s, y) \bigr\|, \quad N_i = \sup_{z \in \Omega} \bigl\| g(t_1, \ldots, t_p, z) \bigr\|, \quad i = 1, \ldots, n,$$

and

$$d = b - t_0, \quad L = \max_{i=1,\ldots,n} L_i, \quad K = \max_{i=1,\ldots,n} K_i,$$

$$M = \max_{i=1,\ldots,n} M_i, \quad N = \max_{i=1,\ldots,n} N_i.$$

Then there exists a unique solution on the nonlocal IVP (2.4)–(2.5).

PROOF. It is easy to see, that problem (2.4)–(2.5) is equivalent to the integral equation

$$x(t) = x_0 - g\bigl(t_1, \ldots, t_p, x(\cdot)\bigr) + \int_{t_0}^{t} f\bigl(s, x(s)\bigr)\,\mathrm{d}s, \quad t \in I,$$

which is also equivalent to the following system of the integral equations

$$x_i(t) = x_{i0} - g_i\bigl(t_1, \ldots, t_p, x(\cdot)\bigr) + \int_{t_0}^{t} f_i\bigl(s, x(s)\bigr)\,\mathrm{d}s, \quad t \in I,\ i = 1, \ldots, n.$$

We introduce the operator T given by

$$(Ty)(t) := \bigl((T_1 y)(t), \ldots, (T_n y)(t)\bigr), \quad t \in I,$$

where

$$(T_i y)(t) = x_{i0} - g_i\bigl(t_1, \ldots, t_p, x(\cdot)\bigr) + \int_{t_0}^{t} f_i\bigl(s, x(s)\bigr)\,\mathrm{d}s, \quad t \in I,\ i = 1, \ldots, n.$$

Let $X := C(I, \Omega)$. We will show that the operator T maps X into X. We observe that

$$\begin{aligned}
\|Ty - x_0\| &= \left(\sum_{i=1}^{n} \|T_i y - x_{i0}\|^2\right)^{1/2} \\
&= \left(\sum_{i=1}^{n} \Bigl[\sup_{t\in I} \bigl\|(T_i y)(t) - x_{i0}\bigr\|\Bigr]^2\right)^{1/2} \\
&\leqslant \left(\sum_{i=1}^{n} \biggl[\sup_{t\in I} \int_{t_0}^{t} \bigl\|f_i\bigl(s, y(s)\bigr)\bigr\|\,\mathrm{d}s + \bigl\|g_i\bigl(t_1, \ldots, t_p, y(\cdot)\bigr)\bigr\|\biggr]^2\right)^{1/2} \\
&\leqslant \left(\sum_{i=1}^{n} \Bigl[\sup_{t\in I} \bigl(|t - t_0| M_i + N_i\bigr)\Bigr]^2\right)^{1/2} \\
&\leqslant (Md + N)\sqrt{n} \leqslant r,
\end{aligned}$$

for $y \in X$. Therefore $T : X \to X$.

Next, we will show that T is a contraction on X. We have:

$$\begin{aligned}
\|Ty - T\bar{y}\| &= \left(\sum_{i=1}^{n} \|T_i y - T_i \bar{y}\|^2\right)^{1/2} \\
&= \left(\sum_{i=1}^{n} \Bigl[\sup_{t\in I} \bigl\|(T_i y)(t) - (T_i \bar{y})(t)\bigr\|\Bigr]^2\right)^{1/2} \\
&\leqslant \left(\sum_{i=1}^{n} \biggl[\sup_{t\in I} \int_{t_0}^{t} \bigl\|f_i\bigl(s, y(s)\bigr) - f_i\bigl(s, \bar{y}(s)\bigr)\bigr\|\,\mathrm{d}s\right. \\
&\qquad \left. + \bigl\|g_i\bigl(t_1, \ldots, t_p, y(\cdot)\bigr) - g_i\bigl(t_1, \ldots, t_p, \bar{y}(\cdot)\bigr)\bigr\|\biggr]^2\right)^{1/2} \\
&\leqslant \left(\sum_{i=1}^{n} \Bigl[\sup_{t\in I} \bigl(|t - t_0| L_i \bigl\|y(s) - \bar{y}(s)\bigr\| + K_i \bigl\|y(\cdot) - \bar{y}(\cdot)\bigr\|\bigr)\Bigr]^2\right)^{1/2} \\
&\leqslant (Ld + K)\sqrt{n}\|y - \bar{y}\|
\end{aligned}$$

for arbitrary $y, \bar{y} \in X$ which proves that T is a contraction. Hence, by Banach fixed point theorem, in space X there is the only one fixed point of T and this point is the solution of the nonlocal problem (2.4)–(2.5). So, the proof of the theorem is complete. $\square$

Consider now a nonlocal IVP with a special form of the nonlocal initial condition,

$$x'(t) = f\bigl(t, x(t)\bigr), \quad t \in J := [0, T], \tag{2.6}$$

$$x(0) + \sum_{k=1}^{p} c_k x(t_k) = x_0, \tag{2.7}$$

where $0 < t_1 < \cdots < t_p \leqslant T$, $f : J \times E \to E$ is a given function and E is a Banach space with norm $\|\cdot\|$, $x_0 \in E$, $c_k \neq 0$ and $p \in \mathbb{N}$.

By X we denote the Banach space $C(J, E)$ with the standard norm $\|\cdot\|_X$.

DEFINITION 2.2. Assume that $\sum_{k=1}^{p} c_k \neq -1$. A function $x \in X$ is called a mild solution of (2.6)–(2.7) if satisfies the integral equation

$$x(t) = A\left(x_0 - \sum_{k=1}^{p} c_k \int_0^{t_k} f\bigl(s, x(s)\bigr)\,\mathrm{d}s\right) + \int_0^t f\bigl(s, x(s)\bigr)\,\mathrm{d}s,$$

where $A = (1 + \sum_{k=1}^{p} c_k)^{-1}$.

DEFINITION 2.3. A function $x : J \to E$ is said to be a classical solution of the nonlocal problem (2.6)–(2.7) if

(i) x is continuous on J and continuously differentiable on J,
(ii) $x'(t) = f(t, x(t))$ for $t \in J$, and
(iii) $x(0) + \sum_{k=1}^{p} c_k x(t_k) = x_0$.

It is easy to see that if $f \in C(J \times E, E)$ and $\sum_{k=1}^{p} c_k \neq -1$, then x is the unique classical solution of the nonlocal problem (2.6)–(2.7) if and only if x is the unique mild solution of this problem.

THEOREM 2.4. *Assume that*:

(1) $f : J \times E \to E$ *is continuous with respect to the first variable on* J *and there is* $L > 0$ *such that*

$$\bigl\| f(t, z) - f(t, \bar{z}) \bigr\| \leqslant L \sum_{i=1}^{2} \|z - \bar{z}\|$$

for $t \in J$, $z, \bar{z} \in E$.
(2) $\sum_{k=1}^{p} c_k \neq -1$.
(3) $2LT(1 + |A \sum_{k=1}^{p} c_k|) < 1$.

Then the nonlocal IVP (2.6)–(2.7) *has a unique classical solution.*

PROOF. Introduce the operator P by the formula

$$(Px)(t) = A\left(x_0 - \sum_{k=1}^{p} c_k \int_0^{t_k} f\bigl(s, x(s)\bigr)\,\mathrm{d}s\right) + \int_0^t f\bigl(s, x(s)\bigr)\,\mathrm{d}s, \quad t \in J,\ x \in X.$$

It is easy to see that $P : X \to X$. We will prove that P is a contraction on X. We have

$$\begin{aligned}\bigl\|(Px)(t) - (P\bar{x})(t)\bigr\| &= \left\| A\left(-\sum_{k=1}^{p} c_k \int_0^{t_k} \bigl[f\bigl(s, x(s)\bigr) - f\bigl(s, \bar{x}(s)\bigr)\bigr]\,\mathrm{d}s\right)\right.\\ &\qquad \left. + \int_0^t \bigl[f\bigl(s, x(s)\bigr) - f\bigl(s, \bar{x}(s)\bigr)\bigr]\,\mathrm{d}s \right\|\\ &\leqslant 2LT\left(1 + \left|A \sum_{k=1}^{p} c_k\right|\right) \|x - \bar{x}\|_X.\end{aligned}$$

By (3) operator P is a contraction. Consequently by Banach fixed point theorem in space X there is only one fixed point of P and this fixed point is the unique classical solution of the nonlocal IVP (2.6)–(2.7). The proof of the theorem is complete. □

Theorem 2.4 is a special case of Theorem 2.4 of [11], where the functional differential equation $x'(t) = f(t, x(t), x(a(t)))$, $t \in J$ was considered. We point out that when we model some situations from physics and other applied sciences, we typically end up with partial differential equations. In recent years there has been increasing interest in studying evolution differential equations with nonlocal conditions. The interested reader is referred to [10] and [86] and the references cited therein.

3. Nonlocal boundary value problems

Let $f : [0, 1] \times \mathbb{R}^2 \to \mathbb{R}$ be a continuous function and let $e : [0, 1] \to \mathbb{R}$ be a function in $L^1[0, 1]$, $a_i \in \mathbb{R}$, $\xi_i \in (0, 1)$, $i = 1, 2, \ldots, m-2$, $0 < \xi_1 < \xi_2 < \cdots < \xi_{m-2} < 1$. We consider the following second-order ordinary differential equation

$$x''(t) = f\bigl(t, x(t), x'(t)\bigr) + e(t), \quad t \in (0, 1) \tag{3.1}$$

subject to the following boundary value conditions:

$$x(0) = 0, \qquad x(1) = \sum_{i=1}^{m-2} a_i x(\xi_i). \tag{3.2}$$

It is well known, that if a function $x \in C^1[0,1]$ satisfies the boundary conditions (3.2) and all α_i have the same sign then there exists an $\eta \in [\xi_1, \xi_{m-2}]$ such that

$$x(0) = 0, \qquad x(1) = \alpha x(\eta),$$

with $\alpha = \sum_{k=1}^{m-2} a_i$. Accordingly, the problem of the existence of a solution for the boundary value problem (BVP for short) (3.1)–(3.2) can be studied via the existence of a solution of the following three-point BVP

$$x(0) = 0, \qquad x(1) = \alpha x(\eta). \tag{3.3}$$

The above so-called "*nonlocal*" or "*multi-point*" or "*m-point*" BVP was initiated by Il'in and Moiseev in [43,44], motivated by the work of Bitsadze and Samarskii on nonlocal linear elliptic BVPs [7,8]. The nonlocal BVP for ordinary differential equations arise in a variety of different areas of applied mathematics and physics, and describe many phenomena in the applied mathematical sciences. For example, the vibrations of a guy wire of a uniform cross-section and composed on N parts of different densities can be set up as a multi-point BVP (see [83]); many problems in the theory of elastic stability can be handled by the method of multi-point problems (see [90]).

We will study nonlocal BVP for first, second or higher order ordinary differential equations.

3.1. *First-order three-point boundary value problems*

Given $a, b, c \in \mathbb{R}$ with $a < b < c$. Let $J := [a, c]$ and $M_{n\times n}$ the Banach space of all constant matrices of order n with the norm

$$\|B\| = \max_{1\leqslant i,j\leqslant n} |b_{i,j}|.$$

Let $C(J), L^1(J)$, and $AC(J)$ the usual Banach spaces of all continuous functions, all Lebesque integrable functions and all absolutely continuous functions with the norms

$$\|x\|_\infty = \max\bigl\{\bigl|x(t)\bigr|: t \in J\bigr\}, \qquad \|x\|_{L^1} = \int_J \bigl|x(t)\bigr|\,\mathrm{d}t,$$
$$\|x\|_{AC} = \|x\|_\infty + \|x'\|_{L^1},$$

respectively. For $\alpha = (\alpha_1, \dots, \alpha_n) \in \mathbb{R}^n$, define

$$\|\alpha\| = \max\bigl\{|\alpha_i|: i = 1, \dots, n\bigr\}.$$

Denote by X, Y and Z the Banach spaces $C[J, \mathbb{R}^n] = \{(x_1, \dots, x_n): x_i \in C(J)\}$, $L^1[J, \mathbb{R}^n] = \{(x_1, \dots, x_n): x_i \in L^1C(J)\}$, and $AC[J, \mathbb{R}^n] = \{(x_1, \dots, x_n): x_i \in AC(J)\}$ with the norms $\|x\|_X = \max\{\|x_i\|_\infty: i = 2, \dots, n\}$, $\|x\|_Y = \sum_{i=1}^n \|x_i\|_{L^1}$ and $\|x\|_Z = \max\{\|x_i\|_{AC}: i = 2, \dots, n\}$ respectively.

DEFINITION 3.1. We say that $f : J \times \mathbb{R}^n \to \mathbb{R}^n$ is a Carathéodory function if

(i) $f(\cdot, u)$ is Lebesgue measurable on J for each $u \in \mathbb{R}^n$,
(ii) $f(t, \cdot)$ is continuous on $\mathbb{R}^n$ for a.e. $t \in J$,
(iii) for each $r \in (0, \infty)$, there exists an $h_r \in L^1(J, \mathbb{R}^n)$ such that

$$\left|f_i(t, u)\right| \leqslant (h_r)_i(t), \quad \text{for a.e. } t \in J,\ \|u\| \leqslant r,\ i = 1, \dots, n.$$

We study the problem of existence of solutions for the three-point BVP

$$x'(t) = f\bigl(t, x(t)\bigr), \quad \text{for a.e. } t \in J, \tag{3.4}$$

$$Mx(a) + Nx(b) + Rx(c) = \alpha, \tag{3.5}$$

where $f : [a, c] \times \mathbb{R}^n \to \mathbb{R}^n$ is a Carathéodory function, $M, N, R \in M_{n\times n}$, and $\alpha \in \mathbb{R}^n$ are given.

THEOREM 3.2. *Let $f : [a, c] \times \mathbb{R}^n \to \mathbb{R}^n$ be a Carathéodory function and $\alpha \in \mathbb{R}^n$. Assume that*

(A1) *M, N, R are constant square matrices of order n such that*

$$\det(M + N + R) \neq 0.$$

(A2) *There exist functions $p, r \in L^1(J)$ such that*

$$\left\|f(t, u)\right\| \leqslant p(t)\|u\| + r(t),$$

for a.e. $t \in J$ and $u \in \mathbb{R}^n$.

Then the three-point BVP (3.4)–(3.5) *has at least one solution in $C(J, \mathbb{R}^n)$ provided*

$$\Gamma \|p\|_1 < 1,$$

where

$$\Gamma = \max\Bigl\{\left\|(M + N + R)^{-1}R\right\|, \left\|(M + N + R)^{-1}M\right\|, \left\|(M + N + R)^{-1}(N + R)\right\|, \left\|(M + N + R)^{-1}(N + M)\right\|\Bigr\}.$$

PROOF. Let $e(\cdot) \in L^1(J, \mathbb{R}^n)$ and $\alpha \in \mathbb{R}^n$, $x \in AC(J)$ be such that

$$x'(t) = e(t), \quad \text{for a.e. } t \in J,$$

$$Mx(a) + Nx(b) + Rx(c) = \alpha.$$

Then

$$x(t) = \int_a^t e(s)\,\mathrm{d}s + (M + N + R)^{-1}\left[\alpha - N\int_a^b e(s)\,\mathrm{d}s - R\int_a^c e(s)\,\mathrm{d}s\right].$$

If E is the identity matrix, for $a \leqslant t \leqslant b < c$, we have

$$\begin{aligned} x(t) = & \int_a^t \bigl[E - (M+N+R)^{-1}N - (M+N+R)^{-1}R\bigr]e(s)\,\mathrm{d}s \\ & - \int_t^b \bigl[(M+N+R)^{-1}N + (M+N+R)^{-1}R\bigr]e(s)\,\mathrm{d}s \\ & - \int_b^c \bigl[(M+N+R)^{-1}R\bigr]e(s)\,\mathrm{d}s \\ = & \int_a^t (M+N+R)^{-1}Me(s)\,\mathrm{d}s \\ & - \int_t^b (M+N+R)^{-1}(N+R)e(s)\,\mathrm{d}s \\ & - \int_b^c (M+N+R)^{-1}Re(s)\,\mathrm{d}s, \end{aligned}$$

and hence

$$\begin{aligned} \bigl\|x(t)\bigr\| \leqslant \max\bigl\{ & \bigl\|(M+N+R)^{-1}M\bigr\|, \bigl\|(M+N+R)^{-1}(N+R)\bigr\|, \\ & \bigl\|(M+N+R)^{-1}R\bigr\|\bigr\}\|e\|_Y. \end{aligned}$$

For $a \leqslant b \leqslant t \leqslant c$ we have

$$\begin{aligned} x(t) = & \int_a^b \bigl[E - (M+N+R)^{-1}N - (M+N+R)^{-1}R\bigr]e(s)\,\mathrm{d}s \\ & - \int_b^t \bigl[-E + (M+N+R)^{-1}R\bigr]e(s)\,\mathrm{d}s \\ & - \int_t^c \bigl[(M+N+R)^{-1}R\bigr]e(s)\,\mathrm{d}s \\ = & \int_a^b (M+N+R)^{-1}Me(s)\,\mathrm{d}s \\ & - \int_b^t (M+N+R)^{-1}(-M-N)e(s)\,\mathrm{d}s \\ & - \int_t^c (M+N+R)^{-1}Re(s)\,\mathrm{d}s, \end{aligned}$$

and hence

$$\begin{aligned} \bigl\|x(t)\bigr\| \leqslant \max\bigl\{ & \bigl\|(M+N+R)^{-1}M\bigr\|, \bigl\|(M+N+R)^{-1}(M+N)\bigr\|, \\ & \bigl\|(M+N+R)^{-1}R\bigr\|\bigr\}\|e\|_Y. \end{aligned}$$

By combining the above relations we get

$$\left|x(t)\right| \leqslant \Gamma \|e\|_1$$

where

$$\Gamma = \max\bigl\{ \bigl\|(M+N+R)^{-1}R\bigr\|, \bigl\|(M+N+R)^{-1}M\bigr\|, \\ \bigl\|(M+N+R)^{-1}(N+R)\bigr\|, \bigl\|(M+N+R)^{-1}(N+M)\bigr\| \bigr\}.$$

It is obvious that, if $e = 0$, then the problem

$$x'(t) = 0, \quad \text{for a.e. } t \in J,$$
$$Mx(a) + Nx(b) + Rx(c) = \alpha,$$

has the unique solution $x(t) = w$, where

$$w = (M+M+R)^{-1}\alpha.$$

Moreover the problem

$$x'(t) = f(t,x), \quad \text{for a.e. } t \in J,$$
$$Mx(a) + Nx(b) + Rx(c) = \alpha,$$

has a solution $x = y_1 + w$ if and only if y_1 is a solution of

$$y'(t) = f(t, y+w), \quad \text{for a.e. } t \in J, \tag{3.6}$$
$$My(a) + Ny(b) + Ry(c) = 0. \tag{3.7}$$

Now we define $L : D(L) \subset X \to Y$ by

$$D(L) = \bigl\{ y \in AC(J)\colon\ My(a) + Ny(b) + Ry(c) = 0 \bigr\},$$

and for $y \in D(L)$,

$$Ly = y'.$$

We also define a nonlinear mapping $G : X \to X$ by

$$Gy = f\bigl(t, y(t) + w\bigr), \quad t \in J.$$

We note that G is a bounded operator from X into Y. Next it is easy to see from (A1) that the linear mapping $L : D(L) \subset X \to Y$, is a one-to-one mapping. Let the linear mapping $K : Y \to X$ be defined for $e \in Y$ by

$$(Ke)(t) = \int_a^t e(s)\,\mathrm{d}s + (M+M+R)^{-1}\biggl[\alpha - N\int_a^b e(s)\,\mathrm{d}s - R\int_a^c e(s)\,\mathrm{d}s\biggr].$$

Then for $e \in Y$, we have $Ke \in D(L)$ and $LKe = e$. For $y \in D(L)$, we have $KLy = y$. Furthermore, it follows easily using the Arzelá–Ascoli theorem that KG maps a bounded subset of X into a relatively compact subset of X. Hence, $KG: X \to X$ is a compact mapping.

We next note that $y \in C(J, \mathbb{R}^n)$ is a solution of BVP (3.6)–(3.7) if and only if y is a solution to operator equation

$$Ly - Gy,$$

which is equivalent to the equation

$$y = KGy.$$

We apply the Leray–Schauder continuation theorem (see, e.g., [82, Corollary IV.7]) to obtain existence of a solution to $y = KGy$ or equivalently to the BVP (3.6)–(3.7).

To do this, it suffices to verify that the set of all possible solutions of the family of equations

$$y'(t) = \lambda f(t, y + w), \quad \text{for a.e. } t \in J, \tag{3.8}$$

$$My(a) + Ny(b) + Ry(c) = 0, \tag{3.9}$$

is bounded in $X = C(J, \mathbb{R}^n)$ by a constant independent of $\lambda \in [0, 1]$.

Let $y(t)$ be a solution of (3.8)–(3.9) for some $\lambda \in [0, 1]$. It follows from our assumptions that $f(t, y(t) + w(t)) \in L^1(J, \mathbb{R}^n)$. We have

$$\begin{aligned} \|y\|_X &\leqslant \lambda \Gamma \big\| f\big(t, y(t) + w\big)\big\|_Y \\ &\leqslant \Gamma\big[\|p\|_{L^1}\|y + w\|_X + \|r\|_{L^1}\big] \\ &\leqslant \Gamma\big[\|p\|_{L^1}\big(\|y\|_X + \|w\|_X\big) + \|r\|_{L^1}\big]. \end{aligned}$$

It follows from $\Gamma\|p\|_{L^1} < 1$ that there exists a constant c_0, independent of $\lambda \in [0, 1]$, such that

$$\|y\|_X \leqslant c_0.$$

This completes the proof of the theorem. □

THEOREM 3.3. *Let* $f : [a, c] \times \mathbb{R}^n \to \mathbb{R}^n$ *be a Carathéodory function and* $\alpha \in \mathbb{R}^n$. *Assume that* (A1) *holds. Moreover we suppose that*

(A3) *There exists function* $p \in L^1(J)$ *such that*

$$\big\| f(t, u) - f(t, v)\big\| \leqslant p(t)\|u - v\|$$

for a.e. $t \in J$ *and all* $u, v \in \mathbb{R}^n$.

Then the three-point BVP (3.4)–(3.5) *has a unique solution in* $C(J, \mathbb{R}^n)$ *provided*

$$\Gamma \|p\|_1 < 1.$$

PROOF. We note that (A3) implies

$$\|f(t,u)\| \leqslant \|f(t,0)\| + p(t)\|u\|,$$

for a.e. $t \in J$ and all $u \in \mathbb{R}^n$. Hence the BVP (3.4)–(3.5) has at least one solution in $C(J, \mathbb{R}^n)$ by Theorem 3.2. Suppose that u_1, u_2 are two solutions of (3.4)–(3.5) in $C(J, \mathbb{R}^n)$. Setting $z = u_1 - u_2$, we have

$$z' = f\bigl(t, u_1(t)\bigr) - f\bigl(t, u_2(t)\bigr),$$
$$Mz(a) + Nz(b) + Rz(c) = 0.$$

Then we have

$$\begin{aligned}\|z\|_X &\leqslant \lambda\Gamma \bigl\| f\bigl(t, u_1(t)\bigr) - f\bigl(t, u_2(t)\bigr)\bigr\|_Y \\ &\leqslant \Gamma\bigl(\|p\|_{L^1}\|u_1 - u_2\|_X\bigr) \\ &\leqslant \Gamma\|p\|_{L^1}\|z\|_X,\end{aligned}$$

which implies that $z(t) = 0$, for $t \in J$ and hence $u_1 = u_2$. This completes the proof of the theorem. □

Theorems 3.2 and 3.3 were taken from [74]. Existence and uniqueness of solutions of the BVP (3.4)–(3.5) were studied in [84] by using the successive over relaxation iteration and the Banach contraction mapping principle.

3.2. *Second-order three-point boundary value problems*

In this section we consider the following three-point BVP

$$x''(t) = f\bigl(t, x(t), x'(t)\bigr) + e(t), \quad t \in (0,1) \tag{3.10}$$

$$x(0) = 0, \qquad x(1) = x(\eta), \tag{3.11}$$

where $f : [0,1] \times \mathbb{R}^2 \to \mathbb{R}$, $e : [0,1] \to \mathbb{R}$ are given functions and $\eta \in (0,1)$.

We will study the existence and uniqueness of the BVP (3.10)–(3.11). We use the classical spaces $C[0,1]$, $C^k[0,1]$, $L^k[0,1]$, and $L^\infty[0,1]$ of continuous, k-times continuously differentiable, measurable real valued functions whose kth power of the absolute value is Lebesgue integrable on $[0,1]$, or measurable functions that are essentially bounded on $[0,1]$. We also use the Sobolev space $W^{2,k}(0,1)$, $k = 1, 2$ defined by

$$W^{2,k}(0,1) = \bigl\{x : [0,1] \to \mathbb{R}\colon\ x, x' \text{are absolutely continuous on } [0,1] \text{ with } x \in L^k[0,1]\bigr\}$$

with its usual norm. We denote the norm in $L^k[0,1]$ by $\|\cdot\|_k$, and the norm in $L^\infty[0,1]$ by $\|\cdot\|_\infty$.

The BVP (3.10)–(3.11) can be put in the form of an operator equation

$$Lx + Nx = w,$$

where $L : D(L) \subset X \to Y$ is a linear operator, $N : X \to Y$ is a nonlinear operator, and X, Y are suitable spaces in duality. Clearly the linear operator L in (3.10) is given by

$$Lx = -x''$$

where the boundary conditions (3.11) are used to define the domain, $D(L)$, of L.

We begin by giving the following definition.

DEFINITION 3.4. A function $f : [0,1] \times \mathbb{R}^2 \to \mathbb{R}$ satisfies Carathéodory's conditions if:

(i) for each $(x,y) \in \mathbb{R}^2$, the function $t \in [0,1] \to f(t,x,y) \in \mathbb{R}$ is measurable on $[0,1]$,

(ii) for a.e. $t \in [0,1]$, the function $(x,y) \in \mathbb{R}^2 \to f(t,x,y) \in \mathbb{R}$ is continuous on $\mathbb{R}^2$, and

(iii) for each $r > 0$, there exists $g_r \in L^1[0,1]$ such that $|f(t,x,y)| \leqslant g_r(t)$ for a.e. $t \in [0,1]$ and $(x,y) \in \mathbb{R}^2$ with $\sqrt{x^2+y^2} \leqslant r$.

In the next existence theorems, we obtain appropriate *a priori* bounds by applying degree theory. We use Wirtinger-type inequalities to obtain the necessary a priori bounds needed to apply the Leray–Schauder continuation theorem [82, Corollary IV.7].

THEOREM 3.5. *Let $f : [0,1] \times \mathbb{R}^2 \to \mathbb{R}$ satisfy Carathéodory's conditions. Assume that there exist functions $p, q, r \in L^1[0,1]$ such that*

$$\bigl|f(t,u,v)\bigr| \leqslant p(t)|u| + q(t)|v| + r(t), \tag{3.12}$$

for a.e. $t \in [0,1]$ and all $(u,v) \in \mathbb{R}^2$. Then for every given function $e \in L^1[0,1]$, the BVP (3.10)–(3.11)*, has at least one solution in $C^1[0,1]$ provided*

$$\|q\|_1 \leqslant 1,$$

and

$$\sqrt{\eta}\,\|p\|_{L^1[\eta,1]} \frac{1 - \|q\|_{L^1[0,1]}}{1 - \|q\|_{L^1[\eta,1]}} + \|p\|_{L^1[0,1]} + \|q\|_{L^1[0,1]} < 1.$$

PROOF. Let X be the Banach space $C^1[0,1]$ and Y denote the Banach space $L^1(0,1)$ with their usual norms. We define a linear mapping $L : D(L) \subset X \to Y$ by setting

$$D(L) = \bigl\{x \in W^{2,1}(0,1):\ x(0) = 0,\ x(1) = x(\eta)\bigr\},$$

and for $x \in D(L)$,

$$Lx = -x''.$$

We also define a nonlinear mapping $N : X \to Y$ by setting

$$(Nx)(t) = f\bigl(t, x(t), x'(t)\bigr), \quad t \in [0, 1].$$

We note that N is a bounded mapping from X into Y. Next, it is easy to see that the linear mapping $L : D(L) \subset X \to Y$, is one-to-one mapping. Next, the linear mapping $K : Y \to X$, defined for $y \in Y$ by

$$(Ky)(t) = -\int_0^t (t-s)y(s)\,\mathrm{d}s + t\int_0^\eta y(s)\,\mathrm{d}s + \frac{t}{1-\eta}\int_0^1 (1-s)y(s)\,\mathrm{d}s$$

is such that for $y \in Y$, $Ky \in D(L)$ and $LKy = y$; and for $u \in D(L)$, $KLu = u$. Furthermore, it follows easily using the Arzelá–Ascoli theorem that KN maps a bounded subset of X into a relatively compact subset of X. Hence $KN : X \to X$ is a compact mapping.

We next note that $x \in C^1[0, 1]$ is a solution of the BVP (3.10)–(3.11) if and only if x is a solution to the operator equation

$$Lx = Nx + e.$$

Now, the operator equation $Lx = Nx + e$ is equivalent to the equation

$$x = KNx + Ke.$$

We apply the Leray–Schauder continuation theorem (see, e.g., [82, Corollary IV.7]) to obtain the existence of a solution for $x = KNx + Ke$ or equivalently to the BVP (3.10)–(3.11).

To do this, it suffices to verify that the set of all possible solutions of the family of equations

$$x''(t) = \lambda f\bigl(t, x(t), x'(t)\bigr) + \lambda e(t), \quad t \in (0, 1), \tag{3.13}$$

$$x(0) = 0, \qquad x(1) = x(\eta), \tag{3.14}$$

is, a priori, bounded in $C^1[0, 1]$ by a constant independent of $\lambda \in [0, 1]$.

We observe first that for $x \in W^{2,1}(0, 1)$ with $x(0) = 0, x(1) = x(\eta)$ there exists a $\zeta \in (0, 1)$, $\eta < \zeta < 1$, such that $x'(\zeta) = 0$. It follows that

$$\|x\|_2 \leqslant \frac{2}{\pi}\|x'\|_2, \qquad \|x\|_\infty \leqslant \|x'\|_2,$$

$$\bigl|x(1)\bigr| = \bigl|x(\eta)\bigr| = \left|\int_0^\eta x'(t)\,\mathrm{d}t\right| \leqslant \sqrt{\eta}\|x'\|_2,$$

$$\left|x'(1)\right| = \left|\int_\zeta^1 x''(t)\,\mathrm{d}t\right| \leqslant \int_\zeta^1 \left|x''(t)\right|\mathrm{d}t.$$

We multiply Eq. (3.13) by x and integrate from 0 to 1 to get

$$\begin{aligned}
0 &= -\int_0^1 x''(t)x(t)\,\mathrm{d}t + \lambda\int_0^1 f\big(t,x(t),x'(t)\big)x(t)\,\mathrm{d}t - \lambda\int_0^1 e(t)x(t)\,\mathrm{d}t \\
&\geqslant \|x'\|_2^2 - \left|x'(1)\right|\left|x(1)\right| - \int_0^1 \left|f\big(t,x(t),x'(t)\big)\right|\left|x(t)\right|\mathrm{d}t - \|e\|_1\|x\|_\infty \\
&\geqslant \|x'\|_2^2 - \left|x'(1)\right|\left|x(1)\right| \\
&\quad - \int_0^1 \left[p(t)\left|x(t)\right|^2 + q(t)\left|x(t)\right|\left|x'(t)\right| + r(t)\left|x(t)\right|\right]\mathrm{d}t - \|e\|_1\|x\|_\infty \\
&\geqslant \|x'\|_2^2 - \sqrt{\eta}\|x'\|_2\|x''\|_{L^1[\eta,1]} \\
&\quad - \left[\|p\|_1\|x\|_2^2 + \|q\|_1\|x\|_\infty\|x'\|_\infty + \|r\|_1\|x\|_\infty\right] - \|e\|_1\|x\|_\infty \\
&\geqslant \|x'\|_2^2 - \sqrt{\eta}\|x'\|_2\|x''\|_{L^1[\eta,1]} - \left[\|p\|_1\|x'\|_2^2 + \|q\|_1\|x'\|_2\|x''\|_1\right] \\
&\quad - \big(\|r\|_1 + \|e\|_1\big)\|x'\|_2.
\end{aligned}$$

From Eq. (3.13) we have

$$\begin{aligned}
\|x''\|_1 &\leqslant \|p\|_1\|x\|_\infty + \|q\|_1\|x'\|_\infty + \|r\|_1 \\
&\leqslant \|p\|_1\|x'\|_2 + \|q\|_1\|x''\|_1 + \|r\|_1,
\end{aligned}$$

so that

$$\|x''\|_1 \leqslant \frac{\|p\|_1\|x'\|_2}{1-\|q\|_1} + \frac{\|r\|_1}{1-\|q\|_1}.$$

Similarly we have

$$\|x''\|_{L^1[\eta,1]} \leqslant \frac{\|p\|_{L^1[\eta,1]}\|x'\|_2}{1-\|q\|_{L^1[\eta,1]}} + \frac{\|r\|_1}{1-\|q\|_{L^1[\eta,1]}}.$$

Consequently

$$\begin{aligned}
&\left\{1 - \|q\|_1 - \sqrt{\eta}\|p\|_{L^1[\eta,1]}\frac{1-\|q\|_1}{1-\|q\|_{L^1[\eta,1]}} - \|p\|_1\right\}\|x'\|_2 \\
&\quad\leqslant \|q\|_1\|r\|_1 + \sqrt{\eta}\|r\|_1\frac{1-\|q\|_1}{1-\|q\|_{L^1[\eta,1]}} + \big(\|r\|_1 + \|e\|_1\big)\big(1-\|q\|_1\big).
\end{aligned}$$

Hence, there exists a constant C, independent of $\lambda \in [0,1]$ such that $\|x'\|_2 \leqslant C$. It follows that there is a constant, still denoted by C, independent of $\lambda \in [0,1]$ such that

$$\|x\|_{C^1[0,1]} \leqslant C.$$

This completes the proof of the theorem. □

THEOREM 3.6. *Let* $f:[0,1]\times\mathbb{R}^2 \to \mathbb{R}$ *satisfy Carathéodory's conditions. Assume that* $a \geqslant 0, b \geqslant 0, \alpha(t) \in L^1[0,1]$ *are such that*

$$\left|f(t,u,v)\right| \leqslant a|u| + b|v| + \alpha(t),$$

for a.e. $t \in [0,1]$ *and all* $(u,v) \in \mathbb{R}^2$*. Then for every given function* $e(t) \in L^1[0,1]$*, the BVP* (3.10)–(3.11) *has at least one solution in* $C^1[0,1]$ *provided*

$$\left(\frac{2}{\pi}a + b\right)\left(\frac{2}{\pi} + \sqrt{\eta(1-\eta)}\right) < 1.$$

PROOF. As in the proof of Theorem 3.5 it suffices to verify that the set of all possible solutions of the family of equations (3.13)–(3.14) is a priori bounded in $C^1[0,1]$ by a constant independent of $\lambda \in [0,1]$.

Letting x to be a solution of (3.13)–(3.14) for some $\lambda \in [0,1]$ we get, as in Theorem 3.5, that

$$\begin{aligned}
0 &= -\int_0^1 x''(t)x(t)\,\mathrm{d}t + \lambda\int_0^1 f\bigl(t,x(t),x'(t)\bigr)x(t)\,\mathrm{d}t - \lambda\int_0^1 e(t)x(t)\,\mathrm{d}t \\
&\geqslant \|x'\|_2^2 - \left|x'(1)\right|\left|x(1)\right| - \int_0^1 \bigl[a|x|^2 + b|x||x'| + \alpha(t)|x|\bigr]\,\mathrm{d}t - \|e\|_1\|x\|_\infty \\
&\geqslant \|x'\|_2^2 - \sqrt{\eta}\|x'\|_2\|x''\|_{L^1[\eta,1]} - a\|x\|_2^2 - b\|x\|_2\|x'\|_2 \\
&\quad - \bigl(\|\alpha\|_1 + \|e\|_1\bigr)\|x\|_\infty \\
&\geqslant \|x'\|_2^2 - \sqrt{\eta}\|x'\|_2\|x''\|_{L^1[\eta,1]} - \left(\frac{4}{\pi^2}a + \frac{2}{\pi}b\right)\|x'\|_2^2 - \bigl(\|\alpha\|_1 + \|e\|_1\bigr)\|x'\|_2.
\end{aligned}$$

Also

$$\begin{aligned}
\|x''\|_{L^1[\eta,1]} &\leqslant \left\|f\bigl(t,x(t),x'(t)\bigr)\right\|_{L^1[\eta,1]} + \|e\|_1 \\
&\leqslant a\int_\eta^1 |x|\,\mathrm{d}x + b\int_\eta^1 |x'|\,\mathrm{d}x + \|\alpha\|_1 + \|e\|_1 \\
&\leqslant \sqrt{1-\eta}\left(\frac{2}{\pi}a + b\right)\|x'\|_2 + \|\alpha\|_1 + \|e\|_1.
\end{aligned}$$

Consequently

$$\|x'\|_2 \leqslant \frac{(\|\alpha\|_1 + \|e\|_1)(1+\sqrt{\eta})}{1-((2/\pi)a+b)(2/\pi+\sqrt{\eta(1-\eta)})}.$$

It then follows as in proof of Theorem 3.5 that there exists a constant C independent of $\lambda \in [0,1]$ such that $\|x\|_{C^1[0,1]} \leqslant C$, which proves the theorem. □

We give now a uniqueness result for the BVP (3.10)–(3.11).

THEOREM 3.7. *Let* $f : [0,1] \times \mathbb{R}^2 \to \mathbb{R}$ *satisfy Carathéodory's conditions. Assume that* $a \geqslant 0$, $b \geqslant 0$, *are such that*

$$\bigl|f(t,u_1,v_1) - f(t,u_2,v_2)\bigr| \leqslant a|u_1-u_2| + b|v_1-v_2|, \tag{3.15}$$

for a.e. $t \in [0,1]$ *and all* $(u_i,v_i) \in \mathbb{R}^2, i = 1,2$. *Then for every given function* $e(t) \in L^1[0,1]$, *the BVP* (3.10)–(3.11) *has unique solution in* $C^1[0,1]$ *provided*

$$\left(\frac{2}{\pi}a + b\right)\left(\frac{2}{\pi} + \sqrt{\eta(1-\eta)}\right) < 1.$$

PROOF. We note that (3.15) implies that

$$\bigl|f(t,u,v)\bigr| < a|u| + b|v| + \bigl|f(t,0,0)\bigr|$$

for all $t \in [0,1]$ and all $(u,v) \in \mathbb{R}^2$. Hence the BVP (3.10)–(3.11) has a solution by Theorem 3.6. Let now u_1, u_2 be two solutions of (3.10)–(3.11) in $C^1[0,1]$. Setting $w = u_1 - u_2$ we have

$$w'' = f(t,u_1,u_1') - f(t,u_2,u_2'), \quad t \in (0,1), \tag{3.16}$$

$$w(0) = 0, \qquad w(1) = w(\eta). \tag{3.17}$$

Multiplying Eq. (3.16) by w and integrating over $[0,1]$ we get

$$\begin{aligned}
0 = {} & -\int_0^1 w''w\,\mathrm{d}t + \int_0^1 \bigl[f\bigl(t,u_1(t),u_1'(t)\bigr) - f\bigl(t,u_2(t),u_2'(t)\bigr)\bigr]w(t)\,\mathrm{d}t \\
\geqslant {} & \|w'\|_2^2 - \bigl|w(1)\bigr|\bigl|w'(1)\bigr| \\
& - \int_0^1 \bigl|f\bigl(t,u_1(t),u_1'(t)\bigr) - f\bigl(t,u_2(t),u_2'(t)\bigr)\bigr|\bigl|w(t)\bigr|\,\mathrm{d}t \\
\geqslant {} & \|w'\|_2^2 - \sqrt{\eta}\|w'\|_2\|w''\|_{L^1[\eta,1]} \\
& - \int_0^1 \bigl[a|u_1-u_2|^2 + b|u_1'-u_2'||u_1-u_2|_2\bigr]\,\mathrm{d}t
\end{aligned}$$

$$\geqslant \|w'\|_2^2 - \sqrt{\eta}\|w'\|_2\|w''\|_{L^1[\eta,1]} - \left(\frac{4}{\pi^2}a + \frac{2}{\pi}b\right)\|w'\|_2^2.$$

But

$$\begin{aligned}\|w''\|_{L^1[\eta,1]} &= \left\| f\big(t, u_1(t), u_1'(t)\big) - f\big(t, u_2(t), u_2'(t)\big)\right\|_{L^1[\eta,1]} \\ &\leqslant \sqrt{1-\eta}\left(\frac{2}{\pi}a + b\right)\|w'\|_2^2,\end{aligned}$$

and consequently

$$\left(1 - \left(\sqrt{\eta(1-\eta)} + \frac{2}{\pi}\right)\left(\frac{2}{\pi}a + b\right)\right)\|w'\|_2^2 \leqslant 0,$$

so that $\|w'\|_2 = 0$. Since $w(0) = 0$ we obtain using $w(t) = \int_0^t w'(t)\,\mathrm{d}t$ that $\|w\|_\infty \leqslant \|w'\|_2 = 0$. Hence $w = 0$ a.e. in $[0,1]$ and thus $w(t) = 0$ for every $t \in [0,1]$ because w is continuous. □

Theorems 3.5–3.7 were proved by Gupta in [25]. By means of rather different approach based on an existence theorem for operator inclusions, Marano proved in [80], that if p, q, r are in $L^1[0,1]$ and (3.12) holds, then the BVP (3.10)–(3.11) has at least one generalized solution $x \in W^{2,1}[0,1]$ provided

$$\|p\|_1 + \|q\|_1 < 1,$$

which is an improvement of Theorem 3.5. For this result of Marano, Gupta in [26] gave a simple proof by using degree theory and Wirtinger-type inequalities. Marano in [80] proved also that if p, q, r are in $L^2[0,1]$ and (3.12) holds, then the BVP (3.10)–(3.11) has at least one generalized solution $x \in W^{2,1}[0,1]$ provided

$$\frac{\sqrt{\eta}+1}{\pi}\|p\|_2 + \|q\|_2 < 1.$$

In the case when p, q, r are in $L^2(0,1)$, and (3.12) holds, Gupta in [32] proved that the BVP (3.10)–(3.11) has at least one generalized solution $x \in C^1[0,1]$ provided

$$\frac{2}{\pi}\|p\|_2 + \|q\|_2 < 1.$$

The Leray–Schauder continuation theorem can be used without the use of Wirtinger-type inequalities and using instead Green's functions. The Green's functions for various BVPs are easily computed. Then one uses Green's functions to reduce the BVPs to integral equations. Thus finding a priori estimates can be realized by estimating the norms of integral operators, which can be solved by Green's functions and its derivatives. In this direction Zhang and Han [93] proved that if p, q, r are in $L^1[0,1]$ and (3.12) holds, then the BVP (3.10)–(3.11) has at least one solution in $C^1[0,1]$ provided

$$\max\biggl\{\int_0^\eta \bigl(sp(s)+q(s)\bigr)\,\mathrm{d}s + \int_\eta^1 \frac{1-s}{1-\eta}\bigl(sp(s)+q(s)\bigr)\,\mathrm{d}s, \\ \int_\eta^1 \frac{s-\eta}{1-\eta}\bigl(sp(s)+q(s)\bigr)\,\mathrm{d}s\biggr\} < 1.$$

In [9] Boucherif and Bouguima proved the existence of solutions of the BVP (3.10)–(3.11) by considering two types of nonlinearities, continuous and Carathéodory's nonlinearities. The methods used in the first case rely on the topological transversality theorem of Granas [14], and in the second case on the technique of cut-off functions. They motivated their results by the remark that if $f(t,u,v) = u + v + R(t,u,v)$ with $R(t,u,v) \leqslant r(t)$ for a.e. $t \in [0,1]$ then f satisfies condition (3.12) i.e. $|f(t,u,v)| \leqslant p_0(t)|u| + q_0|v| + r(t)$ but $\|p_0\|_1 + \|q_0\|_1 = 2 > 1$.

THEOREM 3.8. *Let* $f : [0,1] \times \mathbb{R}^2 \to \mathbb{R}$ *be a continuous function satisfying the following conditions*:

(f1) *there exists* $r > 0$ *such that*

$$\int_0^t f\bigl(s, x(s), x'(s)\bigr)x(s)\,\mathrm{d}s > 0 \quad \textit{whenever} \quad \bigl|x(t)\bigr| > r.$$

(f2) $|f(t,u,v)| \leqslant \psi(|v|)$ *for* $(t,u) \in [0,1] \times [-r,r]$, $v \in \mathbb{R}$ *where* $\psi : [0,\infty) \to (0,\infty)$ *is such that* $1/\psi$ *is integrable over bounded intervals in* $[0,\infty)$ *and* $\int_0^{+\infty} \frac{s}{\psi(s)}\,\mathrm{d}s > 2r$.

Then the BVP (3.10)–(3.11) *has at least one solution*.

PROOF. We begin by examining the linear problem

$$x'' = z, \qquad x(0) = 0, \qquad x(1) = x(\eta)$$

where $z \in C([0,1],\mathbb{R})$. This problem has a unique solution $x \in C^2[0,1]$, given by

$$x(t) = \int_0^t (t-s)z(s)\,\mathrm{d}s + t\int_0^\eta z(s)\,\mathrm{d}s + \frac{t}{1-\eta}\int_\eta^1 (1-s)z(s)\,\mathrm{d}s.$$

This relation defines a linear operator $K : C[0,1] \to C^2[0,1]$ such that $x = Kz$ is the unique solution. Moreover $L = K^{-1}$ is defined by

$$D(L) = \bigl\{x \in C^2[0,1]\colon\ x(0) = 0,\ x(1) = x(\eta)\bigr\}, \qquad Lx = x''.$$

For $\lambda \in [0,1]$ consider the one-parameter family of problems

$$x''(t) = \lambda f\bigl(t, x(t), x'(t)\bigr), \quad t \in (0,1), \tag{3.18}$$

$$x(0) = 0, \qquad x(1) = x(\eta). \tag{3.19}$$

We shall prove that any solution x of (3.18)–(3.19) is a priori bounded, independently of λ.

Let x be a solution of (3.18)–(3.19). If $\lambda = 0$ then $x = 0$ and so $\|x\|_0 = 0 < r$. Assume $0 < \lambda \leqslant 1$. Then λf satisfies (f1). Suppose x takes on a positive maximum at $t_0 \in [0,1]$. Then $x'(t_0) = 0$ and $x''(t_0) \leqslant 0$. Now, if $x(t_0) > r$ it follows from (f1) that

$$\int_0^{t_0} x''(s)x(s)\,\mathrm{d}s = x(t_0)x'(t_0) - \int_0^{t_0} x'(s)^2\,\mathrm{d}s > 0.$$

Since $x'(t_0) = 0$ we have a contradiction. Hence $x(t_0) \leqslant r$ and therefore $\|x\|_0 \leqslant r$. Note that $t_0 \neq 0$ since $x(0) = 0$. Also, the case $t_0 = \eta$ or $t_0 = 1$ leads to a contradiction.

Now we want to show that there exists a constant m_0, such that $|x'(t)| \leqslant m_0$ for all $t \in [0,1]$. Suppose on the contrary that for all positive constants m, there exists $t_0 \in (0,1]$ such that $x'(t_0) > m$ or $x'(t_0) < -m$. We will assume only the case $x'(t_0) > m$, since the other case can be handled in a similar way. Let $\tau \in (0,1)$ be such that $x'(\tau) = 0$ and $x'(t) > 0$ for all $t \in (\tau, t_0]$. This implies that

$$x''(t) \leqslant \psi\bigl(x'(t)\bigr) \quad \text{for all } t \in [\tau, t_0].$$

Hence

$$\frac{x''(t)x'(t)}{\psi(x'(t))} \leqslant x'(t) \quad \text{for all } t \in [\tau, t_0].$$

Integrating this inequality from τ to t_0 we get

$$\int_0^{x'(t_0)} \frac{s}{\psi(s)}\,\mathrm{d}s \leqslant 2r.$$

It follows from the assumptions on ψ that there exists a constant $\tilde{m}$ such that $x'(t_0) \leqslant \tilde{m}$, and so we get a contradiction.

Since f is continuous, we have $|x''(t)| \leqslant m_1 := \sup\{|f(t,u,v)|\colon\ 0 \leqslant t \leqslant 1, \|u\|_0 \leqslant r, \|v\|_0 \leqslant m_0\}$. Hence $\|x''\|_0 \leqslant m_1$. Finally, let $M = \max(r, m_0, m_1)$. Then we get, from $\|x\| = \max(\|x\|_0, \|x'\|_0, \|x''\|_0)$ that $\|x\| \leqslant M$, and M is independent of λ.

We apply the topological transversality of Granas [14]. Let $U = \{x \in D(L)\colon\ \|x\| < M + 1\}$, and $j : D(L) \to C^1[0,1]$ with $j(x) = x$, the natural embedding. The Nemitskii operator $F : C^1[0,1] \to C[0,1]$ is defined by $F(x)(t) := f(t, x(t), x'(t))$ for all $t \in [0,1]$.

For $0 \leqslant \lambda \leqslant 1$ define a family of mappings

$$H_\lambda : \overline{U} \to D(L) \quad \text{by } H_\lambda(x) = \lambda KFj(x).$$

H_λ is a compact homotopy which has no fixed points on the boundary ∂U of U. Since the constant map H_0 is essential, the topological transversality theorem implies that H_1 is essential i.e. has a fixed point. This completes the proof. $\square$

In the case of Carathéodory's nonlinearities we state the following result whose proof is given in [9].

THEOREM 3.9. *Let* $f:[0,1]\times\mathbb{R}^2\to\mathbb{R}$ *be a function satisfying Carathéodory's conditions. Assume that*

(f) $|f(t,u,v)|\leqslant\omega(t,|u|+|v|)$ *for a.e.* $t\in[0,1]$ *and all* $(u,v)\in\mathbb{R}^2$ *where* $\omega:[0,1]\times\mathbb{R}^+\to\mathbb{R}^+$ *is nondecreasing in its second argument and*

$$\lim_{\rho\to\infty}\frac{1}{\rho}\int_0^1\omega(t,\rho)\,\mathrm{d}t=0.$$

Then the BVP (3.10)–(3.11) *has at least one solution.*

3.3. *Third-order three-point boundary value problems*

In this section we consider third-order three-point BVPs. The existence and uniqueness of third-order BVPs deserve a good deal of attention, since they occur in a wide variety of applications. For example, a three-layer beam is formed by parallel layers of different materials. For an equally loaded beam of this type, has shown that the deflection ψ is governed by an ordinary third-order linear differential equation

$$\psi'''-K^2\psi'+a=0,$$

where K^2 and a are physical parameters depending on the elasticity of the layers. The condition of zero moment at the free ends implies the boundary conditions

$$\psi'(0)=\psi'(1)=0,$$

and the symmetry yields the third boundary condition

$$\psi(1/2)=0.$$

We will study existence and uniqueness of the following three-point BVP

$$x'''(t)=f\big(t,x(t),x'(t),x''(t)\big)+e(t),\quad t\in(0,1),\tag{3.20}$$

$$x(0)=x(\eta)=x(1)=0\tag{3.21}$$

where $e:[0,1]\to\mathbb{R}$ is a function in $L^1[0,1]$, $\eta\in(0,1)$, and $f:[0,1]\times\mathbb{R}^3\to\mathbb{R}$ is a function satisfying Carathéodory's conditions, that is

(i) for each $(x,y,z)\in\mathbb{R}^3$, the function $t\in[0,1]\to f(t,x,y,z)\in\mathbb{R}$ is measurable on $[0,1]$,

(ii) for a.e. $t\in[0,1]$, the function $(x,y,z)\in\mathbb{R}^3\to f(t,x,y,z)\in\mathbb{R}$ is continuous on $\mathbb{R}^3$, and

(iii) for each $r > 0$, there exists $g_r \in L^1[0,1]$ such that $|f(t,x,y,z)| \leqslant g_r(t)$ for a.e. $t \in [0,1]$ and $(x,y,z) \in \mathbb{R}^3$ with $\sqrt{x^2+y^2+z^2} \leqslant r$.

THEOREM 3.10. *Let $f : [0,1] \times \mathbb{R}^3 \to \mathbb{R}$ satisfy Carathéodory's conditions. Assume that*

(i) *there exist $a, b, c \in \mathbb{R}$ and $\alpha(t) \in L^1[0,1]$ such that*

$$f(t,x,y,z)y \geqslant ay^2 + b|y||x| + c|y||z| + \alpha(x)y,$$

for a.e. $t \in [0,1]$ and all $(x,y,z) \in \mathbb{R}^3$;

(ii) *there exist functions p, q, r in $L^2[0,1]$ and a function $S(t) \in L^1[0,1]$ such that*

$$\bigl|f(t,x,y,z)\bigr| \leqslant p(t)|x| + q(t)|y| + r(t)|z| + S(t),$$

for a.e. $t \in [0,1]$ and all $(x,y,z) \in \mathbb{R}^3$.

Let $\eta \in (0,1)$ be given. Then for any given function $e \in L^1[0,1]$, the tree-point BVP (3.20)–(3.21) *has at least one solution in $C^2[0,1]$ provided*

$$\frac{4}{\pi^2}|a| + \frac{4}{\pi^3}|b| + \frac{2}{\pi}|c| + \frac{2}{\pi^2}\|p\|_2 + \frac{2}{\pi}\|q\|_2 + \|r\|_2 < 1.$$

PROOF. Let X be the Banach space $C^2[0,1]$ and Y denote the Banach space $L^1(0,1)$ with their usual norms. We define a linear mapping $L : D(L) \subset X \to Y$ by setting

$$D(L) = \bigl\{x \in W^{3,1}(0,1)\colon\ x(0) = x(\eta) = x(1) = 0\bigr\},$$

and for $x \in D(L)$,

$$Lx = -x'''.$$

We also define a nonlinear mapping $N : X \to Y$ by setting

$$(Nx)(t) = f\bigl(t, x(t), x'(t), x''(t)\bigr), \quad t \in [0,1].$$

We note that N is a bounded mapping from X into Y. Next, it is easy to see that the linear mapping $L : D(L) \subset X \to Y$, is one-to-one mapping. Next, the linear mapping $K : Y \to X$, defined for $y \in Y$ by

$$(Ky)(t) = \frac{1}{2}\int_0^t (t-s)^2 y(s)\,\mathrm{d}s + Bt + Ct^2,$$

where

$$B = \frac{1}{2\eta(\eta-1)}\int_0^\eta (t-s)^2 y(s)\,\mathrm{d}s + \frac{\eta}{2(1-\eta)}\int_0^1 (t-s)^2 y(s)\,\mathrm{d}s,$$
$$C = \frac{1}{2\eta(1-\eta)}\int_0^\eta (t-s)^2 y(s)\,\mathrm{d}s - \frac{1}{2(1-\eta)}\int_0^1 (t-s)^2 y(s)\,\mathrm{d}s,$$

is such that for $y \in Y$, $Ky \in D(L)$ and $LKy = y$; and for $u \in D(L)$, $KLu = u$. Furthermore, it follows easily using the Arzelá–Ascoli theorem that KN maps a bounded subset of X into a relatively compact subset of X. Hence $KN : X \to X$ is a compact mapping.

We next note that $x \in C^1[0,1]$ is a solution of the BVP (3.20)–(3.21) if and only if x is a solution to the operator equation

$$Lx = Nx + e.$$

Now, the operator equation $Lx = Nx + e$ is equivalent to the equation

$$x = KNx + Ke.$$

We apply the Leray–Schauder continuation theorem (see, e.g., [82, Corollary IV.7]) to obtain the existence of a solution for $x = KNx + Ke$ or equivalently to the BVP (3.20)–(3.21).

To do this, it suffices to verify that the set of all possible solutions of the family of equations

$$x'''(t) = \lambda f\bigl(t, x(t), x'(t), x''(t)\bigr) + \lambda e(t), \quad t \in (0,1), \tag{3.22}$$

$$x(0) = x(\eta) = x(1) = 0, \tag{3.23}$$

is, a priori, bounded in $C^2[0,1]$ by a constant independent of $\lambda \in [0,1]$.

We observe that for $x \in W^{3,1}(0,1)$ with $x(0) = x(\eta) = x(1) = 0$, there exist ξ_1, ξ_2, ξ_3 in $(0,1)$ with $\xi_1 < \eta < \xi_2$, $x'(\xi_1) = x'(\xi_2) = 0$, $x''(\xi_3) = 0$. This gives

$$\|x\|_2 \leqslant \frac{1}{\pi}\|x'\|_2, \qquad \|x'\|_2 \leqslant \frac{2}{\pi}\|x''\|_2,$$

$$\bigl|x'(0)\bigr| = \left|\int_0^{\xi_1} x''(t)\,\mathrm{d}t\right| \leqslant \int_0^{\eta} \bigl|x''(t)\bigr|\,\mathrm{d}t,$$

$$\bigl|x'(1)\bigr| = \left|\int_{\xi_2}^{1} x''(t)\,\mathrm{d}t\right| \leqslant \int_{\eta}^{1} \bigl|x''(t)\bigr|\,\mathrm{d}t,$$

$$\bigl|x''(0)\bigr| = \left|\int_0^{\xi_3} x''(t)\,\mathrm{d}t\right| \leqslant \|x'''\|_1, \qquad \bigl|x''(1)\bigr| = \left|\int_{\xi_3}^{1} x''(t)\,\mathrm{d}t\right| \leqslant \|x'''\|_1.$$

We multiply Eq. (3.22) by x' and integrate from 0 to 1 to get

$$0 = -\int_0^1 x'''(t)x'(t)\,\mathrm{d}t + \lambda\int_0^1 f\bigl(t, x(t), x'(t), x''(t)\bigr)x'(t)\,\mathrm{d}t$$
$$- \lambda\int_0^1 e(t)x'(t)\,\mathrm{d}t$$

$$
\begin{aligned}
&\geqslant \|x''\|_2^2 - |x''(1)||x'(1)| - |x''(0)||x'(0)| \\
&\quad + \lambda \int_0^1 \left\{a x'^2(t) + b|x(t)||x'(t)| + c|x'(t)||x''(t)| + \alpha(t)x'(t)\right\} \mathrm{d}t \\
&\quad - \lambda \|e\|_1 \|x'\|_\infty \\
&\geqslant \|x''\|_2^2 - \left(|x'(0)| + |x'(1)|\right)\|x''\|_1 - |a|\|x'\|_2^2 - |b|\|x\|_2\|x'\|_2 \\
&\quad - |c|\|x'\|_2\|x''\|_2 - \left(\|\alpha\|_1 + \|e\|_1\right)\|x'\|_\infty \\
&\geqslant \|x''\|_2^2 - \left(\int_0^\eta |x''(t)|\,\mathrm{d}t + \int_\eta^1 |x''(t)|\,\mathrm{d}t\right)\|x'''\|_1 \\
&\quad - \left(\frac{4}{\pi^2}|a| + \frac{4}{\pi^3}|b| + \frac{2}{\pi}|c|\right)\|x''\|_2^2 - \left(\|\alpha\|_1 + \|e\|_1\right)\|x''\|_2 \\
&\geqslant \|x''\|_2^2 - \|x''\|_1\|x'''\|_1 - \left(\frac{4}{\pi^2}|a| + \frac{4}{\pi^3}|b| + \frac{2}{\pi}|c|\right)\|x''\|_2^2 \\
&\quad - \left(\|\alpha\|_1 + \|e\|_1\right)\|x''\|_2.
\end{aligned}
$$

From Eq. (3.22) we have

$$
\begin{aligned}
\|x'''\|_1 &\leqslant \|p\|_2\|x\|_2 + \|q\|_2\|x'\|_2 + \|r\|_2\|x''\|_2 + \|S\|_1 + \|e\|_1 \\
&\leqslant \left(\frac{2}{\pi^2}\|p\|_2 + \frac{2}{\pi}\|q\|_2 + \|r\|_2\right)\|x''\|_2 + \|S\|_1 + \|e\|_1.
\end{aligned}
$$

Putting this in the previous inequality we find

$$
\|x''\|_2 \leqslant \frac{\|S\|_1 + 2\|e\|_1 + \|\alpha\|_1}{1 - \left(\frac{4}{\pi^2}|a| + \frac{4}{\pi^3}|b| + \frac{2}{\pi}|c| + \frac{2}{\pi^2}\|p\|_2 + \frac{2}{\pi}\|q\|_2 + \|r\|_2\right)}.
$$

Hence, there exists a constant C, independent of $\lambda \in [0,1]$ such that $\|x'''\|_1 \leqslant C$. It follows that there is a constant, still denoted by C, independent of $\lambda \in [0,1]$ such that

$$
\|x\|_{C^2[0,1]} \leqslant C.
$$

This completes the proof of the theorem. □

In Theorem 3.10 we can do without assumption (i), if we observe that

$$
\begin{aligned}
f(t,x,y,z)y &\geqslant |f(t,x,y,z)||y| \\
&\geqslant -|p(t)||y||x| - |q(t)|y^2 - |r(t)||y||z| - |S(t)||y|.
\end{aligned}
$$

It is easy to see from the proof of Theorem 3.10 that the BVP (3.20)–(3.21) has at least one solution in $C^2[0,1]$ provided

$$\frac{4}{\pi^2}\|p\|_2 + \frac{4}{\pi}\|q\|_2 + 2\|r\|_2 < 1.$$

THEOREM 3.11. *Let $f:[0,1]\times\mathbb{R}^3 \to \mathbb{R}$ satisfy Carathéodory's conditions. Suppose that*

(iii) *there exist functions $p, q, r \in L^2[0,1]$ such that*

$$\begin{aligned}&\left|f(t,x_1,y_1,z_1) - f(t,x_2,y_2,z_2)\right|\\ &\quad \leqslant p(t)|x_1-x_2| + q(t)|y_1-y_2| + r(t)|z_1-z_2|,\end{aligned}$$

for a.e. $t \in [0,1]$ and all $(x_i,y_i,z_i) \in \mathbb{R}^3$, $i=1,2$.

Let $\eta \in (0,1)$ be given. Then for every $e \in L^1[0,1]$ the BVP (3.20)–(3.21) *has exactly one solution in $C^2[0,1]$ provided*

$$\frac{4}{\pi^2}\|p\|_2 + \frac{4}{\pi}\|q\|_2 + 2\|r\|_2 < 1.$$

PROOF. We note that (iii) implies that

$$\left|f(t,x,y,z)\right| \leqslant p(t)|x| + q(t)|y| + r(t)|z| + \left|f(t,0,0,0)\right|$$

for a.e. $t \in [0,1]$ and all $(x,y,z) \in \mathbb{R}^3$. Accordingly the BVP (3.20)–(3.21) has at least one solution in $C^2[0,1]$.

Now, to prove the uniqueness, let x_1, x_2 are two solutions of the BVP (3.20)–(3.21). Setting $u(t) = x_(t) - x_2(t)$ we then get

$$u'''(t) = f\big(t,x_1(t),y_1(t),z_1(t)\big) - f\big(t,x_2(t),y_2(t),z_2(t)\big), \tag{3.24}$$

$$u(0) = u(\eta) = u(1) = 0. \tag{3.25}$$

We multiply Eq. (3.24) by u' and integrate over $[0,1]$ to get

$$\begin{aligned}0 &= -\int_0^1 u'''(t)u'(t)\,\mathrm{d}t\\ &\quad + \int_0^1 \big[f\big(t,x_1(t),y_1(t),z_1(t)\big) - f\big(t,x_2(t),y_2(t),z_2(t)\big)\big]u'(t)\,\mathrm{d}t\\ &\geqslant \|u''\|_2^2 - \|u''\|_2\|u'''\|_1 - \|p\|_2\|u\|_2\|u'\|_\infty - \|q\|_2\|u'\|_2\|u'\|_\infty\\ &\quad - \|r\|_2\|u'\|_\infty\|u''\|_2\\ &\geqslant \|u''\|_2^2 - \|u''\|_2\big(\|p\|_2\|u\|_2 + \|q\|_2\|u'\|_2 + \|r\|_2\|u''\|_2\big)\\ &\quad - \left(\frac{2}{\pi^2}\|p\|_2 + \frac{2}{\pi}\|q\|_2 + \|r\|_2\right)\|u''\|_2^2\end{aligned}$$

$$\geqslant \left(1 - \left[\frac{4}{\pi^2}\|p\|_2 + \frac{4}{\pi}\|q\|_2 + 2\|r\|_2\right]\right)\|u''\|_2^2,$$

hence $\|u''\|_2 = 0$. It now follows from the estimate $\|u\|_2 \leqslant (2/\pi^2)\|u''\|_2$ and the continuity of u that $u(t) = 0$ for every $t \in [0,1]$, i.e. $x_1(t) = x_2(t)$ for every $t \in [0,1]$. This completes the proof of the theorem. □

Theorems 3.10 and 3.11 were proved in [31]. For other results for third-order three-point BVPs the interested reader is referred to [1,24,81] and the references cited therein.

3.4. *m-point boundary value problems reduced to three-point boundary value problems*

Let $f : [0,1] \times \mathbb{R}^2 \to \mathbb{R}$ be either a continuous or a Carathéodory's function and let $e : [0,1] \to \mathbb{R}$ be a function in $L^1[0,1]$, $a_i \in \mathbb{R}$, with all of the a_i's having the same sign, $\xi_i \in (0,1), i = 1,2,\ldots,m-2$, $0 < \xi_1 < \xi_2 < \cdots < \xi_{m-2} < 1$. We consider the following second-order ordinary differential equation

$$x''(t) = f\big(t, x(t), x'(t)\big) + e(t), \quad t \in (0,1) \tag{3.26}$$

subject to one of the following boundary value conditions:

$$x(0) = 0, \qquad x(1) = \sum_{i=1}^{m-2} a_i x(\xi_i), \tag{3.27}$$

$$x'(0) = 0, \qquad x(1) = \sum_{i=1}^{m-2} a_i x(\xi_i), \tag{3.28}$$

$$x(0) = 0, \qquad x'(1) = \sum_{i=1}^{m-2} a_i x'(\xi_i). \tag{3.29}$$

It is well known, that the existence of a solution for these BVPs can be studied via the existence of a solution for Eq. (3.26) subject to one of the following three-point boundary value conditions:

$$x(0) = 0, \qquad x(1) = \alpha x(\eta), \tag{3.30}$$

$$x'(0) = 0, \qquad x(1) = \alpha x(\eta), \tag{3.31}$$

$$x(0) = 0, \qquad x'(1) = \alpha x'(\eta), \tag{3.32}$$

where $\alpha = \sum_{i=1}^{m-2} a_i$ and $\eta \in [\xi_1, \xi_{m-2}]$.

For certain boundary condition case such that the linear operator $Lx = x''$, defined in a suitable Banach space, is invertible, is the so-called *nonresonance* case. Otherwise, the so-called *resonance* case. In the next sections we will give existence results for both, nonresonance and resonance cases.

3.5. *Nonresonance results*

Using the Leray–Schauder continuation theorem (see [82]) we first give an existence result for the three-point BVP (3.26), (3.30) in the case when $\alpha \neq 1$.

THEOREM 3.12. *Let* $f : [0,1] \times \mathbb{R}^2 \to \mathbb{R}$ *be a function satisfying Carathéodory's conditions. Assume that* (3.12) *holds. Also let* $\alpha \in \mathbb{R}$, *and* $\eta \in (0,1)$ *be given. Then the BVP* (3.26), (3.30) *has at least one solution in* $C^1[0,1]$ *provided*

$$\begin{cases} \|p\|_1 + \|q\|_1 < 1, & \text{if } \alpha \leqslant 1, \\ \|p\|_1 + \|q\|_1 < \dfrac{1-\alpha\eta}{\alpha(1-\eta)}, & \text{if } 1 < \alpha < 1/\eta. \end{cases}$$

PROOF. Let X be the Banach space $C^1[0,1]$ and Y denote the Banach space $L^1(0,1)$ with their usual norms. We denote a linear mapping $L : D(L) \subset X \to Y$ by setting

$$D(L) = \{x \in W^{2,1}(0,1)\colon\ x(0) = 0, x(1) = \alpha x(\eta)\},$$

and for $x \in D(L)$,

$$Lx = x''.$$

We also define a nonlinear mapping $N : X \to Y$ by setting

$$(Nx)(t) = f\bigl(t, x(t), x'(t)\bigr), \quad t \in [0,1].$$

We note that N is a bounded mapping from X into Y. Next, it is easy to see that the linear mapping $L : D(L) \subset X \to Y$, is one-to-one mapping. We note that since $\alpha \leqslant 1$, $\alpha \neq 1/\eta$. Next, the linear mapping $K : Y \to X$, defined for $y \in Y$ by

$$(Ky)(t) = \int_0^t (t-s)y(s)\,\mathrm{d}s + \frac{\alpha t}{1-\alpha\eta}\int_0^\eta (\eta - s)y(s)\,\mathrm{d}s \\ - \frac{t}{1-\alpha\eta}\int_0^1 (1-s)y(s)\,\mathrm{d}s$$

is such that for $y \in Y$, $Ky \in D(L)$ and $LKy = y$; and for $u \in D(L)$, $KLu = u$. Furthermore, it follows easily using the Arzelá–Ascoli theorem that KN maps a bounded subset of X into a relatively compact subset of X. Hence $KN : X \to X$ is a compact mapping.

We next note that $x \in C^1[0,1]$ is a solution of the BVP (3.26), (3.30) if and only if x is a solution to the operator equation

$$Lx = Nx + e.$$

Now, the operator equation $Lx = Nx + e$ is equivalent to the equation

$$x = KNx + Ke.$$

We apply the Leray–Schauder continuation theorem (see, e.g., [82, Corollary IV.7]) to obtain the existence of a solution for $x = KNx + Ke$ or equivalently to the BVP (3.26), (3.30).

To do this, it suffices to verify that the set of all possible solutions of the family of equations

$$x''(t) = \lambda f\big(t, x(t), x'(t)\big) + \lambda e(t), \quad t \in (0,1), \tag{3.33}$$

$$x(0) = 0, \qquad x(1) = \alpha x(\eta), \tag{3.34}$$

is, a priori, bounded in $C^1[0,1]$ by a constant independent of $\lambda \in [0,1]$.

We observe that if $x \in W^{2,1}(0,1)$, with $x(0) = 0$, $x(1) = \alpha x(\eta)$, with $\alpha \leqslant 1$, there exists a $\zeta \in (0,1)$ with $x'(\zeta) = 0$. Indeed, suppose that $\alpha \leqslant 1$ and $x'(t) > 0$ for every $t \in (0,1)$. Then $x(t) > 0$ for every $t \in (0,1)$ and $x(t)$ is strictly increasing on $[0,1]$. We then get that $0 < x(1) - x(\eta) = (\alpha - 1)x(\eta) \leqslant 0$, a contradiction. Then we have

$$\|x\|_\infty \leqslant \|x'\|_\infty \leqslant \|x''\|_1. \tag{3.35}$$

Now let $x(t)$ be a solution of (3.33)–(3.34) for some $\lambda \in [0,1]$, so that $x \in W^{2,1}(0,1)$ with $x(0) = 0$, $x(1) = \alpha x(\eta)$. We then get from Eq. (3.33) that

$$\begin{aligned} \|x''\|_1 &= \lambda \big\| f\big(t, x(t), x'(t)\big) + e(t) \big\|_1 \\ &\leqslant \|p\|_1 \|x\|_\infty + \|q\|_1 \|x'\|_\infty + \|r\|_1 + \|e\|_1 \\ &\leqslant \big(\|p\|_1 + \|q\|_1\big)\|x''\|_1 + \|r\|_1 + \|e\|_1. \end{aligned}$$

It follows from the assumption that there is a constant c, independent of $\lambda \in [0,1]$, such that

$$\|x''\|_1 \leqslant c.$$

It is now immediate from (3.35) that the set of solutions of the family of equations (3.33)–(3.34) is, a priori, bounded in $C^1[0,1]$ by a constant independent of $\lambda \in [0,1]$. This completes the proof of the theorem when $\alpha \leqslant 1$.

Let now $\alpha > 1$ and $\eta \in (0,1)$ with $\alpha\eta < 1$. It suffices to verify that the set of all possible solutions of the family of equations (3.33)–(3.34) is, a priori, bounded in $C^1[0,1]$ by a constant independent of $\lambda \in [0,1]$.

For $x \in W^{2,1}(0,1)$, with $x(0) = 0$, $x(1) = \alpha x(\eta)$, if $\alpha > 1$, there exists a $\zeta \in (\eta, 1)$ such that $(\alpha - 1)x(\eta) = x(1) - x(\eta) = (1-\eta)x'(\zeta)$, or $x(\eta) = (1-\eta)/(\alpha - 1)x'(\zeta)$.

Then we have

$$\|x\|_\infty \leqslant \|x'\|_\infty \leqslant \frac{\alpha(1-\eta)}{1-\alpha\eta}.$$

We then see from Eq. (3.33) that

$$\|x''\|_1 = \lambda \big\| f\big(t, x(t), x'(t)\big) + e(t) \big\|_1$$

$$\leqslant \|p\|_1\|x\|_\infty + \|q\|_1\|x'\|_\infty + \|r\|_1 + \|e\|_1$$

$$\leqslant \big(\|p\|_1 + \|q\|_1\big)\left(\frac{\alpha(1-\eta)}{1-\alpha\eta}\right)\|x''\|_1 + \|r\|_1 + \|e\|_1$$

for a solution x of the family of equations (3.33)–(3.34) for some $\lambda \in [0,1]$. It is then immediate that the set of solutions of the family of equations (3.33)–(3.34) is, a priori, bounded in $C^1[0,1]$ by a constant, independent of $\lambda \in [0,1]$. This completes the proof of the theorem. □

Now we study the m-point BVP (3.26)–(3.27) using the a priori estimates that we obtained for the three-point BVP (3.26), (3.30). This is because for every solution $x(t)$ of the BVP (3.26)–(3.27) there exists $\eta \in [\xi_1, \xi_{m-2}]$, depending on $x(t)$, such that $x(t)$ is also a solution of the BVP (3.26), (3.30) with $\alpha = \sum_{i=1}^{m-2} a_i \neq 1$.

THEOREM 3.13. *Let $f:[0,1]\times\mathbb{R}^2 \to \mathbb{R}$ be a function satisfying Carathéodory's conditions. Assume that* (3.12) *holds. Also let $\alpha = \sum_{i=1}^{m-2} a_i$, and $\eta \in (0,1)$ be given. Then the BVP* (3.26)–(3.27) *has at least one solution in $C^1[0,1]$ provided*

$$\begin{cases} \|p\|_1 + \|q\|_1 < 1, & \text{if } \alpha \leqslant 1,\\ \|p\|_1 + \|q\|_1 < \dfrac{1-\alpha\xi_{m-2}}{\alpha(1-\xi_1)}, & \text{if } 1 < \alpha < 1/\xi_{m-2}. \end{cases}$$

PROOF. We will give only the proof for $\alpha = \sum_{i=1}^{m-2} a_i \leqslant 1$; the other case is similar. The proof is quite similar to that of Theorem 3.12 and uses the a priori bounds for the set of solutions of the family of equations (3.33)–(3.34).

Let X be the Banach space $C^1[0,1]$ and Y denote the Banach space $L^1(0,1)$ with their usual norms. We denote a linear mapping $L: D(L) \subset X \to Y$ by setting

$$D(L) = \left\{x \in W^{2,1}(0,1)\colon\ x(0)=0, x(1) = \sum_{i=1}^{m-2} a_i x(\xi_i)\right\},$$

and for $x \in D(L)$,

$$Lx = x''.$$

We also define a nonlinear mapping $N: X \to Y$ by setting

$$(Nx)(t) = f\big(t, x(t), x'(t)\big), \quad t \in [0,1].$$

We note that N is a bounded mapping from X into Y. Next, it is easy to see that the linear mapping $L: D(L) \subset X \to Y$, is one-to-one mapping. Next, the linear mapping $K: Y \to X$, defined for $y \in Y$ by

$$(Ky)(t) = \int_0^t (t-s)y(s)\,\mathrm{d}s + At$$

where A is given by

$$A\left(1-\sum_{i=1}^{m-2}a_i\xi_i\right)=\sum_{i=1}^{m-2}a_i\int_0^{\xi_1}(\xi_i-s)y(s)\,\mathrm{d}s-\int_0^1(1-s)y(s)\,\mathrm{d}s,$$

is such that for $y\in Y$, $Ky\in D(L)$ and $LKy=y$; and for $u\in D(L)$, $KLu=u$. Furthermore, it follows easily using the Arzelá–Ascoli theorem that KN maps bounded subsets of X into a relatively compact subsets of X. Hence $KN:X\to X$ is a compact mapping.

We, next, note that $x\in C^1[0,1]$ is a solution of the BVP (3.26)–(3.27) if and only if x is a solution to the operator equation

$$Lx=Nx+e.$$

Now, the operator equation $Lx=Nx+e$ is equivalent to the equation

$$x=KNx+Ke.$$

We apply the Leray–Schauder continuation theorem to obtain the existence of a solution for $x=KNx+Ke$ or equivalently to the BVP (3.26)–(3.27).

To do this, it suffices to verify that the set of all possible solutions of the family of equations

$$x''(t)=\lambda f\big(t,x(t),x'(t)\big)+\lambda e(t),\quad t\in(0,1), \tag{3.36}$$

$$x(0)=0,\qquad x(1)=\sum_{i=1}^{m-2}a_ix(\xi_i), \tag{3.37}$$

is, a priori, bounded in $C^1[0,1]$ by a constant independent of $\lambda\in[0,1]$.

Let, now, $x(t)$ be a solution of (3.36)–(3.37) for some $\lambda\in[0,1]$, so that $x\in W^{2,1}(0,1)$ with $x(0)=0$, $x(1)=\sum_{i=1}^{m-2}a_ix(\xi_i)$. Accordingly, there exists, an $\eta\in[\xi_1,\xi_{m-2}]$, depending on x, such that $x(t)$ is a solution of the three-point BVP

$$x''(t)=\lambda f\big(t,x(t),x'(t)\big)+\lambda e(t),\quad t\in(0,1),$$

$$x(0)=0,\qquad x(1)=\alpha x(\eta).$$

It then follows, as in the proof of Theorem 3.12 that there is a constant c, independent of $\lambda\in[0,1]$, and $\eta\in[\xi_1,\xi_{m-2}]$, such that

$$\|x\|_\infty\leqslant\|x'\|_\infty\leqslant\|x''\|_1\leqslant c.$$

Thus the set of solutions of the family of equations (3.36)–(3.37) is, a priori, bounded in $C^1[0,1]$ by a constant, independent of $\lambda\in[0,1]$.

This completes the proof of the theorem. □

Theorems 3.12 and 3.13 were proved in [33]. In Theorem 3.12 the functions p, q, r in the condition (3.12) are in $L^1(0,1)$. If p, q are in $L^\infty(0,1)$ and r, e in $L^2(0,1)$ then the BVP (3.26), (3.30) has at least one solution in $C^1[0,1]$ provided

$$\begin{cases} \frac{2}{\pi}\left(\frac{2}{\pi}\|p\|_\infty + \|q\|_\infty\right) < 1, & \text{if } \alpha \leqslant 1, \\ \frac{2}{\pi}\|p\|_\infty + \|q\|_\infty < \frac{\sqrt{2}(1-\alpha\eta)}{\alpha(1-\eta)}, & \text{if } 1 < \alpha < 1/\eta. \end{cases}$$

In the case when $\alpha \geqslant 1$ and $\alpha\eta \neq 1$ we have a sharper condition for the solvability of BVP (3.26), (3.30). Thus, if tp, q, r are in $L^1[0,1]$ and (3.12) holds, then the BVP (3.26), (3.30) has at least one solution in $C^1[0,1]$ provided

$$\begin{cases} \|tp(t)\|_1 + \|q(t)\|_1 < \frac{1-\alpha\eta}{1-\eta}, & \text{if } \alpha\eta \leqslant 1, \\ \|tp(t)\|_1 + \|q(t)\|_1 < \frac{\alpha\eta - 1}{(\alpha-1)\eta} & \text{if } \alpha\eta > 1. \end{cases}$$

The above conditions were proved in [33] and based on a priori estimates obtained by a different method than that was used in Theorem 3.12.

In the case when $\alpha \in \mathbb{R}$, $\alpha \leqslant 1$ Gupta and Trofimchuk in [38] gave constructive conditions for the solvability of the BVP (3.26), (3.30) using the spectral radius of a compact linear operator, and in [39] new solvability conditions based on a new type Wirtinger inequality. For other results see [37].

In the case when $\alpha \in \mathbb{R}$ with $\alpha\eta \neq 1$ a better condition for the solvability of the BVP (3.26), (3.30) is given by Gupta and Trofimchuk in [38]. They proved that, if tp, q, $t[tp+q]$, r are in $L^1[0,1]$ and (3.12) holds, then the BVP (3.26), (3.30) has at least one solution in $C^1[0,1]$ provided

$$\begin{aligned} \max\Bigg\{ &\int_0^\eta \left|\frac{1-\alpha}{1-\alpha\eta} - 1\right| \big[sp(s) + q(s)\big]\,\mathrm{d}s \\ &+ \frac{1}{|1-\alpha\eta|}\int_\eta^1 (1-s)\big[sp(s)+q(s)\big]\,\mathrm{d}s, \\ &\int_\eta^1 \frac{|s-\alpha\eta|}{|1-\alpha\eta|}\big[sp(s)+q(s)\big]\,\mathrm{d}s + \frac{|\alpha-1|}{|1-\alpha\eta|}\int_0^\eta s\big[sp(s)+q(s)\big]\,\mathrm{d}s \Bigg\} < 1. \end{aligned}$$

Moreover, Gupta in [30], when $\alpha \neq 1$ and $\alpha\eta \neq 1$, obtained new a priori estimates which are sharper than those used in the previous theorems. More precisely, he proved that if p, q, r are in $L^1(0,1)$ and (3.12) holds, then the BVP (3.26), (3.30) has at least one solution in $C^1[0,1]$ provided

$$M\|p\|_1 + \frac{1}{1-\tau}\|q\|_1 < 1,$$

where M and τ are appropriate constants.

Finally, we note that in [40] Gupta and Trofimchuk studied examples of three-point BVP by making extensive use of computer algebra systems like Maple and MathCad.

Concerning the uniqueness of the solutions of the BVPs (3.26), (3.30) and (3.26)–(3.27) we have the following results.

THEOREM 3.14. *Let $f:[0,1]\times\mathbb{R}^2\to\mathbb{R}$ be a function satisfying Carathéodory's conditions. Assume that there exist nonnegative constants c, d such that*

$$\bigl|f(t,x_1,x_2)-f(t,y_1,y_2)\bigr|\leqslant c|x_1-x_2|+d|y_1-y_2|$$

for a.e. $t\in[0,1]$ and all $(x_i,x_i)\in\mathbb{R}^2, i=1,2$. Also let $\alpha\in\mathbb{R}$, and $\eta\in(0,1)$ be given. Then the BVP (3.26), (3.30) *has exactly one solution in $C^1[0,1]$ provided*

$$\begin{cases} \dfrac{2}{\pi}\left(\dfrac{2}{\pi}c+d\right)<1, & \text{if } \alpha\leqslant 1,\\ \dfrac{2}{\pi}c+d<\dfrac{\sqrt{2}(1-\alpha\eta)}{\alpha(1-\eta)}, & \text{if } 1<\alpha<1/\eta. \end{cases}$$

PROOF. The existence of a solution for the BVP (3.26), (3.30) follows from Theorem 3.12. Let now $x_1(t), x_2(t)$ be two solutions of the BVP (3.26), (3.30). We then get

$$\begin{aligned} &x_1''(t)-x_2''(t)=f\bigl(t,x_1(t),x_1'(t)\bigr)-f\bigl(t,y_1(t),y_1'(t)\bigr), \quad 0<t<1,\\ &(x_1-x_2)(0)=0, \qquad (x_1-x_2)(1)=\alpha(x_1-x_2)(\eta). \end{aligned}$$

It follows that

$$\begin{aligned} \bigl\|x_1''-x_2''\bigr\|_2 &= \bigl\|f\bigl(t,x_1(t),x_1'(t)\bigr)-f\bigl(t,y_1(t),y_1'(t)\bigr)\bigr\|_2\\ &\leqslant c\|x_1-x_2\|_2+\bigl\|x_1'-x_2'\bigr\|_2\\ &\leqslant \frac{2}{\pi}\left(\frac{2}{\pi}c+d\right)\bigl\|x_1''-x_2''\bigr\|_2. \end{aligned}$$

Hence, we get that $\|x_1''-x_2''\|_2=0$. It now follows from the inequalities

$$\|x_1-x_2\|_2\leqslant\frac{2}{\pi}\bigl\|x_1'-x_2'\bigr\|_2\leqslant\frac{4}{\pi^2}\bigl\|x_1''-x_2''\bigr\|_2=0,$$

that $x_1(t)=x_2(t)$ for a.e. $t\in[0,1]$ and hence for every $t\in[0,1]$ because of the continuity of $x_1(t)$ and $x_2(t)$ on $[0,1]$. This completes the proof of the theorem in the case when $\alpha\leqslant 1$. The proof for the case $1<\alpha<1/\eta$ is similar. □

THEOREM 3.15. *Let* $f:[0,1]\times\mathbb{R}^2\to\mathbb{R}$ *be as in Theorem* 3.14. *Then for any given* $e(t)$ *in* $L^2(0,1)$, *the* m*-point BVP* (3.26)–(3.27) *has exactly one solution in* $C^1[0,1]$ *provided*

$$\begin{cases} \|p\|_1+\|q\|_1<1, & \text{if } \alpha\leqslant 1,\\ \|p\|_1+\|q\|_1<\dfrac{1-\alpha\xi_{m-2}}{\alpha(1-\xi_1)}, & \text{if } 1<\alpha<1/\eta. \end{cases}$$

We now give a theorem which allows f to have nonlinear growth. We do this by imposing a decomposition condition for f. We need the following simple lemma.

LEMMA 3.16. *Let* $x\in C^1[0,1]$ *satisfy* $x(0)=0, x(1)=\alpha x(\eta)$, *where* $\eta\in(0,1)$, *and* $\alpha>1$, $\alpha\neq 1/\eta$, *then there exist* ζ *and* $C_0\in(0,1)$ *such that* $x'(\zeta)=C_0x(1)$.

PROOF. If $\alpha\eta>1$, let $C_0=1/(\alpha\eta)$. There exists $\zeta\in(0,1)$ with

$$x'(\zeta)=\frac{x(\eta)-x(0)}{\eta}=C_0x(1).$$

If $\alpha\eta<1$, let $C_0=\frac{\alpha-1}{\alpha(1-\eta)}$. There exists $\zeta\in(\eta,1)$ with

$$x'(\zeta)=\frac{x(1)-x(\eta)}{1-\eta}=\frac{\alpha-1}{\alpha(1-\eta)}x(\eta)=C_0x(1). \qquad\square$$

THEOREM 3.17. *Assume that* $f:[0,1]\times\mathbb{R}^2\to\mathbb{R}$ *is continuous and has the decomposition*

$$f(t,x,p)=g(t,x,p)+h(t,x,p)$$

such that

(1) $pg(t,x,p)\leqslant 0$ *for all* $(t,x,p)\in[0,1]\times\mathbb{R}^2$;

(2) $h(t,x,p)|\leqslant a(t)|x|+b(t)|p|+u(t)|x|^r+v(t)|p|^k+c(t)$ *for all* $(t,x,p)\in[0,1]\times\mathbb{R}^2$ *where* a,b,u,v *are in* $L^1[0,1]$ *and* $0\leqslant r,k<1$.

Then, for $\alpha\neq 1/\eta$, *there exists a solution* $x\in C^1[0,1]$ *to BVP* (3.26), (3.30) *provided that*

$$\begin{cases} \|a\|_1+\|b\|_1<\dfrac{1}{2}, & \text{if } \alpha\leqslant 1,\\ \|a\|_1+\|b\|_1<\dfrac{1}{2}\left(1-\dfrac{(\alpha-1)^2}{\alpha^2(1-\eta)^2}\right), & \text{if } 1<\alpha<\dfrac{1}{\eta},\\ \|a\|_1+\|b\|_1<\dfrac{1}{2}\left(1-\dfrac{1}{\alpha^2\eta^2}\right), & \text{if } \dfrac{1}{\eta}<\alpha. \end{cases}$$

PROOF. By the same argument as in the proof of Theorem 3.12, it suffices to show that all possible solutions of the following family of equations (3.33)–(3.34) is bounded in $C^1[0,1]$ by a constant independent of $\lambda\in[0,1]$.

Suppose that x is a solution of (3.33) and let ζ be as in Lemma 3.16 and write $C = \|c\|_1 + \|e\|_1$. Multiplying both sides of Eq. (3.33) with x' and integrating, we obtain

$$\begin{aligned}\frac{1}{2}x'^2(t) &\leqslant \frac{1}{2}x'^2(\zeta) + \|x'\|_\infty\big(\|a\|_1\|x\|_\infty + \|b\|_1\|x'\|_\infty \\ &\quad + \|u\|_1\|x\|_\infty^r + \|v\|_1\|x'\|_\infty^k + C\big) \\ &= \frac{1}{2}C_0^2 x'^2(1) + \|x'\|_\infty\big(\|a\|_1\|x\|_\infty + \|b\|_1\|x'\|_\infty \\ &\quad + \|u\|_1\|x\|_\infty^r + \|v\|_1\|x'\|_\infty^k + C\big).\end{aligned}$$

Since $\|x\|_\infty \leqslant \|x'\|_\infty$ and by assumption

$$\|a\|_1 + \|b\|_1 < \frac{1}{2}\big(1 - C_0^2\big).$$

If $\|x'\|_\infty \neq 0$, we have

$$\left(\frac{1}{2}\big(1 - C_0^2\big) - \big(\|a\|_1 + \|b\|_1\big)\right)\|x'\|_\infty \leqslant \|u\|_1\|x\|_\infty^r + \|v\|_1\|x'\|_\infty^k + C.$$

This implies that $\|x'\|_\infty$ is bounded since $0 \leqslant r, k < 1$, that is, there is $M > 0$ such that $\|x\|_\infty \leqslant \|x'\|_\infty \leqslant M$. This completes the proof. □

Theorem 3.17 is taken over from Feng and Webb [15] and is more general than Theorem 3.12, since the assumptions of Theorem 3.12 are special cases of Theorem 3.17, when $g(t, x, p) \equiv 0$, $u(t) \equiv 0$ and $v(t) \equiv 0$. But in Theorem 3.12 we need $\|a\|_1 + \|b\|_1 < 1$ and in Theorem 3.17 in these special cases we need $\|a\|_1 + \|b\|_1 < 1/2$. In [15] also interesting examples are given to compare their results with other existence results.

We now give existence results for the BVPs (3.26), (3.31) and (3.26), (3.32). By using the same argument as in Theorem 3.12 we can prove the following existence results (see [32,34]).

THEOREM 3.18. *Let $f : [0, 1] \times \mathbb{R}^2 \to \mathbb{R}$ be a function satisfying Carathéodory's conditions. Assume that* (3.12) *holds. Also let $\alpha \in \mathbb{R}$, and $\eta \in (0, 1)$ be given. Then the BVP* (3.26), (3.31) *has at least one solution in $C^1[0, 1]$ provided*

$$\begin{cases} \|p\|_1 + \|q\|_1 < 1, & \textit{if}\ \alpha \leqslant 0, \\ \left(1 + \max\left\{\dfrac{\alpha(1-\eta)}{|\alpha - 1|}, \dfrac{1-\eta}{|\alpha - 1|}\right\}\right)\|p\|_1 + \|q\|_1 < 1, & \textit{if}\ 0 < \alpha \neq 1. \end{cases}$$

In Theorem 3.18 if p, q, r are in $L^2(0,1)$ then the BVP (3.26), (3.31) has at least one solution in $C^1[0,1]$ provided

$$\begin{cases} \dfrac{2}{\pi}\left(\dfrac{2}{\pi}\|p\|_2 + \|q\|_2\right) < 1, & \text{if } \alpha \leqslant 0, \\ \left(\dfrac{\sqrt{2}}{\pi} + \max\left\{\dfrac{\alpha(1-\eta)}{|\alpha-1|}, \dfrac{1-\eta}{|\alpha-1|}\right\}\right)\|p\|_1 + \dfrac{2}{\pi}\|q\|_1 < 1, & \text{if } 0 < \alpha \neq 1. \end{cases}$$

THEOREM 3.19. *Let $f : [0,1] \times \mathbb{R}^2 \to \mathbb{R}$ be a function satisfying Carathéodory's conditions. Assume that* (3.12) *holds. Also let $\alpha \in \mathbb{R}$, $\alpha \neq 1$ and $\eta \in (0,1)$ be given. Then the BVP* (3.26), (3.32) *has at least one solution in $C^1[0,1]$ provided*

$$\left(\max\left\{\frac{1+|\alpha-1|}{|\alpha-1|}, \frac{|\alpha|+|\alpha-1|}{|\alpha-1|}\right\}\right)\left(\|p\|_1 + \|q\|_1\right) < 1.$$

As in Theorem 3.13 we prove existence results for the m-point BVPs (3.26), (3.28) and (3.29), (3.31), by using the a priori bounds obtained for the BVPs (3.26), (3.31) and (3.26), (3.32).

3.6. *Results at resonance*

In the following we shall give existence results for BVP (3.26), (3.30) when $\alpha\eta = 1$. In this case, the linear operator L is noninvertible and the Leray–Schauder continuation theorem cannot be used. We shall apply the continuation theorem of Mawhin [82]. For the convenience of the reader, we recall this theorem.

Let X and Z be Banach spaces and $L : D(L) \subset X \to Z$ be a linear operator which is Fredholm of index zero (that is $\operatorname{im}(L)$ (the image of L) is closed in Z, and $\ker(L)$ (the kernel of L) and $Z/\operatorname{im}(L)$ (the cokernel of L) are finite-dimensional with equal dimension). Let $P : X \to \ker(L)$ and $Q : Z \to Z_1$, where $X = \ker(L) \oplus X_1$ and $Z = \operatorname{im}(L) \oplus Z_1$, be continuous projections. Let L_1 denote L restricted to $D(L) \cap X_1$, an invertible operator into $\operatorname{im}(L)$, and write $K = L_1^{-1}$. Let Ω be a bounded, open subset of X such that $D(L) \cap \Omega \neq \emptyset$ and let $N : \overline{\Omega} \to Z$ be an L-compact mapping, that is, the maps $QN : \overline{\Omega} \to Z$ and $K(I-Q)N : \overline{\Omega} \to X$ are compact.

THEOREM 3.20. *Let L be Fredholm of index zero and let N be L-compact on $\overline{\Omega}$. Assume that the following conditions are satisfied.*

(1) $Lx + \lambda Nx \neq 0$ *for each* $(x, \lambda) \in [D(L) \setminus \ker L \cap \partial\Omega] \times (0,1)$.
(2) $Nx \notin \operatorname{im}(L)$ *for each* $x \in \ker(L) \cap \partial\Omega$.
(3) $\deg(QN|_{\ker L}, \Omega \cap \ker(L), 0) \neq 0$, *where $Q : Z \to Z$ is a continuous projection as above.*

Then the equation $Lx + Nx = 0$ has at least one solution in $D(L) \cap \overline{\Omega}$.

The following existence theorems hold.

THEOREM 3.21. *Let* $f:[0,1]\times\mathbb{R}^2\to\mathbb{R}$ *be a continuous function. Assume that*:

(1) *There exist functions* p,q,r *in* $L^1[0,1]$ *such that*

$$\bigl|f(t,u,v)\bigr|\leqslant p(t)|u|+q(t)|v|+r(t),\quad \text{for } t\in[0,1] \text{ and } (u,v)\in\mathbb{R}^2.$$

(2) *There exists* $N>0$ *such that for* $v\in\mathbb{R}$ *with* $|v|>N$, *one has*

$$\bigl|f(t,u,v)\bigr|\geqslant -l|u|+n|v|-M\quad \text{for } t\in[0,1],\ u\in\mathbb{R}$$

where $n>l\geqslant 0$, $M\geqslant 0$.

(3) *There exists* $R>0$ *such that for* $|v|>R$ *one has either*

$$vf(t,vt,v)\leqslant 0\quad \text{for } t\in[0,1]$$

or else

$$vf(t,vt,v)\geqslant 0\quad \text{for } t\in[0,1].$$

Then, for every continuous function e, *the BVP* (3.26), (3.30) *with* $\alpha\eta=1$ *has at least one solution in* $C^1[0,1]$ *provided that*

$$2\bigl(\|p\|_1+\|q\|_1\bigr)+\frac{l}{n}<1.$$

We give the proof via several lemmas. We now let L be the linear operator from $D(L)\subset X\to Z=L^1(0,1)$ defined by

$$D(L)=\bigl\{x\in W^{2,1}(0,1):\ x(0)=0, x(1)=x(\eta)/\eta\bigr\}$$

and for $x\in D(L)$, $Lx=x''$. Let $X_1=\{x\in X:\ x(0)=0\}$.

LEMMA 3.22. *Suppose L is as above. Then* $L:D(L)\subset X\to Z$ *is Fredholm of index zero. Furthermore, the linear operator* $K:\operatorname{im}(L)\to D(L)\cap X_1$ *defined by*

$$(Ky)(t)=\int_0^t\int_0^\tau y(s)\,\mathrm{d}s\,\mathrm{d}\tau,\qquad y\in\operatorname{im}(L)$$

is such that $K=L_P^{-1}$, *where* $L_P=L|_{D(L)\cap X_1}$. *Also* $\|Ky\|\leqslant\|y\|_1$ *for all* $y\in\operatorname{im}(L)$.

PROOF. It is easy to see that $\ker(L)=\{ct:\ c\in\mathbb{R}\}$. We show that

$$\operatorname{im}(L)=\left\{y\in L^1[0,1]:\ \int_0^1 Y(t)\,\mathrm{d}t=\int_0^1 Y(\eta t)\,\mathrm{d}t,\ \text{where } Y(t)=\int_0^t y(s)\,\mathrm{d}s\right\}.$$

In fact, for $y \in \operatorname{im}(L)$, there is $x \in D(L)$ with $y(t) = x''(t)$. Therefore

$$\int_0^1 Y(t)\,\mathrm{d}t = \int_0^1 \big[x'(t) - x'(0)\big]\,\mathrm{d}t = x(1) - x'(0),$$

and

$$\int_0^1 Y(\eta t)\,\mathrm{d}t = \int_0^1 \big[x'(\eta t) - x'(0)\big]\,\mathrm{d}t = x(\eta)/\eta - x'(0).$$

Since $x(1) = \frac{1}{\eta}x(\eta)$, we have $\int_0^1 Y(t)\,\mathrm{d}t = \int_0^1 Y(\eta t)\,\mathrm{d}t$. On the other hand, suppose $y \in L^1[0,1]$ is such that $\int_0^1 Y(t)\,\mathrm{d}t = \int_0^1 Y(\eta t)\,\mathrm{d}t$. Let $x(t) = \int_0^t Y(s)\,\mathrm{d}s$, then $x \in D(L)$ and $x''(t) = y(t)$.

For $y \in L^1[0,1]$, let

$$Qy = \frac{2}{1-\eta}\int_0^1 \int_{\eta t}^t y(s)\,\mathrm{d}s\,\mathrm{d}t,$$

and let $y_1(t) = y(t) - Qy$. Then $Y_1(t) = \int_0^t y(s)\,\mathrm{d}s - (Qy)(t)$, and writing Qy in the form

$$Qy = \frac{2}{1-\eta}\left\{\int_0^1 \int_0^t y(s)\,\mathrm{d}s\,\mathrm{d}t - \int_0^1 \int_0^{\eta t} y(s)\,\mathrm{d}s\,\mathrm{d}t\right\},$$

we see that

$$\int_0^1 \int_0^t y(s)\,\mathrm{d}s\,\mathrm{d}t - \frac{Qy}{2} = \int_0^1 \int_0^{\eta t} y(s)\,\mathrm{d}s\,\mathrm{d}t - \eta\frac{Qy}{2},$$

that is

$$\int_0^1 Y_1(t)\,\mathrm{d}t = \int_0^1 Y_1(\eta t)\,\mathrm{d}t.$$

This shows that $y_1 \in \operatorname{im}(L)$. Hence $Z = \operatorname{im}(L) + \mathbb{R}$. Since $\operatorname{im}(L) \cap \mathbb{R} = \{0\}$, we have $Z = \operatorname{im}(L) \oplus \mathbb{R}$ and therefore L is Fredholm of index zero.

Now we define a projection from X onto $\ker(L)$ by setting $(Px)(t) = x'(0)t$ and let $X_1 = \{x \in X, x'(0) = 0\}$. Then, for $x \in D(L) \cap X_1$, we have

$$(KL_Px)(t) = Kx''(t) = \int_0^t \int_0^\tau x''(s)\,\mathrm{d}s\,\mathrm{d}\tau = \int_0^t \big(x'(\tau) - x'(0)\big)\,\mathrm{d}\tau = x(t),$$

and for $y \in \operatorname{im}(L)$, we have

$$(L_PKy)(t) = \left(\int_0^t \int_0^\tau y(s)\,\mathrm{d}s\,\mathrm{d}\tau\right)'' = y(t).$$

This shows that $K = L_P^{-1}$. Also we have

$$\left\|(Ky)(t)\right\|_\infty \leqslant \int_0^1 \int_0^1 \left|y(s)\right| \mathrm{d}s \, \mathrm{d}\tau \leqslant \left\|y(t)\right\|_1,$$

and

$$(Ky)'(t) = \int_0^t y(s)\,\mathrm{d}s, \quad \text{so} \quad \left\|(Ky)'(t)\right\|_\infty \leqslant \left\|y(t)\right\|_1,$$

and hence $\|Ky\| \leqslant \|y\|_1$ which completes the proof. □

LEMMA 3.23. *Let $U_1 = \{x \in D(L) \setminus \ker(L), Lx + \lambda Nx = 0$ for some $\lambda \in [0,1]\}$. Then U_1 is a bounded subset of X.*

PROOF. Suppose that $x \in U_1$, and $Lx = -\lambda Nx$, then $\lambda \neq 0$ and $QNx = 0$. Therefore

$$\int_0^1 \int_{\eta\tau}^{\tau} \left(f\left(t, x(t), x'(t)\right) + e(t)\right) \mathrm{d}t \, \mathrm{d}\tau = 0,$$

and hence there exists $\gamma \in (0,1)$ such that

$$\left|f\left(\gamma, x(\gamma), x'(\gamma)\right)\right| = \left|e(\gamma)\right| \leqslant \left\|e(t)\right\|_\infty.$$

Also for $x \in D(L) \setminus \ker(L)$, by Lemma 3.22 and condition (1)

$$\begin{aligned}\left\|(I-P)x\right\| &= \left\|KL(I-P)x\right\| \leqslant \left\|L(I-P)x\right\|_1 = \left\|L(x)\right\|_1 \\ &\leqslant \left\|N(x)\right\|_1 \leqslant \|p\|_1\|x\|_\infty + \|q\|_1\|x'\|_\infty + \|r\|_1 + \|e\|_1.\end{aligned}$$

If for some $t_0 \in [0,1]$, $|x'(t_0)| \leqslant N$ then we have

$$\left|x'(0)\right| = \left|x'(t_0) - \int_0^{t_0} x''(t)\,\mathrm{d}t\right| \leqslant N + \|x''\|_1.$$

Otherwise, if $|x'(t)| > N$ for all t, from condition (2) we obtain

$$\left|x'(\gamma)\right| \leqslant \frac{\|e\|_\infty + M}{n} + \frac{l}{n}\|x\|_\infty,$$

so that

$$\left|x'(0)\right| = \left|x'(\gamma) - \int_0^{\gamma} x''(t)\,\mathrm{d}t\right| \leqslant \frac{\|e\|_\infty + M}{n} + \frac{l}{n}\|x\|_\infty + \|x''\|_1.$$

Therefore we have in either case

$$\big\|P(x)\big\| = \big|x'(0)\big| \leqslant \max\left\{\frac{\|e\|_\infty + M}{n}, N\right\} + \frac{l}{n}\|x\|_\infty + \|x''\|_1.$$

Writing $x(t) = \int_0^t x'(s)\,\mathrm{d}s$, we obtain

$$\|x\|_\infty \leqslant \|x'\|_1 \leqslant \|x'\|_\infty.$$

Therefore

$$\begin{aligned}\|x'\|_\infty &\leqslant \|x\| \leqslant \big\|(I-P)(x)\big\| + \|Px\| \\ &\leqslant \left(\|p\|_1 + \|q\|_1 + \frac{l}{n}\right)\|x'\|_\infty + \|x''\|_1 + C,\end{aligned}$$

where $C = \|r\|_1 + \max\{\|e\|_\infty + M/n, N\}$. Let $C_1 = 1 - [\|p\|_1 + \|q\|_1 + \frac{l}{n}]$, so that $C_1 > 0$. Then we can write

$$\|x'\|_\infty \leqslant \frac{1}{C_1}\|x''\|_1 + \frac{C}{C_1},$$

and then

$$\begin{aligned}\|x''\|_1 = \big\|L(x)\big\|_1 &\leqslant \|Nx\|_1 \leqslant \|p\|_1\|x\|_\infty + \|q\|_1\|x'\|_\infty + \|r\|_1 + \|e\|_1 \\ &\leqslant \big(\|p\|_1 + \|q\|_1\big)\|x'\|_\infty + \|r\|_1 + \|e\|_1 \\ &\leqslant \frac{\|p\|_1 + \|q\|_1}{C_1}\|x''\|_1 + C_2,\end{aligned}$$

where $C_2 = \frac{\|p\|_1 + \|q\|_1}{C_1} + \|r\|_1 + \|e\|_1$. If $C_3 = \frac{\|p\|_1 + \|q\|_1}{C_1}$ then $C_3 < 1$ and hence

$$\|x\|_\infty \leqslant \|x'\|_\infty \leqslant \frac{C_2}{C_1(1-C_3)} + \frac{C}{C_1},$$

which proves that U_1 is bounded. □

LEMMA 3.24. *The set* $U_2 := \{x \in \ker(L)\colon\ N(x) \in \operatorname{im}(L)\}$ *is bounded.*

PROOF. Suppose that $x \in U_2$ so that $x(t) = ct$, where c is a constant. Since $QNx = 0$, we have

$$\int_0^1 \int_{\eta\tau}^{\tau} f(t, ct, c)\,\mathrm{d}t\,\mathrm{d}\tau = -\int_0^1 \int_{\eta\tau}^{\tau} e(t)\,\mathrm{d}t\,\mathrm{d}\tau.$$

Therefore there exists $\xi \in (0,1)$ such that $|f(\xi, c\xi, c)| \leqslant |e(\xi)| \leqslant \|e\|_\infty$. It follows that

$$|c| \leqslant \max\left\{N, \frac{M + \|e\|_\infty}{n-l}\right\}.$$

For, if $|c| > N$, then by condition (2) we obtain $\|e\|_\infty \geqslant -l|c\xi| + n|c| - M$ and hence $|c| \leqslant (M + \|e\|_\infty)/(n-l)$. Thus U_2 is bounded. □

LEMMA 3.25. *If in condition* (3) *we assume that there exists* $R > 0$ *such that for all* $|v| > R$, $vf(t, vt, v) \leqslant 0$, *for* $t \in [0,1]$, *then the set*

$$U_3 := \bigl\{x \in \ker(L)\colon\ H(x,\lambda) = \lambda Jx + (1-\lambda)QNx = 0,\ \lambda \in [0,1]\bigr\},$$

is bounded, where $J : \ker(L) \to Z_0$, *is the linear isomorphism given by* $J(ct) = c$.

PROOF. Assume that $x_n(t) - c_n t \in U_3$ and $\|c_n t\| = |c_n| \to \infty$ as $n \to \infty$. Then there exists $\lambda_n \in [0,1]$ such that

$$\lambda_n c_n + (1-\lambda_n)(QN)(c_n t) = 0.$$

$\{\lambda_n\}$ has a convergent subsequence, for simplicity we write $\lambda_n \to \lambda_0$. We show that $\lambda_0 \neq 1$. Indeed, otherwise we have

$$\lambda_n = -(1-\lambda_n)\frac{(QN)c_n t}{c_n},$$

and as previously we find that

$$(1-\lambda_n)\frac{\|(QN)c_n t\|}{|c_n|} \to 0 \quad (n \to \infty),$$

contradicting $\lambda_n \to 1$. Hence for n large enough, $1 - \lambda_n \neq 0$, and therefore

$$\frac{\lambda_n}{1-\lambda_n} c_n = Q\bigl(f(t, c_n t, c_n) + e(t)\bigr),$$

and so

$$\frac{\lambda_n}{1-\lambda_n} = \frac{2}{1-\eta}\int_0^1 \int_{\eta\tau}^{\tau} \frac{f(s, c_n s, c_n)}{c_n}\,\mathrm{d}s\,\mathrm{d}\tau + \frac{2}{c_n(1-\eta)}\int_0^1 \int_{\eta\tau}^{\tau} e(s)\,\mathrm{d}s\,\mathrm{d}\tau.$$

Since $|c_n| \to \infty$, we may assume that $|c_n| > \max\{N, R\}$. Then for large enough n we have

$$\left|\frac{f(s, c_n s, c_n)}{c_n}\right| \geqslant n - l - \frac{M}{|c_n|} \geqslant \frac{n-l}{2}.$$

By our assumption $c_n f(t, c_n t, c_n) \leqslant 0$ this yield $f(t, c_n t, c_n)/c_n \leqslant -(n-l)/2$. Hence, by Fatou's lemma,

$$
\begin{aligned}
&\limsup_{n\to\infty}\left\{\int_0^1\int_{\eta\tau}^{\tau}\frac{f(s, c_n s, c_n)}{c_n}\,\mathrm{d}s\,\mathrm{d}\tau+\frac{1}{c_n}\int_0^1\int_{\eta\tau}^{\tau}e(s)\,\mathrm{d}s\,\mathrm{d}\tau\right\}\\
&\quad\leqslant \limsup_{n\to\infty}\int_0^1\int_{\eta\tau}^{\tau}\frac{f(s, c_n s, c_n)}{c_n}\,\mathrm{d}s\,\mathrm{d}\tau\\
&\quad\leqslant \int_0^1\int_{\eta\tau}^{\tau}\limsup_{n\to\infty}\frac{f(s, c_n s, c_n)}{c_n}\,\mathrm{d}s\,\mathrm{d}\tau\\
&\quad\leqslant -\frac{(n-l)(1-\eta)}{4}.
\end{aligned}
$$

This is a contradiction with $\lambda_n/(1-\lambda_n) \geqslant 0$. Thus U_3 is bounded. □

PROOF OF THEOREM 3.21. Firstly, by Arzelá–Ascoli theorem, it can be shown that the linear operator $K : \mathrm{im}(L) \to D(L) \cap X_1$ in Lemma 3.22 is compact operator, so N is L-compact. Let Ω be a bounded open set containing $\overline{\bigcup_{i=1}^{3} U_i}$. Then by the above lemmas the conditions of Theorem 3.20 are satisfied and therefore $Lx + Nx = 0$ has at least one solution in $D(L) \cap \overline{\Omega}$ so that the BVP (3.26), (3.30) with $\alpha\eta = 1$ has at least one solution. □

THEOREM 3.26. *Assume that* $f : [0, 1] \times \mathbb{R}^2 \to \mathbb{R}$ *is continuous and has the decomposition*

$$f(t, x, p) = g(t, x, p) + h(t, x, p).$$

Assume that

(1) *There exists* $M_1 > 0$ *such that for* $x \in D(L) := \{x \in W^{2,1}(0, 1)\colon\ x(0) = 0,\ x(1) = \frac{1}{\eta}x(\eta)\}$, *if* $|x'(t)| > M_1$ *for all* $t \in [0, 1]$, *then*

$$\int_0^1\int_{\eta s}^{s}\bigl(f\bigl(t, x(t), x'(t)\bigr) + e(t)\bigr)\,\mathrm{d}t\,\mathrm{d}s \neq 0;$$

(2) *There exists* $M_2 > 0$, *such that for all* $v \in \mathbb{R}$ *with* $|v| > M_2$ *one has either*

$$v\bigl(f(t, vt, v) + e(t)\bigr) \geqslant 0 \quad \textit{for } t \in [0, 1],$$

or

$$v\bigl(f(t, vt, v) + e(t)\bigr) \leqslant 0 \quad \textit{for } t \in [0, 1];$$

(3) $pg(t, x, p) \leqslant 0$ *for all* $(t, x, p) \in [0, 1] \times [-M, M] \times \mathbb{R}$;

(4) $|h(t,x,p)| \leqslant a(t)|x| + b(t)|p| + u(t)|x|^r + v(t)|p|^k + c(t)$ *for* $(t,x,p) \in [0,1] \times [-M,M] \times \mathbb{R}$ *where* a, b, u, v *are in* $L^1[0,1]$ *and* $0 \leqslant r, k < 1$.

Then, the BVP (3.26), (3.30) *with* $\alpha\eta = 1$ *has at least one solution in* $C^1[0,1]$ *provided that*

$$\|a\|_1 + \|b\|_1 < \frac{1}{2}.$$

Theorem 3.21 is taken over from [16]. For the proof of Theorem 3.26 we refer to [15]. Other results are given by Gupta in [27,34]. In [16] is also proved the following uniqueness result.

THEOREM 3.27. *Suppose that the conditions* (1) *and* (2) *in Theorem* 3.21 *are replaced by the following conditions respectively*:

(1) *There exist functions* p, q *in* $L^1[0,1]$ *such that*

$$\bigl|f(t,u_1,v_1) - f(t,u_2,v_2)\bigr| \leqslant p(t)|u_1 - u_2| + q(t)|v_1 - v_2|$$

for $t \in [0,1]$ *and* $(u_1, v_1), (u_2, v_2) \in \mathbb{R}^2$.

(2) *There exists* $n > l \geqslant 0$ *such that*

$$\bigl|f(t,u_1,v_1) - f(t,u_2,v_2)\bigr| \geqslant -l|u_1 - u_2| + n|v_1 - v_2|$$

for $t \in [0,1]$, $(u_1, v_1), (u_2, v_2) \in \mathbb{R}^2$.

Then the BVP (3.26), (3.30) *with* $\alpha\eta = 1$ *has exactly one solution in* $C^1[0,1]$ *provided that*

$$2\bigl(\|p\|_1 + \|q\|_1\bigr) + \frac{l}{n} < 1.$$

3.7. *m-point boundary value problems reduced to four-point boundary value problems*

Let $f : [0,1] \times \mathbb{R}^2 \to \mathbb{R}$ be either a continuous or a Carathéodory's function and $e : [0,1] \to \mathbb{R}$ be a function in $L^1[0,1]$, $c_i, a_j \in \mathbb{R}$, with all of the c_i's, and all of a_j's, having the same sign, $\xi_i, \tau_j \in (0,1)$, $i = 1, 2, \dots, m-2$, $j = 1, 2, \dots, n-2$, $0 < \xi_1 < \xi_2 < \cdots < \xi_{m-2} < 1$, $0 < \tau_1 < \tau_2 < \cdots < \tau_{n-2} < 1$.

Consider the following second-order ordinary differential equation

$$x''(t) = f\bigl(t, x(t), x'(t)\bigr) + e(t), \quad t \in (0,1) \tag{3.38}$$

subject to one of the following boundary conditions

$$x(0) = \sum_{i=1}^{m-2} c_i x'(\xi_i), \qquad x(1) = \sum_{j=1}^{n-2} a_j x(\tau_j), \tag{3.39}$$

$$x(0)=\sum_{i=1}^{m-2} c_i x'(\xi_i), \qquad x'(1)=\sum_{j=1}^{n-2} a_i x'(\tau_j), \tag{3.40}$$

$$x(0)=\sum_{i=1}^{m-2} c_i x'(\xi_i), \qquad x(1)=\sum_{j=1}^{n-2} a_i x(\tau_j), \tag{3.41}$$

$$x(0)=\sum_{i=1}^{m-2} c_i x(\xi_i), \qquad x'(1)=\sum_{j=1}^{n-2} a_i x'(\tau_j). \tag{3.42}$$

It is well known that if a function $x \in C^1$ satisfies one of the boundary conditions (3.39)–(3.42) and c_i, a_j, $i = 1, 2, \dots, m-2$, $j = 1, 2, \dots, n-2$ are as above, then there exist $\zeta \in [\xi_1, \xi_{m-2}]$, $\eta \in [\tau_1, \tau_{n-2}]$ such that

$$x(0)=\gamma x'(\zeta), \qquad x(1)=\alpha x(\eta), \tag{3.43}$$

$$x(0)=\gamma x'(\zeta), \qquad x'(1)=\alpha x'(\eta), \tag{3.44}$$

$$x(0)=\gamma x(\zeta), \qquad x(1)=\alpha x(\eta), \tag{3.45}$$

$$x(0)=\gamma x(\zeta), \qquad x'(1)=\alpha x'(\eta), \tag{3.46}$$

respectively with $\gamma = \sum_{i=1}^{m-2} c_i$, $\alpha = \sum_{j=1}^{n-2} a_j$.

As in the case of m-point BVPs which are reduced to three-point BVPs, we shall prove an existence result the BVP (3.38)–(3.39), proving first an existence result for the BVP (3.38), (3.43), and using the a priori bounds obtained for this problem for the BVP (3.38)–(3.39). In the next lemma we obtain the needed a priori bounds, which are independent of ζ and η, for the BVP (3.38), (3.43).

LEMMA 3.28. *Let $\zeta, \eta \in (0, 1)$ is given and $x(t) \in W^{2,1}(0, 1)$ be such that $x(0) = \gamma x'(\zeta)$, $x(1) = \alpha x(\eta)$. Then*

$$\|x\|_\infty \leqslant A\|x'\|_\infty, \qquad \|x'\|_\infty \leqslant B\|x''\|_1$$

where

$$A = \begin{cases} 1, & \text{if } \alpha \leqslant 0, \\ L, & \text{if } \alpha > 0, \alpha \neq 1, \\ 1 + |\gamma|, & \text{if } \alpha = 1 \end{cases}$$

and

$$B = \begin{cases} 1, & \text{if } \alpha \leqslant 0, \gamma = 0, \\ \dfrac{1}{1-Q}, & \text{if } \alpha \leqslant 0, \gamma \neq 0, \\ \dfrac{1}{1-S}, & \text{if } \alpha > 0, \alpha \neq 1, \\ 1, & \text{if } \alpha = 1, \end{cases}$$

where for $\alpha > 0, \alpha \neq 1$,

$$\begin{cases} M = \min\left\{\alpha, \dfrac{1}{\alpha}\right\} < 1, \\ L = \min\left\{\dfrac{1}{1-M}, 1 + \dfrac{1-\eta}{|1-\alpha|}, 1 + \dfrac{|\alpha|(1-\eta)}{|1-\alpha|}, 1 + |\gamma|\right\}, \\ S = \min\left\{\dfrac{|1-\alpha|}{1-\eta}L, \dfrac{|1-\alpha|}{\alpha(1-\eta)}L, \dfrac{1}{|\gamma|}L\right\} \end{cases}$$

for $\alpha < 0$,

$$Q = \min\left\{\frac{1-\alpha}{1-\eta}, \frac{1-\alpha}{|\alpha|(1-\eta)}, \frac{1}{|\gamma|}\right\}$$

and for $\alpha = 0$, $Q = \frac{1}{|\gamma|}$ *provided* $Q < 1$ *and* $S < 1$.

PROOF. We consider the following cases:

Case 1: $\alpha \leqslant 0$. In this case $x(1)x(\eta) \leqslant 0$ and accordingly there exists a $\theta \in [\eta, 1]$ such that $x(\theta) = 0$. Hence it follows that $\|x\|_\infty \leqslant \|x'\|_\infty$. Also if $\gamma = 0$, we have from $x(0) = 0$ and $x(\theta) = 0$ that there exists a $z \in (0, \theta)$ such that $x'(z) = 0$. Accordingly, we get that $\|x'\|_\infty \leqslant \|x''\|_1$. Suppose, now, that $\alpha < 0$ and $\gamma \neq 0$. Next we see from Mean Value Theorem there exists $\omega \in (\eta, 1)$ such that

$$(\alpha - 1)x(\eta) = x(1) - x(\eta) = (1 - \eta)x'(\omega)$$

and hence

$$x(\eta) = \frac{1-\eta}{\alpha - 1}x'(\omega).$$

Also, since $x(1) = \alpha x(\eta)$ we get

$$x(1) = \frac{\alpha(1-\eta)}{\alpha - 1}x'(\omega).$$

From the relations

$$x'(t) = x'(\omega) + \int_\omega^t x''(s)\,\mathrm{d}s = \frac{\alpha - 1}{1 - \eta}x(\eta) + \int_\omega^t x''(s)\,\mathrm{d}s,$$
$$x'(t) = x'(\omega) + \int_\omega^t x''(s)\,\mathrm{d}s = \frac{\alpha - 1}{\alpha(1 - \eta)}x(1) + \int_\omega^t x''(s)\,\mathrm{d}s$$

and

$$x'(t) = x'(\zeta) + \int_0^t x''(s)\,\mathrm{d}s = \frac{1}{\gamma}x(0) + \int_0^t x''(s)\,\mathrm{d}s$$

then follows that

$$\|x'\|_\infty \leqslant \frac{1}{1-Q}\|x''\|_1,$$

where $Q=\min\{\frac{1-\alpha}{1-\eta}, \frac{1-\alpha}{|\alpha|(1-\eta)}, \frac{1}{|\gamma|}\}$ if $Q<1$. Finally, for $\alpha=0$, $\gamma\neq 0$ it is easy to see that $Q=\frac{1}{|\gamma|}$ since we require that $Q<1$ and $\frac{1}{1-\eta}>1$.

Case 2: $\alpha>0, \alpha\neq 1$. We first consider the relations

$$x(t)=x(1)+\int_1^t x'(s)\,\mathrm{d}s=\alpha x(\eta)+\int_1^t x'(s)\,\mathrm{d}s$$

and

$$x(t)=x(\eta)+\int_\eta^t x'(s)\,\mathrm{d}s=\frac{1}{\alpha}x(1)+\int_\eta^t x'(s)\,\mathrm{d}s.$$

Since, now, $M=\min\{\alpha, \frac{1}{\alpha}\}<1$, we get from the above relations that

$$\|x\|_\infty \leqslant \frac{1}{1-M}\|x'\|_\infty.$$

Next, we get the relations

$$x(t)=x(1)+\int_1^t x'(s)\,\mathrm{d}s=\frac{\alpha(1-\eta)}{\alpha-1}x'(\omega)+\int_1^t x'(s)\,\mathrm{d}s$$

and

$$x(t)=x(\eta)+\int_\eta^t x'(s)\,\mathrm{d}s=\frac{1-\eta}{\alpha-1}x'(\omega)+\int_\eta^t x'(s)\,\mathrm{d}s.$$

From these relations and

$$x(t)=x(0)+\int_0^t x'(s)\,\mathrm{d}s=\gamma x'(\zeta)+\int_0^t x'(s)\,\mathrm{d}s$$

it is immediate that

$$\|x\|_\infty \leqslant L\|x'\|_\infty,$$

where $L=\min\{\frac{1}{1-M}, 1+\frac{1-\eta}{|\alpha-1|}, 1+\frac{|\alpha|(1-\eta)}{|\alpha-1|}, 1+|\gamma|\}$. Further, we have

$$\|x'\|_\infty \leqslant \frac{1}{1-S}\|x''\|_1,$$

where $S = \min\{\frac{|1-\alpha|}{1-\eta}L, \frac{|1-\alpha|}{\alpha(1-\eta)}L, \frac{1}{|\gamma|}L\}$ if $S < 1$.

Case 3: $\alpha = 1$. Since $x(1) = x(\eta)$ there exists an $\omega \in (\eta, 1)$ with $x'(\omega) = 0$. It is then immediate that $\|x'\|_\infty \leqslant \|x''\|_1$. Also since $x(t) = x(0) + \int_0^t x'(s)\,\mathrm{d}s = \gamma x'(\zeta) + \int_0^t x'(s)\,\mathrm{d}s$, it is immediate that $\|x\|_\infty \leqslant (1 + |\gamma|)\|x'\|_\infty$.

This completes the proof of the lemma. □

THEOREM 3.29. *Let* $f : [0, 1] \times \mathbb{R}^2 \to \mathbb{R}$ *be a function satisfying Carathéodory's conditions. Assume that* (3.12) *holds. Also let* $\eta \in (0, 1)$ *be given and* $\alpha, \gamma \in \mathbb{R}$ *with* $1 + \gamma \neq \alpha(\gamma + \eta)$. *Moreover we assume that* $Q < 1$ *and* $S < 1$.

Then the BVP (3.38), (3.43) *has at least one solution in* $C^1[0, 1]$ *provided*

$$\begin{cases} \|p\|_1 + \|q\|_1 < 1, & \alpha \leqslant 0, \gamma = 0, \\ \|p\|_1 + \|q\|_1 < 1 - Q, & \alpha \leqslant 0, \gamma \neq 0, \\ L\|p\|_1 + \|q\|_1 < 1 - S, & \alpha > 0, \alpha \neq 1, \\ \big(1 + |\gamma|\big)\|p\|_1 + \|q\|_1 < 1, & \alpha = 1. \end{cases}$$

PROOF. Let X be the Banach space $C^1[0, 1]$ and Y denote the Banach space $L^1(0, 1)$ with their usual norms. We denote a linear mapping $L : D(L) \subset X \to Y$ by setting

$$D(L) = \{x \in W^{2,1}(0, 1)\colon\ x(0) = \gamma x'(\zeta),\ x(1) = \alpha x(\eta)\},$$

and for $x \in D(L)$,

$$Lx = x''.$$

We also define a nonlinear mapping $N : X \to Y$ by setting

$$(Nx)(t) = f\big(t, x(t), x'(t)\big), \quad t \in [0, 1].$$

We note that N is a bounded mapping from X into Y. Next, it is easy to see that the linear mapping $L : D(L) \subset X \to Y$, is one-to-one mapping. Next, the linear mapping $K : Y \to X$, defined for $y \in Y$ by

$$\begin{aligned}(Ky)(t) = {}& \int_0^t (t-s)y(s)\,\mathrm{d}s + \gamma \int_0^\zeta y(s)\,\mathrm{d}s \\ & + \frac{\gamma + t}{1 + \gamma - \alpha(\gamma + \eta)} \bigg[\alpha \int_0^\eta (\eta - s)y(s)\,\mathrm{d}s \\ & - \int_0^1 (1-s)y(s)\,\mathrm{d}s + \gamma(\alpha - 1)\int_0^\zeta y(s)\,\mathrm{d}s\bigg], \quad t \in [0, 1]\end{aligned}$$

is such that for $y \in Y$, $Ky \in D(L)$ and $LKy = y$; and for $u \in D(L)$, $KLu = u$. Furthermore, it follows easily using the Arzelá–Ascoli theorem that KN maps bounded subsets of X into a relatively compact subsets of X. Hence $KN : X \to X$ is a compact mapping.

We, next, note that $x \in C^1[0,1]$ is a solution of the BVP (3.38), (3.43) if and only if x is a solution to the operator equation

$$Lx = Nx + e.$$

Now, the operator equation $Lx = Nx + e$ is equivalent to the equation

$$x = KNx + Ke.$$

We apply the Leray–Schauder continuation theorem to obtain the existence of a solution for $x = KNx + Ke$ or equivalently to the BVP (3.38), (3.43).

To do this, it suffices to verify that the set of all possible solutions of the family of equations

$$x''(t) = \lambda f\bigl(t, x(t), x'(t)\bigr) + \lambda e(t), \quad t \in (0,1), \tag{3.47}$$

$$x(0) = \gamma x'(0), \qquad x(1) = \alpha x(\eta) \tag{3.48}$$

is, a priori, bounded in $C^1[0,1]$ by a constant independent of $\lambda \in [0,1]$.

(I) Assume that $\alpha \leqslant 0$, $\gamma = 0$. From Lemma 3.28 we have

$$\|x\|_\infty \leqslant \|x'\|_\infty \leqslant \|x''\|_1.$$

Let, now, $x(t)$ be a solution of (3.47)–(3.48) for some $\lambda \in [0,1]$, so that $x \in W^{2,1}(0,1)$ with $x(0) = \gamma x'(\zeta)$, $x(1) = \alpha x(\eta)$. We then get

$$\begin{aligned}\|x''\|_1 &= \lambda \bigl\| f\bigl(t, x(t), x'(t)\bigr) + e(t)\bigr\|_1 \\ &\leqslant \|p\|_1\|x\|_\infty + \|q\|_1\|x'\|_\infty + \|r\|_1 + \|e\|_1 \\ &\leqslant \bigl(\|p\|_1 + \|q\|_1\bigr)\|x''\|_1 + \|r\|_1 + \|e\|_1.\end{aligned}$$

It follows from our assumption that there is a constant c, independent of $\lambda \in [0,1]$, such that

$$\|x''\|_1 \leqslant c.$$

It is now immediate that the set of solutions of the family of equations (3.47)–(3.48) is, a priori, bounded in $C^1[0,1]$ by a constant independent of $\lambda \in [0,1]$.

(II) Assume that $\alpha \leqslant 0$, $\gamma \neq 0$. Then we have, by Lemma 3.28 that

$$\|x\|_\infty \leqslant \|x'\|_\infty, \qquad \|x'\|_\infty \leqslant \frac{1}{1-Q}\|x''\|_1.$$

We then get

$$\|x''\|_1 = \lambda \bigl\| f\bigl(t, x(t), x'(t)\bigr) + e(t)\bigr\|_1$$

$$\leqslant \|p\|_1\|x\|_\infty + \|q\|_1\|x'\|_\infty + \|r\|_1 + \|e\|_1$$
$$\leqslant \big[\|p\|_1 + \|q\|_1\big]\frac{1}{1-Q}\|x''\|_1 + \|r\|_1 + \|e\|_1.$$

We proceed as in case (I).

The process for the other cases is similar to the previous cases and we omit the details. This completes the proof of the theorem. □

We study now the multi-point BVP (3.38)–(3.39) using the a priori estimates that can be obtained for a four-point BVP (3.38), (3.43). This is because for every solution $x(t)$ of the BVP (3.38)–(3.39), there exist $\eta \in [\xi_1, \xi_{m-2}]$, $\zeta \in [\tau_1, \tau_{n-2}]$, depending on, $x(t)$, such that $x(t)$ is also a solution of the BVP (3.38), (3.43) with $\gamma = \sum_{i=1}^{m-2} c_i$ and $\alpha = \sum_{j=1}^{n-2} a_j$. The proof is quite similar to the proof of Theorem 3.29 and uses the a priori estimates obtained in the proof of Lemma 3.28 for the set of solutions of the family of equations (3.38), (3.43).

THEOREM 3.30. *Let* $f:[0,1]\times\mathbb{R}^2 \to \mathbb{R}$ *be a function satisfying Carathéodory's conditions. Assume that* (3.12) *holds. Let* $c_i, a_j \in \mathbb{R}$, *with all of the* c_i*'s* (*respectively,* a_j*'s*), *having the same sign,* $\xi_i, \tau_j \in (0,1)$, $i = 1,2,\dots,m-2$, $j = 1,2,\dots,n-2$, $0 < \xi_1 < \xi_2 < \cdots < \xi_{m-2} < 1$, $0 < \tau_1 < \tau_2 < \cdots < \tau_{n-2} < 1$ *be given. Suppose that*

$$1 + \left(\sum_{i=1}^{m-2} c_i\right)\left(1 - \sum_{j=1}^{n-2} a_j\right) - \sum_{j=1}^{n-2} a_j\tau_j \neq 0.$$

Let $\gamma = \sum_{i=1}^{m-2} c_i$ *and* $\alpha = \sum_{j=1}^{n-2} a_j$. *Moreover we assume that* $Q' < 1$, *and* $S' < 1$, *where* $M = \min\{\alpha, \frac{1}{\alpha}\} < 1$,

$$L' = \min\left\{\frac{1}{1-M}, 1 + \frac{1-\tau_1}{|1-\alpha|}, 1 + \frac{|\alpha|(1-\tau_1)}{|1-\alpha|}, 1 + |\gamma|\right\},$$
$$S' = \min\left\{\frac{|1-\alpha|}{1-\tau_{n-2}}L, \frac{|1-\alpha|}{\alpha(1-\tau_{n-2})}L, \frac{1}{|\gamma|}L\right\},$$
$$Q' = \min\left\{\frac{1-\alpha}{1-\tau_{n-2}}, \frac{1-\alpha}{|\alpha|(1-\tau_{n-2})}, \frac{1}{|\gamma|}\right\}.$$

Then the BVP (3.38)–(3.39) *has at least one solution in* $C^1[0,1]$ *provided*

$$\begin{cases} \|p\|_1 + \|q\|_1 < 1, & \alpha \leqslant 0, \gamma = 0, \\ \|p\|_1 + \|q\|_1 < 1 - Q', & \alpha \leqslant 0, \gamma \neq 0, \\ L'\|p\|_1 + \|q\|_1 < 1 - S', & \alpha > 0, \alpha \neq 1, \\ \big(1 + |\gamma|\big)\|p\|_1 + \|q\|_1 < 1, & \alpha = 1. \end{cases}$$

PROOF. Let X be the Banach space $C^1[0,1]$ and Y denote the Banach space $L^1(0,1)$ with their usual norms. We denote a linear mapping $L: D(L) \subset X \to Y$ by setting

$$D(L) = \left\{ x \in W^{2,1}(0,1)\colon\ x(0) = \sum_{i=1}^{m-2} c_i x'(\xi_i),\ x(1) = \sum_{j=1}^{n-2} a_j x(\tau_j) \right\},$$

and for $x \in D(L)$,

$$Lx = x''.$$

We also define a nonlinear mapping $N: X \to Y$ by setting

$$(Nx)(t) = f\bigl(t, x(t), x'(t)\bigr), \quad t \in [0,1].$$

We note that N, is a bounded mapping from X into Y. Next, it is easy to see that the linear mapping $L: D(L) \subset X \to Y$, is one-to-one mapping. Next, the linear mapping $K: Y \to X$, defined for $y \in Y$ by

$$(Ky)(t) = \int_0^t (t-s)y(s)\,\mathrm{d}s + ct + k, \quad t \in [0,1],$$

where c and k are given by

$$\begin{aligned}
&\left[1 + \left(\sum_{i=1}^{m-2} c_i\right)\left(1 - \sum_{j=1}^{n-2} a_j\right) - \sum_{j=1}^{n-2} a_j \tau_j\right] c \\
&\quad = \left(\sum_{j=1}^{n-2} a_j - 1\right)\left(\sum_{i=1}^{m-2} c_i \int_0^{\xi_i} y(s)\,\mathrm{d}s\right) \\
&\qquad + \sum_{j=1}^{n-2} a_j \int_0^{\tau_j} (\tau_j - s)y(s)\,\mathrm{d}s - \int_0^1 (1-s)y(s)\,\mathrm{d}s
\end{aligned}$$

and

$$\begin{aligned}
&\left[1 + \left(\sum_{i=1}^{m-2} c_i\right)\left(1 - \sum_{j=1}^{n-2} a_j\right) - \sum_{j=1}^{n-2} a_j \tau_j\right] k = \sum_{i=1}^{m-2} c_i \sum_{j=1}^{n-2} a_j \int_0^{\tau_j} (\tau_j - s)y(s)\,\mathrm{d}s \\
&\qquad - \sum_{i=1}^{m-2} c_i \int_0^1 (1-s)y(s)\,\mathrm{d}s + \left(1 - \sum_{j=1}^{n-2} a_j \tau_j\right) \sum_{i=1}^{m-2} c_i \int_0^{\xi_i} y(s)\,\mathrm{d}s,
\end{aligned}$$

is such that for $y \in Y$, $Ky \in D(L)$and $LKy = y$; and for $u \in D(L)$, $KLu = u$. Furthermore, it follows easily using the Arzelá–Ascoli theorem that KN maps bounded subsets of X into a relatively compact subset of X. Hence $KN: X \to X$ is a compact mapping.

We, next, note that $x \in C^1[0,1]$ is a solution of the BVP (3.38)–(3.39) if and only if x is a solution to the operator equation

$$Lx = Nx + e.$$

Now, the operator equation $Lx = Nx + e$ is equivalent to the equation

$$x = KNx + Ke.$$

We apply the Leray–Schauder continuation theorem to obtain the existence of a solution for $x = KNx + Ke$ or equivalently to the BVP (3.38)–(3.39).

To do this, it suffices to verify that the set of all possible solutions of the family of equations

$$x''(t) = \lambda f\big(t, x(t), x'(t)\big) + \lambda e(t), \quad t \in (0,1), \tag{3.49}$$

$$x(0) = \sum_{i=1}^{m-2} c_i x'(\xi_i), \qquad x(1) = \sum_{j=1}^{n-2} a_j x(\tau_j) \tag{3.50}$$

is, a priori, bounded in $C^1[0,1]$ by a constant independent of $\lambda \in [0,1]$.

Let, now, $x(t)$ be a solution of (3.49)–(3.50) for some $\lambda \in [0,1]$, so that $x \in W^{2,1}(0,1)$ with $x(0) = \sum_{i=1}^{m-2} c_i x'(\xi_i)$, $x(1) = \sum_{j=1}^{n-2} a_j x(\tau_j)$. Accordingly, there exist $\zeta \in [\xi_1, \xi_{m-2}]$ and $\eta \in [\tau_1, \tau_{n-2}]$ depending on $x(t)$, such that $x(t)$ is a solution of the four point BVP

$$x''(t) = \lambda f\big(t, x(t), x'(t)\big) + \lambda e(t), \quad t \in (0,1),$$

$$x(0) = \gamma x'(\zeta), \qquad x(1) = \alpha x(\eta).$$

It then follows, as in the proof of Theorem 3.30 that there is a constant c, independent of $\lambda \in [0,1]$, and $\eta \in [\xi_1, \xi_{m-2}]$, $\zeta \in [\tau_1, \tau_{n-2}]$ such that

$$\|x\|_\infty \leqslant c_1 \|x'\|_\infty \leqslant c_2 \|x''\|_1 \leqslant c,$$

where c_1, c_2 are constants independent of λ, η, ζ. Thus the set of solutions of the family of equations is, a priori, bounded in $C^1[0,1]$ by a constant, independent of $\lambda \in [0,1]$. This completes the proof of the theorem. □

Theorems 3.29 and 3.30 are taken from [35]. Similar results for the BVP (3.38), (3.40) are proved in [35] and for the BVPs (3.38), (3.41) and (3.38), (3.42) in [36].

3.8. *The general case*

Let $f : [0,1] \times \mathbb{R}^2 \to \mathbb{R}$ be either a continuous or a Carathéodory's function and $e(t) \in L^1[0,1]$. Let ξ_i, η_j, c_i, a_j, $i = 1, 2, \ldots, m-2$, $j = 1, 2, \ldots, n-2$, $0 < \xi_1 < \xi_2 < \cdots <$

$\xi_{m-2} < 1$, $0 < \eta_1 < \eta_2 < \cdots < \eta_{n-2} < 1$ be given. Consider the following second-order ordinary differential equation:

$$x''(t) = f\bigl(t, x(t), x'(t)\bigr) + e(t), \quad t \in (0,1), \tag{3.51}$$

subject to one of the following boundary value conditions:

$$x(0) = \sum_{i=1}^{m-2} c_i x(\xi_i), \qquad x(1) = \sum_{j=1}^{n-2} a_j x(\eta_j), \tag{3.52}$$

$$x(0) = \sum_{i=1}^{m-2} c_i x(\xi_i), \qquad x'(1) = \sum_{j=1}^{n-2} a_j x(\eta_j), \tag{3.53}$$

$$x'(0) = \sum_{i=1}^{m-2} c_i x(\xi_i), \qquad x(1) = \sum_{j=1}^{n-2} a_j x(\eta_j), \tag{3.54}$$

$$x(0) = \sum_{i=1}^{m-2} c_i x'(\xi_i), \qquad x(1) = \sum_{j=1}^{n-2} a_j x'(\eta_j), \tag{3.55}$$

$$x(0) = \sum_{i=1}^{m-2} c_i x'(\xi_i), \qquad x'(1) = \sum_{j=1}^{n-2} a_j x(\eta_j), \tag{3.56}$$

$$x(0) = \sum_{i=1}^{m-2} c_i x(\xi_i), \qquad x'(1) = \sum_{j=1}^{n-2} a_j x'(\eta_j), \tag{3.57}$$

$$x(0) = \sum_{i=1}^{m-2} c_i x'(\xi_i), \qquad x'(1) = \sum_{j=1}^{n-2} a_j x'(\eta_j). \tag{3.58}$$

When all the c_i's have the same sign and also all the a_j's have the same sign, it is known that existence of a solution for (3.51) with boundary conditions (3.52)–(3.58) can be obtained via existence subject to the respective four-point boundary conditions

$$x(0) = \gamma x(\xi), \qquad x(1) = \alpha x(\eta), \tag{3.59}$$

$$x(0) = \gamma x(\xi), \qquad x'(1) = \alpha x(\eta), \tag{3.60}$$

$$x'(0) = \gamma x'(\xi), \qquad x(1) = \alpha x(\eta), \tag{3.61}$$

$$x'(0) = \gamma x'(\xi), \qquad x'(1) = \alpha x'(\eta), \tag{3.62}$$

$$x(0) = \gamma x'(\xi), \qquad x(1) = \alpha x(\eta), \tag{3.63}$$

$$x(0) = \gamma x'(\xi), \qquad x'(1) = \alpha x'(\eta), \tag{3.64}$$

$$x(0) = \gamma x(\xi), \qquad x'(1) = \alpha x'(\eta), \tag{3.65}$$

where $\xi \in [\xi_1, \xi_{m-2}]$, $\eta \in [\eta_1, \eta_{n-2}]$, $\gamma = \sum_{i=1}^{m-2} c_i$, $\alpha = \sum_{j=1}^{n-2} a_j$.

When all the c_i's have the same sign and also all the a_j's have no same sign, the existence of a solution for (3.51) with boundary value conditions (3.52)–(3.58) can be obtained via existence subject to the following boundary conditions

$$x(0) = \gamma x(\xi), \qquad x(1) = \sum_{j=1}^{n-2} a_j x(\eta_j), \tag{3.66}$$

$$x(0) = \gamma x(\xi), \qquad x'(1) = \sum_{j=1}^{n-2} a_j x'(\eta_j), \tag{3.67}$$

$$x'(0) = \gamma x(\xi), \qquad x(1) = \sum_{j=1}^{n-2} a_j x(\eta_j), \tag{3.68}$$

$$x'(0) = \gamma x'(\xi), \qquad x'(1) = \sum_{j=1}^{n-2} a_j x'(\eta_j), \tag{3.69}$$

$$x(0) = \gamma x'(\xi), \qquad x(1) = \sum_{j=1}^{n-2} a_j x(\eta_j), \tag{3.70}$$

$$x(0) = \gamma x'(\xi), \qquad x'(1) = \sum_{j=1}^{n-2} a_j x'(\eta_j), \tag{3.71}$$

$$x(0) = \gamma x(\xi), \qquad x'(1) = \sum_{j=1}^{n-2} a_j x'(\eta_j), \tag{3.72}$$

where $\xi \in [\xi_1, \xi_{m-2}]$, $\gamma = \sum_{i=1}^{m-2} c_i$.

When all the c_i's do not have the same sign and also all the a_j's have the same sign, the existence of a solution for (3.51) with boundary value conditions (3.52)–(3.58) can be obtained via existence subject to the following boundary conditions

$$x(0) = \sum_{i=1}^{m-2} c_i x(\xi_i), \qquad x(1) = \alpha x(\eta), \tag{3.73}$$

$$x(0) = \sum_{i=1}^{m-2} c_i x(\xi_i), \qquad x'(1) = \alpha x'(\eta), \tag{3.74}$$

$$x'(0) = \sum_{i=1}^{m-2} c_i x'(\xi_i), \qquad x(1) = \alpha x(\eta), \tag{3.75}$$

$$x'(0)=\sum_{i=1}^{m-2}c_i x'(\xi_i),\qquad x'(1)=\alpha x'(\eta), \tag{3.76}$$

$$x(0)=\sum_{i=1}^{m-2}c_i x'(\xi_i),\qquad x(1)=\alpha x(\eta), \tag{3.77}$$

$$x(0)=\sum_{i=1}^{m-2}c_i x'(\xi_i),\qquad x'(1)=\alpha x'(\eta), \tag{3.78}$$

$$x(0)=\sum_{i=1}^{m-2}c_i x(\xi_i),\qquad x'(1)=\alpha x'(\eta), \tag{3.79}$$

where $\eta \in [\eta_1, \eta_{n-2}], \alpha = \sum_{j=1}^{n-2} a_j$.

For certain boundary condition case such that the linear operator $Lx = x''$, defined in a suitable Banach space, is invertible, is the so-called nonresonance case. Otherwise, the so-called resonance case.

Existence results were given for the BVPs:

- (3.51)–(3.52) in [29] for the nonresonance case and in [59] for resonance case,
- (3.51), (3.54) and (3.51), (3.55) in [59] for resonance case,
- (3.51), (3.57) in [29] for nonresonance case,
- (3.51), (3.58) in [28] for nonresonance case,
- (3.51), (3.59), (3.51), (3.61), (3.51), (3.62) and (3.51), (3.65) in [61] for resonance case,
- (3.51), (3.66), (3.51), (3.67), (3.51), (3.68) and (3.51), (3.69) in [60] for resonance case,
- (3.51), (3.73), (3.51), (3.74), (3.51), (3.75) and (3.51), (3.76) in [62] for resonance case.

For the BVP (3.38), (3.52) we report an existence result for the nonresonance case from [29].

THEOREM 3.31. *Let* $f : [0,1] \times \mathbb{R}^2 \to \mathbb{R}$ *be a function satisfying Carathéodory's conditions. Assume that* (3.12) *holds. Let* $c_i, a_j \in \mathbb{R}$, *with all of the* c_i*'s* (*respectively,* a_j*'s*), *not having the same sign,* $\xi_i, \eta_j \in (0,1)$, $i = 1,2,\ldots,m-2$, $j = 1,2,\ldots,n-2$, $0 < \xi_1 < \xi_2 < \cdots < \xi_{m-2} < 1$, $0 < \eta_1 < \eta_2 < \cdots < \eta_{n-2} < 1$ *be given. Suppose that*

$$\left(\sum_{i=1}^{m-2} c_i\xi_i\right)\left(1-\sum_{j=1}^{n-2}a_j\right) \neq \left(1-\sum_{j=1}^{n-2}c_i\right)\left(\sum_{j=1}^{n-2}a_j\eta_j - 1\right).$$

Then the BVP (3.51)–(3.52) *has at least one solution in* $C^1[0,1]$ *provided*

$$Q\big(M\|p\|_1 + \|q\|_1\big) < 1,$$

where

$$M=\min\left\{\frac{1}{\left|\sum_{i=1}^{m-2}c_i\right|}\left(\sum_{i=1}^{m-2}|c_i|\lambda_i+\frac{\sum_{i=1}^{m-2}|c_i\xi_i|}{\left|1-\sum_{i=1}^{m-2}c_i\right|}\right),\right.$$
$$\frac{1}{\left|\sum_{j=1}^{n-2}a_j\right|}\left(\sum_{j=1}^{n-2}|a_i|\mu_j+\frac{\sum_{j=1}^{n-2}|c_j(1-\eta_j)|}{\left|1-\sum_{j=1}^{n-2}a_j\right|}\right),$$
$$\left.1+\frac{\sum_{i=1}^{m-2}|c_i\xi_i|}{\left|1-\sum_{i=1}^{m-2}c_i\right|},1+\frac{\sum_{j=1}^{n-2}|c_j(1-\eta_j)|}{\left|1-\sum_{j=1}^{n-2}a_j\right|}\right\},$$

$\lambda_i=\max\{\xi_i,1-\xi_i\}$, $i=1,\dots,m-2$, $\mu_j=\max\{\eta_j,1-\eta_j\}$, $j=1,\dots,n-2$ *and*

$$Q=\min\left\{\frac{\sum_{i=1}^{m-2}|c_i\xi_i|}{\left|\sum_{i=1}^{m-2}c_i\xi_i\right|-M\left|1-\sum_{i=1}^{m-2}c_i\right|},\right.$$
$$\left.\frac{\sum_{j=1}^{n-2}|a_j(1-\eta_j)|}{\left|\sum_{i=j}^{n-2}a_j(1-\eta_j)\right|-M\left|\sum_{j=1}^{n-2}a_j-1\right|}\right\}.$$

For resonance case Liu in [59] gave existence results for the BVP (3.51)–(3.52) in the following cases:

(1) $\sum_{i=1}^{m-2}c_i\xi_i=0$, $\gamma=1$, $\alpha=1$, $\sum_{i=1}^{m-2}c_i\xi_i^2\neq 0$, $\sum_{j=1}^{n-2}a_j\eta_j^2\neq 1$.

(2) $\sum_{i=1}^{m-2}c_i\xi_i\neq 0$, $\gamma=1$, $\alpha=1$, $\sum_{i=1}^{n-2}a_j\eta_j=1$, $\sum_{j=1}^{n-2}a_j\eta_j^2\neq 1$.

(3) $\sum_{i=1}^{m-2}c_i\xi_i=0$, $\gamma\neq 1$, $\alpha=1$, $\sum_{i=1}^{n-2}a_j\eta_j=1$, $\sum_{j=1}^{n-2}a_j\eta_j^2\neq 1$.

(4) $\sum_{i=1}^{m-2}c_i\xi_i=0$, $\gamma=1$, $\alpha\neq 1$, $\sum_{i=1}^{n-2}a_j\eta_j=1$, $\sum_{i=1}^{m-2}c_i\xi_i^2\neq 0$.

We give an existence result at resonance, for the BVP (3.51)–(3.52) in the case (1), i.e. when

$$\sum_{i=1}^{m-2}c_i\xi_i=0,\qquad \gamma=1,\qquad \alpha=1,\qquad \sum_{i=1}^{m-2}c_i\xi_i^2\neq 0,\qquad \sum_{j=1}^{n-2}a_j\eta_j^2\neq 1.$$

THEOREM 3.32. *Let* $f:[0,1]\times\mathbb{R}^2\to\mathbb{R}$ *be a continuous function. Assume that either there exists* $m_1\in\{1,2,\dots,m-3\}$ *such that* $c_i<0$ $(1\leqslant i\leqslant m_1)$, $c_i>0$ $(m_1+1\leqslant i\leqslant m-2)$, *or there exists* $n_1\in\{1,2,\dots,n-3\}$ *such that* $a_j>0$ $(1\leqslant j\leqslant n_1)$, $a_j<0$ $(n_1+1\leqslant j\leqslant n-2)$, *furthermore*

(H1) *There exist functions* a,b,c,r *in* $L^1[0,1]$, *and constant* $\theta\in[0,1)$ *such that for all* $(x,y)\in\mathbb{R}^2$, $t\in[0,1]$ *either*

$$\left|f(t,x,y)\right|\leqslant a(t)|x|+b(t)|y|+c(t)|y|^\theta+r(t)$$

or else

$$\left|f(t,x,y)\right|\leqslant a(t)|x|+b(t)|y|+c(t)|x|^\theta+r(t).$$

(H2) *There exists constant* $M > 0$ *such that, for* $x \in \operatorname{dom}(L)$, *if* $|x(t)| > M$ *for all* $t \in [0, 1]$, *then*

$$\sum_{i=1}^{m-2} c_i \int_0^{\xi_i} \int_0^s \left[f\big(\tau, x(\tau), x'(\tau)\big) + e(\tau) \right] \mathrm{d}\tau \, \mathrm{d}s \neq 0.$$

(H3) *There exists constant* $M^* > 0$ *such that for any* $d \in \mathbb{R}$, *if* $|d| > M^*$, *then either*

$$d \sum_{i=1}^{m-2} c_i \int_0^{\xi_i} \int_0^s \left[f(\tau, d, 0) + e(\tau) \right] \mathrm{d}\tau \, \mathrm{d}s < 0$$

or else

$$d \sum_{i=1}^{m-2} c_i \int_0^{\xi_i} \int_0^s \left[f(\tau, d, 0) + e(\tau) \right] \mathrm{d}\tau \, \mathrm{d}s > 0.$$

Then, for every $e \in L^1[0, 1]$, *the BVP* (3.51)–(3.52) *in the case* (1), *i.e. when* $\sum_{i=1}^{m-2} c_i \xi_i = 0$, $\gamma = 1$, $\alpha = 1$, $\sum_{i=1}^{m-2} c_i \xi_i^2 \neq 0$, $\sum_{j=1}^{n-2} a_j \eta_j^2 \neq 1$, *has at least one solution in* $C^1[0, 1]$ *provided*

$$\|a\|_1 + \|b\|_1 < \frac{1}{\Delta_1 + 1}, \quad \textit{where } \Delta_1 = a + \frac{\sum_{i=j}^{n-2} |a_j|(1 - \eta_j)}{\left|1 - \sum_{j=1}^{n-2} a_j \eta_j\right|}.$$

3.9. *Positive solutions of some nonlocal boundary value problems*

There is much attention focused on question of positive solutions of BVPs for ordinary differential equations. Much of interest is due to the applicability of certain Krasnosel'skii fixed point theorems or the Leggett–Williams multiple fixed point theorem, or a synthesis of both to obtain positive solutions or multiple positive solutions which lie in a cone. Here we present some of the results on positive solutions of some nonlocal BVPs.

Consider the differential equation

$$x'' + a(t) f(x) = 0, \quad t \in (0, 1) \tag{3.80}$$

with the boundary conditions

$$x(0) = 0, \qquad \alpha x(\eta) = x(1), \tag{3.81}$$

where $0 < \eta < 1$. Our purpose here is to give some existence results for positive solutions to (3.80)–(3.81), assuming that $\alpha\eta < 1$ and f is either superlinear or sublinear.

Set

$$f_0 = \lim_{x\to 0+} \frac{f(x)}{x}, \qquad f_\infty = \lim_{x\to\infty} \frac{f(x)}{x}.$$

Then $f_0 = 0$ and $f_\infty = \infty$ correspond to the superlinear case, and $f_0 = \infty$ and $f_\infty = 0$ correspond to the sublinear case. By the *positive solution* of the BVP (3.80)–(3.81) we understand a function $x(t)$ which is positive on $0 < t < 1$ and satisfies the differential equation (3.80) and the boundary conditions (3.81).

The key tool in our approach is the following Krasnosel'skii's fixed point theorem in a cone [54] (see also [21]).

THEOREM 3.33. *Let E be a Banach space, and let $K \subset E$ be a cone. Assume Ω_1, Ω_2 are open bounded subsets of E with $0 \in \Omega_1$, $\overline{\Omega}_1 \subset \Omega_2$, and let*

$$A : K \cap \left(\overline{\Omega}_2 \setminus \Omega_1\right) \longrightarrow K$$

be a completely continuous operator such that

(i) $\|Au\| \leqslant \|u\|$, $u \in K \cap \partial\Omega_1$, *and* $\|Au\| \geqslant \|u\|$, $u \in K \cap \partial\Omega_2$; *or*

(ii) $\|Au\| \geqslant \|u\|$, $u \in K \cap \partial\Omega_1$, *and* $\|Au\| \leqslant \|u\|$, $u \in K \cap \partial\Omega_2$.

Then A has a fixed point in $K \cap (\overline{\Omega}_2 \setminus \Omega_1)$.

We give first some preliminary lemmas.

LEMMA 3.34. *Let $\alpha\eta \neq 1$ then for $y \in C[0,1]$, the problem*

$$x''(t) + y(t) = 0, \quad t \in (0,1), \tag{3.82}$$

$$x(0) = 0, \qquad \alpha x(\eta) = x(1) \tag{3.83}$$

has a unique solution

$$x(t) = -\int_0^t (t-s)y(s)\,\mathrm{d}s - \frac{\alpha t}{1-\alpha\eta}\int_0^\eta (\eta - s)y(s)\,\mathrm{d}s + \frac{t}{1-\alpha\eta}\int_0^1 (1-s)y(s)\,\mathrm{d}s.$$

LEMMA 3.35. *Let $0 < \alpha < \frac{1}{\eta}$. If $y \in C[0,1]$ and $y \geqslant 0$, for $t \in (0,1)$ then the unique solution x of the problem* (3.82)–(3.83) *satisfies $x(t) \geqslant 0$, $t \in [0,1]$.*

PROOF. From the fact that $x''(t) = -y(t) \leqslant 0$, we know that the graph of $x(t)$ is concave down on $(0,1)$. So, if $x(1) \geqslant 0$, then the concavity of x and the boundary condition $x(0) = 0$ imply that $x \geqslant 0$ for $t \in [0,1]$. If $x(1) < 0$, then we have that $x(\eta) < 0$ and $x(1) = \alpha x(\eta) > \frac{1}{\eta}x(\eta)$ which contradicts to the concavity of x. □

LEMMA 3.36. *Let* $\alpha\eta > 1$. *If* $y \in C[0,1]$ *and* $y \geqslant 0$, *for* $t \in (0,1)$ *then* (3.82)–(3.83) *has no positive solution.*

PROOF. Assume that (3.82)–(3.83) has a positive solution x. If $x(1) > 0$, then $x(\eta) > 0$ and $\frac{x(1)}{1} = \frac{\alpha x(\eta)}{1} > \frac{x(\eta)}{\eta}$ which contradicts to the concavity of x. If $x(1) = 0$ and $x(\tau) > 0$ for some $\tau \in (0,1)$, then $x(\eta) - x(1) = 0$, $\tau = \eta$. If $\tau \in (0,\eta)$, then $x(\tau) > x(\eta) = x(1)$, which contradicts to the concavity of x again. □

LEMMA 3.37. *Let* $0 < \alpha < \frac{1}{\eta}$. *If* $y \in C[0,1]$ *and* $y \geqslant 0$, *for* $t \in (0,1)$ *then the unique solution* x *of the problem* (3.82)–(3.83) *satisfies*

$$\inf_{t\in[\eta,1]} x(t) \geqslant \gamma \|x\|,$$

where $\gamma = \min\{\alpha\eta, \frac{\alpha(1-\eta)}{1-\alpha\eta}, \eta\}$.

PROOF. We divide the proof into two steps.

Step 1. We deal with the case $0 < \alpha < 1$. In this case, by Lemma 3.35, we know that $x(\eta) \geqslant x(1)$. Set

$$x(\bar{t}) = \|x\|.$$

If $\bar{t} \leqslant \eta < 1$, then $\min_{t\in[\eta,1]} x(t) = x(1)$ and

$$x(\bar{t}) \leqslant x(1) + \frac{x(1) - x(\eta)}{1-\eta}(0-1) = x(1)\frac{1-\alpha\eta}{\alpha(1-\eta)}.$$

Then

$$\min_{t\in[\eta,1]} x(t) \geqslant \frac{\alpha(1-\eta)}{1-\alpha\eta}.$$

If $\eta < \bar{t} < 1$, then $\min_{t\in[\eta,1]} x(t) = x(1)$. From the concavity of x, we know that $\frac{x(\eta)}{\eta} \geqslant \frac{x(\bar{t})}{\bar{t}}$ which combined with boundary condition $\alpha x(\eta) = x(1)$, gives $\frac{x(1)}{\alpha\eta} \geqslant \frac{x(\bar{t})}{\bar{t}} \geqslant x(\bar{t}) = \|x\|$. Therefore

$$\min_{t\in[\eta,1]} x(t) \geqslant \alpha\eta\|x\|.$$

Step 2. We deal with the case $1 < \alpha < \frac{1}{\eta}$. In this case, we have $x(\eta) \leqslant x(1)$. Set

$$x(\bar{t}) = \|x\|.$$

Then we can choose $\bar{t}$ such that $\eta \leqslant \bar{t} \leqslant 1$. This contradicts to the concavity of x. From $x(\eta) \leqslant x(1)$ and the concavity of x, we know that $\min_{t\in[\eta,1]} x(t) = x(\eta)$. Using the concavity of x and Lemma 3.35, we have $\frac{x(\eta)}{\eta} \geqslant \frac{x(\bar{t})}{\bar{t}}$ which implies that

$$\min_{t\in[\eta,1]} x(t) \geqslant \eta\|x\|.$$

This completes the proof. □

The main result here is the following:

THEOREM 3.38. *Assume that*

(A1) $f \in C([0,\infty),[0,\infty))$;

(A2) $a \in C([0,1],[0,\infty))$ *and there exists* $x_0 \in [\eta,1]$ *such that* $a(x_0) > 0$.

Then the BVP (3.80)–(3.81) *has at least one positive solution in the case*

(i) $f_0 = 0$ *and* $f_\infty = \infty$ (*superlinear*) *or*

(ii) $f_0 = \infty$ *and* $f_\infty = 0$ (*sublinear*).

PROOF. (i) Suppose that $f_0 = 0$ and $f_\infty = \infty$. We wish to show the existence of a positive solution of (3.80)–(3.81). Now (3.80)–(3.81) has a solution $x = x(t)$ if and only if x solves the operator equation

$$\begin{aligned} x(t) &= -\int_0^t (t-s)a(s)f\bigl(x(s)\bigr)\,\mathrm{d}s - \frac{\alpha t}{1-\alpha\eta}\int_0^\eta (\eta-s)a(s)f\bigl(x(s)\bigr)\,\mathrm{d}s \\ &\quad + \frac{t}{1-\alpha\eta}\int_0^1 (1-s)a(s)f\bigl(x(s)\bigr)\,\mathrm{d}s \\ &:= Ax(t). \end{aligned}$$

Denote

$$K = \Bigl\{x\colon\ x \in C[0,1], x \geqslant 0, \min_{\eta\leqslant t\leqslant 1} x(t) \geqslant \gamma\|x\|\Bigr\}.$$

It is obvious that K is a cone in $C[0,1]$. Moreover, by Lemma 3.37, $AK \subset K$. It is also easy to check that $A : K \to K$ is completely continuous.

Now $f_0 = 0$, we may choose $H_1 > 0$ so that $f(x) \leqslant \epsilon x$, for $0 < x < H_1$, where $\epsilon > 0$ satisfies

$$\frac{\epsilon}{1-\alpha\eta}\int_0^1 (1-s)a(s)\,\mathrm{d}s \leqslant 1.$$

Thus, if $x \in K$ and $\|x\| = H_1$ we get

$$Ax(t) \leqslant \frac{t}{1-\alpha\eta}\int_0^1 (1-s)a(s)f\bigl(x(s)\bigr)\,\mathrm{d}s$$

$$\begin{aligned}
&\leqslant \frac{t}{1-\alpha\eta}\int_0^1 (1-s)a(s)\epsilon x(s)\,\mathrm{d}s\\
&\leqslant \frac{\epsilon}{1-\alpha\eta}\int_0^1 (1-s)a(s)\,\mathrm{d}s\|x\|\\
&\leqslant \frac{\epsilon}{1-\alpha\eta}\int_0^1 (1-s)a(s)\,\mathrm{d}sH_1.
\end{aligned}$$

Now if we let

$$\Omega_1 = \bigl\{x \in C[0,1]:\ \|x\| < H_1\bigr\},$$

then $\|Ax\| \leqslant \|x\|$, for $x \in K \cap \partial\Omega_1$.

Further since $f_\infty = \infty$, there exists $\widehat{H}_2 > 0$ such that $f(x) \geqslant \rho x$, for $x \geqslant \widehat{H}_2$, where ρ is chosen so that

$$\rho\frac{\eta\gamma}{1-\alpha\eta}\int_\eta^1 (1-s)a(s)\,\mathrm{d}s > 1.$$

Let $H_2 = \max\{2H_1, \frac{\widehat{H}_2}{\gamma}\}$ and $\Omega_2 = \{x \in C[0,1]:\ \|x\| < H_2\}$, then $x \in K$ and $\|x\| = H_2$ implies

$$\min_{\eta\leqslant t\leqslant 1} x(t) \geqslant \gamma\|x\| \geqslant \widehat{H}_2,$$

and so

$$\begin{aligned}
Ax(\eta) &= -\int_0^\eta (\eta-s)a(s)f\bigl(x(s)\bigr)\,\mathrm{d}s - \frac{\alpha\eta}{1-\alpha\eta}\int_0^\eta (\eta-s)a(s)f\bigl(x(s)\bigr)\,\mathrm{d}s\\
&\quad + \frac{\eta}{1-\alpha\eta}\int_0^1 (1-s)a(s)f\bigl(x(s)\bigr)\,\mathrm{d}s\\
&= -\frac{1}{1-\alpha\eta}\int_0^\eta (\eta-s)a(s)f\bigl(x(s)\bigr)\,\mathrm{d}s\\
&\quad + \frac{\eta}{1-\alpha\eta}\int_0^1 (1-s)a(s)f\bigl(x(s)\bigr)\,\mathrm{d}s\\
&= \frac{\eta}{1-\alpha\eta}\int_\eta^1 a(s)f\bigl(x(s)\bigr)\,\mathrm{d}s + \frac{1}{1-\alpha\eta}\int_0^\eta sa(s)f\bigl(x(s)\bigr)\,\mathrm{d}s\\
&\quad - \frac{\eta}{1-\alpha\eta}\int_0^1 sa(s)f\bigl(x(s)\bigr)\,\mathrm{d}s\\
&\geqslant \frac{\eta}{1-\alpha\eta}\int_\eta^1 a(s)f\bigl(x(s)\bigr)\,\mathrm{d}s
\end{aligned}$$

$$- \frac{\eta}{1-\alpha\eta}\int_{\eta}^{1} sa(s)f\bigl(x(s)\bigr)\,\mathrm{d}s \quad (\text{by } \eta < 1)$$

$$= \frac{\eta}{1-\alpha\eta}\int_{\eta}^{1} (1-s)a(s)f\bigl(x(s)\bigr)\,\mathrm{d}s.$$

Hence, for $x \in K \cap \partial\Omega_2$,

$$\|Ax\| \geqslant \rho\frac{\eta\gamma}{1-\alpha\eta}\int_{\eta}^{1}(1-s)a(s)\,\mathrm{d}s\,\|x\| \geqslant \|x\|.$$

Therefore, by the first part of Theorem 3.33, it follows that A has a fixed point in $K \cap (\overline{\Omega_2} \setminus \Omega_1)$, such that $H_1 \leqslant \|x\| \leqslant H_2$. This completes the superlinear part of the theorem.

(ii) Suppose next that $f_0 = \infty$ and $f_\infty = 0$. We first choose $H_3 > 0$ such that $f(x) \geqslant Mx$ for $0 < x < H_3$, where

$$M\gamma\left(\frac{\eta}{1-\alpha\eta}\right)\int_{\eta}^{1}(1-s)a(s)\,\mathrm{d}s \geqslant 1.$$

Then

$$\begin{aligned}
Ax(\eta) &= -\int_0^{\eta}(\eta-s)a(s)f\bigl(x(s)\bigr)\,\mathrm{d}s - \frac{\alpha\eta}{1-\alpha\eta}\int_0^{\eta}(\eta-s)a(s)f\bigl(x(s)\bigr)\,\mathrm{d}s \\
&\quad + \frac{\eta}{1-\alpha\eta}\int_0^{1}(1-s)a(s)f\bigl(x(s)\bigr)\,\mathrm{d}s \\
&\geqslant \frac{\eta}{1-\alpha\eta}\int_{\eta}^{1}(1-s)a(s)f\bigl(x(s)\bigr)\,\mathrm{d}s \\
&\geqslant \frac{\eta}{1-\alpha\eta}\int_{\eta}^{1}(1-s)a(s)Mx(s)\,\mathrm{d}s \\
&\geqslant \frac{\eta}{1-\alpha\eta}\int_{\eta}^{1}(1-s)a(s)M\gamma\,\mathrm{d}s\,\|x\| \\
&\geqslant H_3.
\end{aligned}$$

Thus, we may let $\Omega_3 = \{x \in C[0,1]\colon\ \|x\| < H_3\}$ so that

$$\|Ax\| \geqslant \|x\|, \quad x \in K \cap \partial\Omega_3.$$

Now, since $f_\infty = 0$, there exist $\widehat{H}_4 > 0$ so that $f(x) \leqslant \lambda x$ for $x \geqslant \widehat{H}_4$, where $\lambda > 0$ satisfies

$$\frac{\lambda}{1-\alpha\eta}\int_0^{1}(1-s)a(s)\,\mathrm{d}s \leqslant 1.$$

We consider two cases:

Case 1. Suppose f is bounded, say $f(x) \leqslant N$ for all $x \in [0, \infty)$. In this case choose

$$H_4 = \max\left\{2H_3, \frac{N}{1-\alpha\eta}\int_0^1 (1-s)a(s)\,\mathrm{d}s\right\}$$

so that for $x \in K$ with $\|x\| = H_4$ we have

$$\begin{aligned}
Ax(t) &= -\int_0^t (t-s)a(s)f\big(x(s)\big)\,\mathrm{d}s - \frac{\alpha t}{1-\alpha\eta}\int_0^\eta (\eta-s)a(s)f\big(x(s)\big)\,\mathrm{d}s \\
&\quad + \frac{t}{1-\alpha\eta}\int_0^1 (1-s)a(s)f\big(x(s)\big)\,\mathrm{d}s \\
&\leqslant \frac{t}{1-\alpha\eta}\int_0^1 (1-s)a(s)f\big(x(s)\big)\,\mathrm{d}s \\
&\leqslant \frac{1}{1-\alpha\eta}\int_0^1 (1-s)a(s)N\,\mathrm{d}s \\
&\leqslant H_4
\end{aligned}$$

and therefore $\|Ax\| \leqslant \|x\|$.

Case 2. If f is unbounded, then we know from (A1) that there is H_4: $H_4 > \max\{2H_3, \frac{1}{\gamma}\widehat{H}_4\}$ such that

$$f(x) \leqslant f(H_4) \quad \text{for } 0 < x \leqslant H_4.$$

Then for $x \in K$ and $\|x\| = H_4$ we have

$$\begin{aligned}
Ax(t) &= -\int_0^t (t-s)a(s)f\big(x(s)\big)\,\mathrm{d}s - \frac{\alpha t}{1-\alpha\eta}\int_0^\eta (\eta-s)a(s)f\big(x(s)\big)\,\mathrm{d}s \\
&\quad + \frac{t}{1-\alpha\eta}\int_0^1 (1-s)a(s)f\big(x(s)\big)\,\mathrm{d}s \\
&\leqslant \frac{t}{1-\alpha\eta}\int_0^1 (1-s)a(s)f(H_4)\,\mathrm{d}s \\
&\leqslant \frac{1}{1-\alpha\eta}\int_0^1 (1-s)a(s)\lambda H_4\,\mathrm{d}s \\
&\leqslant H_4.
\end{aligned}$$

Therefore, in either case we may put

$$\Omega_4 = \big\{x \in C[0,1]:\ \|x\| < H_4\big\},$$

and for $x \in K \cap \partial\Omega_4$ we may have $\|Ax\| \leqslant \|x\|$. By the second part of Theorem 3.33, if follows that the BVP (3.80)–(3.81) has a positive solution. The proof of the theorem is completed. □

The previous results are taken from [69]. Theorem 3.38 was proved either for sub- or superlinear case. Therefore the following questions are natural:

- *Whether or not we can obtain similar conclusion, if* $f_0 = f_\infty = 0$ *or* $f_0 = f_\infty = \infty$;
- *Whether or not we can obtain similar conclusion, if* $f_0, f_\infty \notin \{0, \infty\}$.

Motivated by the results in [69], Liu in [57] established some simple criteria for the existence of positive solutions of the BVP (3.80)–(3.81), which gives a positive answer to the questions stated above. The key tool in his approach is the following fixed point index theorem [21].

THEOREM 3.39. *Let E be Banach space and $K \subset E$ be a cone in E. Let $r > 0$, and define $\Omega_r = \{x \in K\colon \|x\| < r\}$. Assume $A : \overline{\Omega}_r \to K$ is a completely continuous operator such that $Ax \neq x$ for $x \in \partial\Omega_r$.*

(i) *If $\|Ax\| \leqslant \|x\|$ for $x \in \partial\Omega_r$, then $i(A, \Omega_r, K) = 1$.*
(ii) *If $\|Ax\| \geqslant \|x\|$ for $x \in \partial\Omega_r$, then $i(A, \Omega_r, K) = 0$.*

In what follows, for the sake of convenience, set

$$\Lambda_1 = (1 - \alpha\eta)\left(\int_0^1 (1 - s)a(s)\,\mathrm{d}s\right)^{-1},$$

$$\Lambda_2 = (1 - \alpha\eta)\left(\eta\gamma \int_\eta^1 (1 - s)a(s)\,\mathrm{d}s\right)^{-1}.$$

THEOREM 3.40. *Assume that the following assumptions are satisfied*:

(H1) $f_0 = f_\infty = \infty$.
(H2) *There exist constants $\rho_1 > 0$ and $M_1 \in (0, \Lambda_1)$ such that $f(u) \leqslant M_1\rho_1$, $u \in [0, \rho_1]$.*

Then the BVP (3.80)–(3.81) *has at least two positive solutions x_1 and x_2 such that*

$$0 < \|x_1\| < \rho_1 < \|x_2\|.$$

PROOF. At first, in view of $f_0 = \infty$, then for any $M_* \in (\Lambda_2, \infty)$, there exist $\rho_* \in (0, \rho_1)$ such that

$$f(x) \geqslant M_* x, \quad 0 \leqslant x \leqslant \rho_*.$$

Set $\Omega_{\rho_*} = \{x \in K\colon \|x\| < \rho_*\}$. Since $x \in \partial\Omega_{\rho_*} \subset K$, we have $\min_{\eta \leqslant t \leqslant 1} x(t) \geqslant \gamma\|x\|$. Thus, for any $x \in \partial\Omega_{\rho_*}$, we have

$$Ax(\eta) = -\int_0^\eta (\eta - s)a(s)f\bigl(x(s)\bigr)\,\mathrm{d}s - \frac{\alpha\eta}{1 - \alpha\eta}\int_0^\eta (\eta - s)a(s)f\bigl(x(s)\bigr)\,\mathrm{d}s$$

$$
\begin{aligned}
&\quad + \frac{\eta}{1-\alpha\eta}\int_0^1 (1-s)a(s)f\bigl(x(s)\bigr)\,\mathrm{d}s \\
&= \frac{\eta}{1-\alpha\eta}\int_\eta^1 a(s)f\bigl(x(s)\bigr)\,\mathrm{d}s + \frac{1-\eta}{1-\alpha\eta}\int_0^\eta sa(s)f\bigl(x(s)\bigr)\,\mathrm{d}s \\
&\quad - \frac{\eta}{1-\alpha\eta}\int_\eta^1 sa(s)f\bigl(x(s)\bigr)\,\mathrm{d}s \\
&\geqslant \frac{\eta}{1-\alpha\eta}\int_\eta^1 (1-s)a(s)f\bigl(x(s)\bigr)\,\mathrm{d}s \\
&\geqslant \frac{\eta}{1-\alpha\eta}\int_\eta^1 (1-s)a(s)M_* x(s)\,\mathrm{d}s \\
&\geqslant \frac{\gamma\eta M_*}{1-\alpha\eta}\int_\eta^1 (1-s)a(s)\|x\|\,\mathrm{d}s \\
&> \|x\|,
\end{aligned}
$$

which yields

$$
\|Ax\| > \|x\|, \quad \text{for } y \in \partial\Omega_{\rho_*}.
$$

Hence, Theorem 3.39 implies $i(A, \Omega_{\rho_*}, K) = 0$.

Next, since $f_\infty = \infty$, then for any $M^* \in (\Lambda_2, \infty)$, then there exist $\rho^* > \rho_1$ such that

$$
f(x) \geqslant M^* x, \quad 0 \leqslant x \leqslant \gamma\rho^*.
$$

Set $\Omega_{\rho^*} = \{x \in K\colon \|x\| < \rho^*\}$ for $x \in \partial\Omega_{\rho^*}$. Since $x \in K$, we have $\min_{\eta \leqslant t \leqslant 1} x(t) \geqslant \gamma\|x\| = \gamma\rho^*$. Thus, for any $x \in \partial\Omega_{\rho^*}$, we have

$$
\begin{aligned}
Ax(\eta) &= -\int_0^\eta (\eta-s)a(s)f\bigl(x(s)\bigr)\,\mathrm{d}s - \frac{\alpha\eta}{1-\alpha\eta}\int_0^\eta (\eta-s)a(s)f\bigl(x(s)\bigr)\,\mathrm{d}s \\
&\quad + \frac{\eta}{1-\alpha\eta}\int_0^1 (1-s)a(s)f\bigl(x(s)\bigr)\,\mathrm{d}s \\
&\geqslant \frac{\eta}{1-\alpha\eta}\int_\eta^1 (1-s)a(s)f\bigl(x(s)\bigr)\,\mathrm{d}s \\
&\geqslant \frac{\eta}{1-\alpha\eta}\int_\eta^1 (1-s)a(s)M^* x(s)\,\mathrm{d}s \\
&\geqslant \frac{\gamma\eta M^*}{1-\alpha\eta}\int_\eta^1 (1-s)a(s)\|x\|\,\mathrm{d}s \\
&> \|x\|,
\end{aligned}
$$

which implies

$$\|Ax\| > \|x\|, \quad \text{for } y \in \partial\Omega_{\rho^*}.$$

Hence, Theorem 3.39 yields $i(A, \Omega_{\rho_*}, K) = 0$.

Finally, set $\Omega_{\rho_1} = \{x \in K\colon \|x\| < \rho_1\}$. For any $x \in \partial\Omega_{\rho_1}$ we obtain

$$\begin{aligned} Ax(t) &\leqslant \frac{t}{1-\alpha\eta}\int_0^1 (1-s)a(s)f\bigl(x(s)\bigr)\,\mathrm{d}s \\ &\leqslant \frac{M_1\rho_1}{1-\alpha\eta}\int_0^1 (1-s)a(s)\,\mathrm{d}s \\ &< \rho_1 = \|x\|, \end{aligned}$$

which yields

$$\|Ax\| < \|x\|, \quad \text{for } y \in \partial\Omega_{\rho_1}.$$

Thus, Theorem 3.39 again shows that $i(A, \Omega_{\rho_1}, K) = 1$.

Hence, since $\rho_* < \rho_1 < \rho^*$ it follows from the additivity of the fixed point index that

$$i\bigl(A, \Omega_{\rho_1} \setminus \overline{\Omega}_{\rho_*}, K\bigr) = 1, \qquad i\bigl(A, \Omega_{\rho^*} \setminus \overline{\Omega}_{\rho_1}, K\bigr) = -1.$$

Thus, A has a fixed point x_1 in $\Omega_{\rho_1} \setminus \overline{\Omega}_{\rho_*}$, and a fixed point x_2 in $\Omega_{\rho^*} \setminus \overline{\Omega}_{\rho_1}$. Both are positive solutions, $0 < \|x_1\| < \rho_1 < \|x_2\|$, and the proof of the theorem is complete. □

THEOREM 3.41. *Assume that the following assumptions are satisfied*:

(H3) $f_0 = f_\infty = 0$.

(H4) *There exist constants* $\rho_2 > 0$ *and* $M_2 \in (\Lambda_2, \infty)$ *such that* $f(u) \geqslant M_2\rho_2$, $u \in [\gamma\rho_2, \rho_2]$.

Then the BVP (3.80)–(3.81) *has at least two positive solutions* x_1 *and* x_2 *such that*

$$0 < \|x_1\| < \rho_2 < \|x_2\|.$$

PROOF. First, since $f_0 = 0$, for any $\varepsilon \in (0, \Lambda_1)$, there exists $\rho_* \in (0, \rho_2)$ such that

$$f(x) \leqslant \varepsilon x, \quad \text{for } x \in [0, \rho_*].$$

Setting $\Omega_{\rho_*} = \{x \in K\colon \|x\| < \rho_*\}$ for any $x \in \partial\Omega_{\rho_*}$, we get

$$\begin{aligned} Ax(t) &\leqslant \frac{t}{1-\alpha\eta}\int_0^1 (1-s)a(s)f\bigl(x(s)\bigr)\,\mathrm{d}s \\ &\leqslant \frac{\varepsilon\rho_*}{1-\alpha\eta}\int_0^1 (1-s)a(s)\,\mathrm{d}s < \rho_* = \|x\|, \end{aligned}$$

which yields

$$\|Ax\| < \|x\|, \quad \text{for } x \in \partial\Omega_{\rho_*}.$$

Thus Theorem 3.39 implies $i(A, \Omega_{\rho_*}, K) = 1$.

Second, in view $f_\infty = 0$, then for any $\varepsilon \in (0, \Lambda_1)$, there exists $\rho_0 > \rho_2$ such that

$$f(x) \leqslant \varepsilon x, \quad \text{for } x \in [\rho_0, \infty),$$

and we consider two cases.

Case (i). Suppose that f is unbounded; then from $f \in C([0,\infty),[0,\infty))$, we know that there is $\rho^* > \rho_0$ such that $f(x) \leqslant f(\rho^*)$, for $x \in [0, \rho^*]$. Since $\rho^* > \rho_0$, one has $f(x) \leqslant f(\rho^*) \leqslant \varepsilon\rho^*$, for $x \in [0, \rho^*]$. For $x \in K$, $\|x\| = \rho^*$ we obtain

$$\begin{aligned} Ax(t) &\leqslant \frac{t}{1-\alpha\eta}\int_0^1 (1-s)a(s)f\big(x(s)\big)\,\mathrm{d}s \\ &\leqslant \frac{\varepsilon\rho_*}{1-\alpha\eta}\int_0^1 (1-s)a(s)\,\mathrm{d}s < \rho_* = \|x\|. \end{aligned}$$

Case (ii). Suppose that f is bounded, say $f(x) \leqslant L$. Taking $\rho^* \geqslant \max\{L/\varepsilon, \rho_2\}$, for $x \in K$, $\|x\| = \rho^*$ one has

$$\begin{aligned} Ax(t) &\leqslant \frac{t}{1-\alpha\eta}\int_0^1 (1-s)a(s)f\big(x(s)\big)\,\mathrm{d}s \\ &\leqslant \frac{L}{1-\alpha\eta}\int_0^1 (1-s)a(s)\,\mathrm{d}s < \rho_* = \|x\|. \end{aligned}$$

Hence, in either case, we always may set $\Omega_{\rho^*} = \{x \in K\colon \|x\| < \rho^*\}$ such that

$$\|Ax\| < \|x\|, \quad \text{for } x \in \partial\Omega_{\rho_*}.$$

Thus Theorem 3.39 implies $i(A, \Omega_{\rho_*}, K) = 1$.

Finally set $\Omega_{\rho_2} = \{x \in K\colon \|x\| < \rho_2\}$, for $x \in \partial\Omega_{\rho_2}$, since $x \in K$, $\min_{\eta\leqslant t\leqslant 1} x(t) \geqslant \gamma\|x\| = \gamma\rho_2$, and hence we can get

$$\begin{aligned} Ax(\eta) &\geqslant \frac{\eta}{1-\alpha\eta}\int_\eta^1 (1-s)a(s)f\big(x(s)\big)\,\mathrm{d}s \\ &\geqslant \frac{\gamma\eta M_2}{1-\alpha\eta}\rho_2\int_\eta^1 (1-s)a(s)\,\mathrm{d}s > \rho_2 = \|x\|, \end{aligned}$$

which yields

$$\|Ax\| > \|x\|, \quad \text{for } x \in \partial\Omega_{\rho_2}.$$

Thus Theorem 3.39 implies $i(A, \Omega_{\rho_2}, K) = 0$.

Hence, since $\rho_* < \rho_2 < \rho^*$ it follows from the additivity of the fixed point index that

$$i\big(A, \Omega_{\rho_2} \setminus \overline{\Omega}_{\rho_*}, K\big) = -1, \qquad i\big(A, \Omega_{\rho^*} \setminus \overline{\Omega}_{\rho_2}, K\big) = 1.$$

Thus, A has a fixed point x_1 in $\Omega_{\rho_2} \setminus \overline{\Omega}_{\rho_*}$, and a fixed point x_2 in $\Omega_{\rho^*} \setminus \overline{\Omega}_{\rho_2}$. Both are positive solutions, $0 < \|x_1\| < \rho_2 < \|x_2\|$, and the proof of the theorem is complete. □

For the case when $f_0, f_\infty \notin \{0, \infty\}$ we have the following

THEOREM 3.42. *Suppose that* (H2) *and* (H4) *hold and that* $\rho_1 \neq \rho_2$. *Then the BVP* (3.80)–(3.81) *has at least one positive solution* x *satisfying* $\rho_1 < \|x\| < \rho_2$ *or* $\rho_2 < \|x\| < \rho_1$.

Theorems 3.40–3.42 were taken from [57]. A method to study the existence of positive solutions of some three-point BVPs is to write the BVP as an equivalent Hammerstein integral equation of the form

$$x(t) = \int_0^1 k(t,s)a(s)f\big(x(s)\big)\,\mathrm{d}s \equiv Tx(t),$$

and seek fixed points of T in the cone of positive functions in the space $C[0,1]$. We use the fixed point index for compact maps, which is based on Leray–Schauder degree theory, and use a well-known nonzero fixed point theorem in order to prove that T has a positive fixed point.

We apply this method for the BVP (3.80)–(3.81) using the cone defined by

$$K = \big\{x \in C[0,1]\colon\ x \geqslant 0,\ \min\big\{x(t)\colon\ a \leqslant t \leqslant b\big\} \geqslant c\|x\|\big\},$$

and the following kernel (Green's function) in the Hammerstein integral operator

$$k(t,s) = \frac{1}{1-\alpha\eta}t(1-s) - \begin{cases} \dfrac{\alpha t}{1-\alpha\eta}(\eta - s), & s \leqslant \eta \\ 0, & s > \eta \end{cases} - \begin{cases} t-s, & s \leqslant t \\ 0, & s > t. \end{cases}$$

Let $a, b \in (0,1]$ and suppose that $\int_a^b a(t)\,\mathrm{d}t > 0$. We are able to find upper and lower bounds for $k(t,s)$ with s fixed, of the same type. We have the same freedom in choosing the numbers a and b. Let us find the upper and lower bounds for the BVP (3.80)–(3.81). We have to exhibit $\Phi(s)$, a subinterval $[a,b] \subset [0,1]$ and a constant $c \in (0,1]$ such that

$$\begin{aligned} &k(t,s) \leqslant \Phi(s), && \text{for every } t, s \in [0,1], \\ &k(t,s) \geqslant c\Phi(s), && \text{for every } s \in [0,1], t \in [a,b]. \end{aligned}$$

3.9.1. *Upper bounds* We shall show that we may take $\Phi(s) = \max\{1, \alpha\}\frac{s(1-s)}{1-\alpha\eta}$. (In this case $\alpha\eta < 1$ but it is possible to have $\alpha > 1$.)

Case 1: $s > \eta$. $t < s$ is simple so consider $t \geqslant s$. Then $k(t,s) = s + \frac{(\alpha\eta - s)t}{1-\alpha\eta}$. If also $s \geqslant \alpha\eta$ then it is a decreasing function of t so the maximum occurs when $t = s$ and

$$k(t,s) \leqslant \frac{s - s\alpha\eta + s(\alpha\eta - s)}{1-\alpha\eta} = \frac{s(1-s)}{1-\alpha\eta} \leqslant \Phi(s).$$

If $s < \alpha\eta$ (which can happen only if $\alpha > 1$) the maximum occurs at $t = 1$ and then

$$k(t,s) \leqslant \frac{\alpha\eta(1-s)}{1-\alpha\eta} < \alpha\frac{s(1-s)}{1-\alpha\eta} = \Phi(s).$$

Case 2: $s \leqslant \eta$. For $t \leqslant s$ we clearly have $k(t,s) \leqslant \frac{s(1-s)}{1-\alpha\eta} \leqslant \Phi(s)$. So consider $t \geqslant s$. Then $k(t,s) = s + \frac{st(\alpha-1)}{1-\alpha\eta}$. For $\alpha > 1$ the maximum occurs when $t = 1$ and then

$$k(t,s) \leqslant \frac{\alpha s(1-\eta)}{1-\alpha\eta} \leqslant \alpha\frac{s(1-s)}{1-\alpha\eta} = \Phi(s),$$

using $s \leqslant \eta$. For $\alpha \leqslant 1$ the maximum occurs when $t = s$ and then

$$k(t,s) = \frac{\alpha s(s-\eta) + s(1-s)}{1-\alpha\eta} \leqslant \frac{s(1-s)}{1-\alpha\eta} = \Phi(s).$$

3.9.2. *Lower bounds* We will show that we may take arbitrary $a > 0$ and $b \leqslant 1$.

Case 1: $s > \eta$. For $t < s$, $k(t,s) = \frac{t(1-s)}{1-\alpha\eta} \geqslant a\frac{s(1-s)}{1-\alpha\eta} \geqslant a\eta\Phi(s)$. For $t \geqslant s$, $k(t,s) = s - \frac{t(s-\alpha\eta)}{1-\alpha\eta}$. If $s > \alpha\eta$ then the minimum occurs when $t = 1$ so

$$k(t,s) \geqslant \frac{\alpha\eta(1-s)}{1-\alpha\eta} \geqslant \alpha\eta\frac{s(1-s)}{1-\alpha\eta} = \begin{cases} \alpha\eta\Phi(s), & \alpha \leqslant 1, \\ \eta\Phi(s), & \alpha > 1. \end{cases}$$

If $s \leqslant \alpha\eta$ (only possible if $\alpha > 1$) the minimum is at $t = s$ and

$$k(t,s) \geqslant \frac{s(1-s)}{1-\alpha\eta} \geqslant \eta\Phi(s).$$

Case 2: $s \leqslant \eta$. First suppose $a \leqslant t \leqslant s$. (This case cannot occur if $\alpha \geqslant \eta$.) Then $k(t,s) = \frac{t[1-\alpha\eta+(\alpha-1)s]}{1-\alpha\eta}$. For $\alpha < 1$ we have $[1-\alpha\eta+(\alpha-1)s] \geqslant 1-\alpha\eta+(\alpha-1)\eta = 1-\eta$ so $k(t,s)$ is increasing in t and has a minimum when $t = a$. Thus

$$k(t,s) \geqslant \frac{a}{1-\alpha\eta}[1-\eta] \geqslant 4a(1-\eta)\Phi(s),$$

since $s(1-s) \leqslant 1/4$. Note that $4a(1-\eta) < 1$ since $\alpha < \eta$.

For $\alpha > 1$, $k(t,s)$ is clearly increasing so we have

$$k(t,s) \geqslant \frac{a}{1-\alpha\eta}\big[1-\alpha\eta+(\alpha-1)s\big] \geqslant \frac{a}{1-\alpha\eta}[1-\alpha\eta] \geqslant \frac{4(1-\alpha\eta)a}{\alpha}\Phi(s).$$

Note that $\frac{4(1-\alpha\eta)a}{\alpha} = \frac{4a\alpha\eta(1-\alpha\eta)}{\alpha^2\eta} < \frac{1}{\alpha^2} < 1$ since $\alpha < \eta$.

Now suppose that $t \geqslant s$. Then $k(t,s) = s + \frac{t(\alpha-1)s}{1-\alpha\eta}$. For $\alpha \leqslant 1$ the minimum occurs when $t = 1$ and then

$$k(t,s) \geqslant \frac{\alpha(1-\eta)s}{1-\alpha\eta} \geqslant \alpha(1-\eta)\Phi(s).$$

For $\alpha > 1$ the minimum occurs either at $t = s$ or $t = a$ but in both cases

$$k(t,s) \geqslant s \geqslant \frac{1-\alpha\eta}{\alpha}\Phi(s) \geqslant \eta(1-\alpha\eta)\Phi(s).$$

The conclusion is that we may take

$$c = \begin{cases} \min\bigl\{a, \alpha\eta, 4a(1-\eta), \alpha(1-\eta)\bigr\}, & \alpha < 1, \\ \min\bigl\{a\eta, 4a(1-\alpha\eta), \eta(1-\alpha\eta)\bigr\}, & \alpha \geqslant 1. \end{cases}$$

Hence we have:

THEOREM 3.43. *Let $a, b \in (0,1]$ and suppose that $\int_a^b a(t)\,\mathrm{d}t > 0$. Let c as defined above and*

$$m = \left(\max_{0\leqslant t\leqslant 1} \int_0^1 k(t,s)a(s)\,\mathrm{d}s\right)^{-1}, \qquad M = \left(\min_{0\leqslant t\leqslant 1} \int_a^b k(t,s)a(s)\,\mathrm{d}s\right)^{-1}.$$

Then for $0 < \alpha\eta < 1$ the BVP (3.80)–(3.81) has at least one positive solution if either

$$\text{(h1)} \quad 0 \leqslant \limsup_{x\to 0} \frac{f(x)}{x} < m \quad \textit{and} \quad M < \liminf_{x\to\infty} \frac{f(x)}{x} \leqslant \infty,$$

or

$$\text{(h2)} \quad 0 \leqslant \limsup_{x\to \infty} \frac{f(x)}{x} < m \quad \textit{and} \quad M < \liminf_{x\to 0} \frac{f(x)}{x} \leqslant \infty,$$

and has two positive solutions if there is $\rho > 0$ such that either

$$\text{(E1)} \quad \begin{cases} 0 \leqslant \limsup\limits_{x\to 0} \dfrac{f(x)}{x} < m, \\ \min\left\{\dfrac{f(x)}{\rho}\colon x \in [c\rho, \rho]\right\} \geqslant cM,\ x \neq Tx \quad \textit{for } x \in \partial\Omega_\rho, \quad \textit{and} \\ 0 \leqslant \limsup\limits_{x\to \infty} \dfrac{f(x)}{x} < m, \end{cases}$$

or

$$\text{(E2)}\quad \begin{cases} M < \limsup\limits_{x\to 0} \dfrac{f(x)}{x} \leqslant \infty, \\ \max\left\{\dfrac{f(x)}{\rho}\colon\ x \in [0,\rho]\right\} \leqslant m,\ x \neq Tx \quad \textit{for } x \in \partial K_\rho, \quad \textit{and} \\ M < \limsup\limits_{x\to \infty} \dfrac{f(x)}{x} \leqslant \infty, \end{cases}$$

where

$$\Omega_\rho = \Bigl\{x \in K\colon\ c\|x\| \leqslant \min_{a\leqslant t\leqslant b} x(t) < c\rho\Bigr\}, \qquad K_r = \bigl\{x \in K\colon\ \|x\| < \rho\bigr\}$$

and K is a closed convex set in a Banach space.

Theorem 3.43 is taken from Webb [92]. Similar results are given by Infante [45] who proved existence of eigenvalues of some nonlocal BVP, including nonlocal boundary conditions other than (3.81), as

(a) $x'(0) = 0, \alpha x'(\eta) = x(1), 0 < \eta < 1,$
(b) $x(0) = 0, \alpha x'(\eta) = x(1), 0 < \eta < 1,$
(c) $x'(0) = 0, \alpha x(\eta) = x(1), 0 < \eta < 1.$

Infante and Webb [47] obtained more general results for existence of positive solutions of some m-point BVPs in the case when all the parameters occurring in the boundary conditions are not positive and the nonlinear term allow more general behaviour than being either sub- or superlinear. Two four-points BVPs are studied in details in [47].

Also interesting results were given for the following three-point BVP

$$x'' + a(t)f(x) = 0, \quad t \in (0,1), \tag{3.84}$$

$$x'(0) = 0, \qquad \alpha x(\eta) = x(1), \tag{3.85}$$

where $0 < \eta < 1$, $0 < \alpha < 1$ by Liu in [56]. By applying Krasnosel'skii's fixed point theorem he proved existence

- of single positive solution under $f_0 = 0, f_\infty = \infty$ or $f_0 = \infty, f_\infty = 0$,
- of two positive solution under $f_0 = f_\infty = \infty$ or $f_0 = f_\infty = 0$,
- of positive solutions under $f_0, f_\infty \notin \{0, \infty\}$.

In [56] some interesting examples were given to demonstrate the results.

A more general three-point BVP was studied by Ma and Wang. In [79] they studied the existence of positive solutions of the following BVP

$$x''(t) + a(t)x'(t) + b(t)x(t) + h(t)f(x) = 0, \quad t \in (0,1), \tag{3.86}$$

$$x(0) = 0, \qquad x(1) = \alpha x(\eta), \tag{3.87}$$

where $f \in C([0,1],[0,\infty))$, $h \in C([0,1],[0,\infty))$ and there exists $x_0 \in [0,1]$ such that $h(x_0) > 0$, and $a \in C[0,1]$, $b \in C([0,1],(-\infty,0))$. Under these assumptions they proved the existence of at least one positive solution of the BVP (3.86)–(3.87) either in superlinear or sublinear case, by applying the Krasnosel'skii's fixed point theorem in cones.

If in the BVP (3.80)–(3.81) the boundary condition (3.81) is nonhomogeneous, i.e.

$$x(0) = 0, \qquad x(1) - \alpha x(\eta) = b, \tag{3.88}$$

Ma in [78], by using Schauder's fixed point theorem, proved in the superlinear case that, if (A1) and (A2) of Theorem 3.38 hold, then there exists a positive number b^* such that (3.80), (3.88) has at least one positive solution for b: $0 < b < b^*$ and no solution for $b > b^*$. This result was improved and complemented by Zhang and Wang in [95], where they studied the BVP (3.80), (3.88) under the following conditions:

(H1) $\alpha \in (0, 1/\eta)$, $\eta \in (0, 1)$;

(H2) $a(t)$ is a nonnegative measurable function defined on $(0, 1)$ and

$$0 \leqslant \int_0^\eta s a(s)\,\mathrm{d}s < +\infty, \qquad 0 < \int_\eta^1 (1-s)a(s)\,\mathrm{d}s < +\infty;$$

(H3) $f : [0, \infty) \to [0, \infty)$ is continuous;

(H3*) $f : [0, \infty) \to [0, \infty)$ is locally Lipschitz continuous;

(H4) $\limsup_{u\to+\infty} \frac{f(u)}{u} < \delta$;

(H5) $\liminf_{u\to+\infty} \frac{f(u)}{u} > M$;

(H6) $\lim_{u\to 0+} \frac{f(u)}{u} < \delta$,

where δ, M are suitable defined constants, and proved that:

- the BVP (3.80), (3.88) has a positive solution for all $b > 0$ if (H1)–(H4) hold;
- there exists a positive number b^* such that (3.80), (3.88) has at least one positive solution for b: $0 < b < b^*$ and no solution for $b > b^*$ if (H1)–(H3), (H5) and (H6) hold;
- there exists a positive number b^* such that (3.80), (3.88) has at least two solution for b: $0 < b < b^*$, at least one for $b = b^*$, none for $b > b^*$ if (H1), (H2), (H3*), (H5) and (H6) hold.

We remark that (H2) allows $a(t)$ to be singular at $t = 0$ and/or $t = 1$, and (H5) and (H6) allow but not require the nonlinearity $f(x)$ to be superlinear at zero and infinity.

Now, we consider the following three-point nonlinear second-order BVP

$$x''(t) + \lambda a(t) f\bigl(x(t)\bigr) = 0, \quad t \in (0, 1), \tag{3.89}$$

$$x(0) = 0, \qquad \alpha x(\eta) = x(1), \tag{3.90}$$

where $0 < \eta < 1$. For this problem, an open interval of eigenvalues is determined, which in return, imply the existence of a positive solution of (3.89)–(3.90) by appealing to Krasnosel'skii's fixed point theorem.

For the sake of simplicity, we let

$$A = (1-\alpha\eta)^{-1} \int_0^1 (1-\eta)a(s)\,\mathrm{d}s, \qquad B = \eta(1-\alpha\eta)^{-1} \int_0^1 (1-\eta)a(s)\,\mathrm{d}s.$$

THEOREM 3.44. *Assume that*

(A1) $f \in C([0,\infty),[0,\infty))$;

(A2) $a \in C([0,1],[0,\infty))$ *and does not vanish identically on any subinterval.*

(A3) $\lim_{x\to 0+} \frac{f(x)}{x} = l$ *with* $0 < l < \infty$.

(A4) $\lim_{x\to \infty} \frac{f(x)}{x} = L$ *with* $0 < L < \infty$.

Then, for each λ *satisfying either*

(i) $\frac{1}{\gamma BL} < \lambda < \frac{1}{Al}$

or

(ii) $\frac{1}{\gamma Bl} < \lambda < \frac{1}{AL}$

the BVP (3.89)–(3.90) *has at least one positive solution.*

PROOF. Let λ given as in (i), and choose $\epsilon > 0$ such that

$$\frac{1}{\gamma B(L-\epsilon)} \leqslant \lambda \leqslant \frac{1}{A(l+\epsilon)}.$$

Consider also the cone K and the operator A defined in the proof of Theorem 3.38. By (A3), there exists $H_1 > 0$ such that $f(x) \leqslant (l+\epsilon)x$, for $0 < x \leqslant H_1$. So, choosing $x \in K$ with $\|x\| = H_1$, we have

$$\begin{aligned}
Ax(t) &= \lambda \frac{t}{1-\alpha\eta} \int_0^1 (1-s)a(s) f\bigl(x(s)\bigr)\,\mathrm{d}s \\
&\leqslant \lambda \frac{t}{1-\alpha\eta} \int_0^1 (1-s)a(s)(l+\epsilon)x(s)\,\mathrm{d}s \\
&\leqslant \lambda \frac{1}{1-\alpha\eta} \int_0^1 (1-s)a(s)(l+\epsilon)\|x\|\,\mathrm{d}s \\
&\leqslant \lambda \frac{1}{1-\alpha\eta} \int_0^1 (1-s)a(s)(l+\epsilon)H_1\,\mathrm{d}s \\
&\leqslant \lambda A(l+\epsilon)\|x\| \leqslant \|x\|.
\end{aligned}$$

Consequently, $\|Ax\| \leqslant \|x\|$. So, if we set

$$\Omega_1 = \bigl\{x \in C[0,1]\colon\ \|x\| < H_1\bigr\},$$

then $\|Ax\| \leqslant \|x\|$, for $x \in K \cap \partial\Omega_1$.

Next we construct the set Ω_2. Considering (A4) there exists $\overline{H}_2$ such that $f(x) \geqslant (L-\epsilon)x$, for $x \geqslant \overline{H}_2$. Let $H_2 = \max\{2H_1, \frac{\widehat{H}_2}{\gamma}\}$ and $\Omega_2 = \{x \in C[0,1]\colon\ \|x\| < H_2\}$, then $x \in K$ and $\|x\| = H_2$ implies

$$\min_{\eta\leqslant t\leqslant 1} x(t) \geqslant \gamma\|x\| \geqslant \widehat{H}_2,$$

and so

$$\begin{aligned}
Ax(\eta) &= \lambda\frac{\eta}{1-\alpha\eta}\int_\eta^1 (1-s)a(s)f\bigl(x(s)\bigr)\,\mathrm{d}s\\
&\geqslant \lambda\frac{\eta}{1-\alpha\eta}\int_\eta^1 (1-s)a(s)(L-\epsilon)x(s)\,\mathrm{d}s\\
&\geqslant \lambda\frac{\eta}{1-\alpha\eta}\int_\eta^1 (1-s)a(s)(L-\epsilon)\gamma\|x\|\,\mathrm{d}s\\
&= \lambda\frac{\gamma\eta}{1-\alpha\eta}\int_\eta^1 (1-s)a(s)(L-\epsilon)H_2\,\mathrm{d}s\\
&\geqslant \lambda B\gamma(L-\epsilon)\|x\|\\
&= \|x\|.
\end{aligned}$$

Hence, for $x \in K \cap \partial\Omega_2$,

$$\|Ax\| \geqslant \|x\|.$$

Therefore, by the first part of Theorem 3.33, it follows that A has a fixed point in $K \cap (\overline{\Omega}_2 \setminus \Omega_1)$, completing the proof in case (i).

Consider now the case (ii). Let λ given as in (ii) and choose $\epsilon > 0$ such that

$$\frac{1}{\gamma B(l-\epsilon)} \leqslant \lambda \leqslant \frac{1}{A(L+\epsilon)}.$$

We omit the rest of the proof, since it is similar to that of Theorem 3.38. □

Theorem 3.44 is taken from Raffoul [89]. He proved also that:

- if (A1), (A2), (A4) hold and $\lim_{x\to 0+}\frac{f(x)}{x} = \infty$ then the BVP (3.89)–(3.90) has at least one positive solution for each λ satisfying $0 < \lambda < \frac{1}{AL}$;
- if (A1), (A2), (A3) hold and $\lim_{x\to\infty}\frac{f(x)}{x} = \infty$ then the BVP (3.89)–(3.90) has at least one positive solution for each λ satisfying $0 < \lambda < \frac{1}{Al}$.

Other existence and multiplicities of positive solutions for the BVP (3.89)–(3.90) were proved by Ma in [70] by using fixed point index theory and the method of upper and lower solutions. He proved in [70] the following result.

THEOREM 3.45. *Assume that*:

(A1) λ *is a positive parameter*; $\eta \in (0,1)$ *and* $\alpha\eta < 1$.

(A2) $a : [0,1] \to [0,\infty)$ *is continuous and does not vanish identically on any subset of positive measure*.

(A3) $\lim_{x\to\infty}\frac{f(x)}{x} = \infty$.

Then there exists a positive λ^* *such that the BVP* (3.89)–(3.90) *has at least two positive solutions for* $0 < \lambda < \lambda^*$, *at least one positive solution for* $\lambda = \lambda^*$, *and no positive solutions for* $\lambda > \lambda^*$.

Interesting results on the existence of multiple positive solutions for three-point BVP can be obtained by using the Leggett–Williams fixed point theorem. We will give such a result proving the existence of triple positive solutions of the following BVP

$$x'' + f(t, x) = 0, \quad t \in (0, 1), \tag{3.91}$$

$$x(0) = 0, \qquad x(1) = \alpha x(\eta). \tag{3.92}$$

In this approach, we do not need the assumption that f is sublinear or superlinear, which was required in Theorem 3.38.

For convenience of the reader, we present here the necessary definitions from cone theory in Banach spaces.

DEFINITION 3.46. Let E be a Banach space over $\mathbb{R}$. A nonempty, closed set $P \subset E$ is said to be a cone provided that

(a) $\alpha u + \beta v \in P$ for all $u, v \in P$ and all $\alpha, \beta \geqslant 0$ and
(b) $u, -u \in P$ implies $u = 0$.

If $P \subset E$ is a cone, we denote the order induced by P on E by $\leqslant$. For $u, v \in P$, we write $u \leqslant v$ if and only if $v - u \in P$.

DEFINITION 3.47. The map ψ is said to be a nonnegative continuous concave functional on P provided $\psi : P \to [0, \infty)$ is continuous and

$$\psi\big(\lambda x + (1 - \lambda)y\big) \geqslant \lambda\psi(x) + (1 - \lambda)\psi(y)$$

for all $x, y \in P$ and $\lambda \in [0, 1]$.

Let $0 < a < b$ be given and let ψ be a nonnegative continuous concave functional on the cone P. Define the convex sets P_r and $P(\psi, a, b)$ by

$$P_r = \big\{y \in P\colon \ \|y\| < r\big\}$$

and

$$P(\psi, a, b) = \big\{y \in P\colon \ a \leqslant \psi(y), \ \text{and } \|y\| \leqslant b\big\}.$$

Our consideration is based on the following fixed point theorem given by Leggett and Williams in 1979 [55] (see also Guo and Lakshmikantham [21]).

THEOREM 3.48 (Legget–Williams fixed-point theorem). *Let* $T : \overline{P}_c \to \overline{P}_c$ *be a completely continuous operator and let* ψ *be a nonnegative continuous concave functional* *on P such that $\psi(y) \leqslant \|y\|$ for $y \in \overline{P}_c$. Suppose that there exist $0 < a < b < d \leqslant c$ such that*

(C1) $\{y \in P(\psi, b, d)\colon \psi(y) > b\} \neq \emptyset$ *and* $\psi(Ty) > b$ *for all* $y \in P(\psi, b, d)$;

(C2) $\|Ty\| < a$ *for all* $\|y\| \leqslant a$, *and*

(C3) $\psi(Ty) > b$ *for* $y \in P(\psi, b, c)$ *with* $\|Ty\| > d$.

Then T has at least three fixed points y_1, y_2, and y_3 such that $\|y_1\| < a$, $b < \psi(y_2)$ and $\|y_3\| > a$ with $\psi(y_3) < b$.

THEOREM 3.49. *Assume that $\eta \in (0,1)$, $\alpha > 0$ and $\alpha\eta < 1$. Assume that*:

(A1) $f:[0,1] \times [0,\infty) \to [0,\infty)$ *is continuous and* $f(t,\cdot)$ *does not vanish identically on any subset of* $[0,1]$ *with positive measure.*

Suppose also that there exist constants $0 < a < b < b/\gamma \leqslant c$ such that

(D1) $f(t,x) < ma$, *for* $0 \leqslant t \leqslant 1$, $0 \leqslant x \leqslant a$,

(D2) $f(t,x) \geqslant b/\delta$, *for* $\eta \leqslant t \leqslant 1$, $b \leqslant x \leqslant b/\gamma$,

(D3) $f(t,x) \leqslant mc$, *for* $0 \leqslant t \leqslant 1$, $0 \leqslant x \leqslant c$,

where

$$m = \left(\frac{2 - \alpha\eta + \alpha\eta^2}{2(1-\alpha\eta)}\right)^{-1}, \qquad \delta = \min\left\{\frac{\alpha\eta(1-\eta)^2}{2(1-\alpha\eta)}, \frac{\eta(1-\eta)^2}{2(1-\alpha\eta)}\right\},$$

and γ is defined in Lemma 3.37. *Then the BVP* (3.91)–(3.92) *has at least three positive solutions x_1, x_2 and x_3 satisfying $\|x_1\| < a, b < \psi(x_2)$ and $\|x_3\| > a$ with $\psi(x_3) < b$.*

PROOF. Let $E = C[0,1]$ be endowed with the maximum norm, $\|x\| = \max_{0 \leqslant t \leqslant 1} |x(t)|$, and the ordering $x \leqslant y$ if $x(t) \leqslant y(t)$ for all $t \in [0,1]$. From the fact $x''(t) = -f(t,x) \leqslant 0$, we know that $x(t)$ is concave on $[0,1]$. So, define the cone $P \subset E$ by

$$P = \bigl\{x \in E\colon x \text{ is concave and nonnegative valued on } [0,1]\bigr\}.$$

Finally, let the nonnegative concave functional $\psi : P \to [0,\infty)$ be defined by

$$\psi(x) = \min_{\eta \leqslant t \leqslant 1} x(t), \quad x \in P.$$

We notice that for each $x \in P$, $\psi(x) \leqslant \|x\|$. Define an operator $T : P \to E$ by

$$Tx(t) = -\int_0^t (t-s) f\bigl(s, x(s)\bigr)\,\mathrm{d}s - \frac{\alpha t}{1-\alpha\eta}\int_0^\eta (\eta - s) f\bigl(s, x(s)\bigr)\,\mathrm{d}s + \frac{t}{1-\alpha\eta}\int_0^1 (1-s) f\bigl(s, x(s)\bigr)\,\mathrm{d}s.$$

We note that, if $x \in P$ then $Tx(t) \geqslant 0$, $0 \leqslant t \leqslant 1$. In view of $(Tx)''(t) = -f(t, x(t)) \leqslant 0$, $0 \leqslant t \leqslant 1$, we see that $Tx \in P$; that is to say that $T : P \to P$. Also T is completely continuous.

We now show that all the conditions of Theorem 3.48 are satisfied. Now if $x \in \overline{P}_c$, then $\|x\| \leqslant c$ and (D3) implies $f(t,x(t)) \leqslant mc$, $0 \leqslant t \leqslant 1$. Consequently,

$$\begin{aligned}
\|Tx\| &= \max_{0\leqslant t\leqslant 1} -\int_0^t (t-s) f\bigl(s,x(s)\bigr)\,\mathrm{d}s - \frac{\alpha t}{1-\alpha\eta}\int_0^\eta (\eta-s) f\bigl(s,x(s)\bigr)\,\mathrm{d}s \\
&\quad + \frac{t}{1-\alpha\eta}\int_0^1 (1-s) f\bigl(s,x(s)\bigr)\,\mathrm{d}s \\
&\leqslant \max_{0\leqslant t\leqslant 1}\int_0^t (t-s) f\bigl(s,x(s)\bigr)\,\mathrm{d}s + \frac{\alpha t}{1-\alpha\eta}\int_0^\eta (\eta-s) f\bigl(s,x(s)\bigr)\,\mathrm{d}s \\
&\quad + \frac{t}{1-\alpha\eta}\int_0^1 (1-s) f\bigl(s,x(s)\bigr)\,\mathrm{d}s \\
&\leqslant \max_{0\leqslant t\leqslant 1}\biggl(\int_0^t (t-s)\,\mathrm{d}s + \frac{\alpha t}{1-\alpha\eta}\int_0^\eta (\eta-s)\,\mathrm{d}s \\
&\quad + \frac{t}{1-\alpha\eta}\int_0^1 (1-s)\,\mathrm{d}s\biggr)\cdot mc \\
&= \frac{2-\alpha\eta+\alpha\eta^2}{2(1-\alpha\eta)}\cdot mc \\
&= c.
\end{aligned}$$

Hence, $T : \overline{P}_c \to \overline{P}_c$. In the same way, if $x \in \overline{P}_c$, then assumption (D1) yields $f(t,x(t)) < ma$, $0 \leqslant t \leqslant 1$. As in the argument above, we can obtain that $T : \overline{P}_a \to P_a$. Therefore condition (C2) of Theorem 3.48 is satisfied.

To check condition (C1) of Theorem 3.48, we choose $x(t) = b/\gamma$, $0 \leqslant t \leqslant 1$. It is easy to see that $x(t) = b/\gamma \in P(\psi, b, b/\gamma)$ and $\psi(x) = \psi(b/\gamma) > b$, and so $\{x \in P(\psi, b, b/\gamma)\colon\ \psi(x) > b\} \neq \emptyset$. Hence, if $x \in P(\psi, b, b/\gamma)$, then $b \leqslant x(t) \leqslant b/\gamma$, $\eta \leqslant t \leqslant 1$. From assumption (D2), we have $f(t,x(t)) \geqslant b/\delta$, $\eta \leqslant t \leqslant 1$, and by the definition of ψ and the cone P, we have to distinguish two cases, (i) $\psi(Tx) = Tx(\eta)$ and (ii) $\psi(Tx) = Tx(1)$.

In case (i) we have

$$\begin{aligned}
\psi(Tx) &= Tx(\eta) \\
&= -\int_0^\eta (\eta-s) f\bigl(s,x(s)\bigr)\,\mathrm{d}s - \frac{\alpha\eta}{1-\alpha\eta}\int_0^\eta (\eta-s) f\bigl(s,x(s)\bigr)\,\mathrm{d}s \\
&\quad + \frac{\eta}{1-\alpha\eta}\int_0^1 (1-s) f\bigl(s,x(s)\bigr)\,\mathrm{d}s \\
&\leqslant -\frac{1}{1-\alpha\eta}\int_0^\eta (\eta-s) f\bigl(s,x(s)\bigr)\,\mathrm{d}s + \frac{\eta}{1-\alpha\eta}\int_0^1 (1-s) f\bigl(s,x(s)\bigr)\,\mathrm{d}s \\
&= -\frac{\eta}{1-\alpha\eta}\int_0^\eta f\bigl(s,x(s)\bigr)\,\mathrm{d}s + \frac{1}{1-\alpha\eta}\int_0^\eta s f\bigl(s,x(s)\bigr)\,\mathrm{d}s
\end{aligned}$$

$$
\begin{aligned}
&\quad + \frac{\eta}{1-\alpha\eta}\int_0^1 f\big(s,x(s)\big)\,\mathrm{d}s - \frac{\eta}{1-\alpha\eta}\int_0^1 sf\big(s,x(s)\big)\,\mathrm{d}s \\
&= \frac{\eta}{1-\alpha\eta}\int_\eta^1 f\big(s,x(s)\big)\,\mathrm{d}s + \frac{1}{1-\alpha\eta}\int_0^\eta sf\big(s,x(s)\big)\,\mathrm{d}s \\
&\quad - \frac{\eta}{1-\alpha\eta}\int_0^1 sf\big(s,x(s)\big)\,\mathrm{d}s \\
&> \frac{\eta}{1-\alpha\eta}\int_\eta^1 f\big(s,x(s)\big)\,\mathrm{d}s - \frac{\eta}{1-\alpha\eta}\int_\eta^1 sf\big(s,x(s)\big)\,\mathrm{d}s \\
&\geqslant \frac{\eta}{1-\alpha\eta}\int_\eta^1 (1-s)\,\mathrm{d}s\cdot\frac{b}{\delta} \\
&= \frac{\eta(1-\eta)^2}{2(1-\alpha\eta)}\cdot\frac{b}{\delta} \\
&\geqslant b.
\end{aligned}
$$

In case (ii), we have

$$
\begin{aligned}
\psi(Tx) &= Tx(1) \\
&= -\int_0^1 (1-s)f\big(s,x(s)\big)\,\mathrm{d}s - \frac{\alpha}{1-\alpha\eta}\int_0^\eta (\eta-s)f\big(s,x(s)\big)\,\mathrm{d}s \\
&\quad + \frac{1}{1-\alpha\eta}\int_0^1 (1-s)f\big(s,x(s)\big)\,\mathrm{d}s \\
&= \frac{\alpha\eta}{1-\alpha\eta}\int_0^1 (1-s)f\big(s,x(s)\big)\,\mathrm{d}s - \frac{\alpha}{1-\alpha\eta}\int_0^\eta (\eta-s)f\big(s,x(s)\big)\,\mathrm{d}s \\
&= \frac{\alpha\eta}{1-\alpha\eta}\int_0^1 f\big(s,x(s)\big)\,\mathrm{d}s - \frac{\alpha\eta}{1-\alpha\eta}\int_0^1 sf\big(s,x(s)\big)\,\mathrm{d}s \\
&\quad - \frac{\alpha\eta}{1-\alpha\eta}\int_0^\eta f\big(s,x(s)\big)\,\mathrm{d}s + \frac{\alpha}{1-\alpha\eta}\int_0^\eta sf\big(s,x(s)\big)\,\mathrm{d}s \\
&= \frac{\alpha\eta}{1-\alpha\eta}\int_\eta^1 f\big(s,x(s)\big)\,\mathrm{d}s - \frac{\alpha\eta}{1-\alpha\eta}\int_0^1 sf\big(s,x(s)\big)\,\mathrm{d}s \\
&\quad + \frac{\alpha}{1-\alpha\eta}\int_0^\eta sf\big(s,x(s)\big)\,\mathrm{d}s \\
&> \frac{\alpha\eta}{1-\alpha\eta}\int_\eta^1 f\big(s,x(s)\big)\,\mathrm{d}s - \frac{\alpha\eta}{1-\alpha\eta}\int_\eta^1 sf\big(s,x(s)\big)\,\mathrm{d}s \\
&= \frac{\alpha\eta}{1-\alpha\eta}\int_\eta^1 (1-s)f\big(s,x(s)\big)\,\mathrm{d}s
\end{aligned}
$$

$$\geqslant \frac{\alpha\eta(1-\eta)^2}{2(1-\alpha\eta)} \cdot \frac{b}{\delta}$$
$$\geqslant \delta \cdot \frac{b}{\delta} = b,$$

i.e.

$$\psi(Tx) > b, \quad \forall x \in P(\psi, b, b/\gamma).$$

This shows that condition (C1) of Theorem 3.48 is satisfied. We finally show that (C3) of Theorem 3.48 also holds. Suppose that $x \in P(\psi, b, c)$ with $\|Tx\| > b/\gamma$. Then we have

$$\psi(Tx) = \min_{\eta \leqslant t \leqslant 1} Tx(t) \geqslant \gamma \cdot \|Tx\| > \gamma \cdot b/\gamma = b.$$

So, condition (C3) of Theorem 3.48 is satisfied. Therefore an application of Theorem 3.48 completes the proof. □

Theorem 3.49 was taken from [42]. For the BVP (3.91)–(3.92) Ma in [76] studied multiplicity results at resonance, i.e. when $\alpha\eta = 1$, by developing the methods of lower and upper solutions when the lower and upper solutions are well ordered as well as opposite ordered, by the connectivity properties of the solution set of parameterized families of compact vector fields.

Let us discuss some extensions of the above results.

Consider the following m-point BVP

$$x'' + a(t)f(x) = 0, \quad t \in (0,1), \tag{3.93}$$

$$x(0) = 0, \qquad x(1) = \sum_{i=1}^{m-2} \alpha_i x(\xi_i) \tag{3.94}$$

where $\alpha_i \geqslant 0$ for $i = 1, 2, \ldots, m-3$ and $\alpha_{m-2} > 0$, $0 < \xi_1 < \xi_2 < \cdots < \xi_{m-2} < 1$, $\sum_{i=1}^{m-2} \alpha_i \xi_i < 1$. By using the Krasnosel'skii's fixed point theorem in cones Ma in [72] proved the existence of positive solution of the BVP (3.93)–(3.94) under the assumptions that $a \in C([0,1],[0,\infty))$, and there exists $x_0 \in [\xi_{m-2}, 1]$ such that $a(x_0) > 0$ and $\sum_{i=1}^{m-2} \alpha_i \xi_i < 1$, either in superlinear or sublinear case. The steps of the proof are parallel to that of the proof of Theorem 3.38.

A natural generalization of the boundary condition (3.94) is

$$x(0) = 0, \qquad \int_a^b h(t)x(t)\,\mathrm{d}t = x(1), \tag{3.95}$$

where $[a,b] \subset (0,1)$, $h \in C([a,b],[0,\infty))$, $\int_a^b t h(t)\,\mathrm{d}t \neq 1$ and $b\int_a^b h(t)\,\mathrm{d}t < 1$. The existence of positive solutions for the BVP (3.80), (3.95) is studied by Ma [73] when f is either superlinear or sublinear.

Another result for the following m-point BVP

$$x'' + a(t)f(x) = 0, \quad t \in (0,1), \tag{3.96}$$

$$x'(0) = \sum_{i=1}^{m-2} \beta_i x'(\xi_i), \qquad x(1) = \sum_{i=1}^{m-2} \alpha_i x(\xi_i) \tag{3.97}$$

where $\alpha_i, \beta_i \geqslant 0$ and $\sum_{i=1}^{m-2} \alpha_i < 1$, $\sum_{i=1}^{m-2} \beta_i < 1$, was given by Ma and Castaneda in [71] also by using the Krasnosel'skii's fixed point theorem in cones and either in superlinear or sublinear case. These results were generalized and improved by Liu [58] by applying topological degree methods.

The result for the BVP (3.80), (3.88) was generalized by Guo et al. in [23], where they studied the following BVP (3.80), (3.98) where (3.98) stands for the boundary condition

$$x(0) = 0, \qquad x(1) - \sum_{i=1}^{m-2} \alpha_i x(\xi_i) = b, \tag{3.98}$$

where $b, \alpha_i > 0$ $(i = 1, 2, \dots, m-2)$. In this problem $a(t)$ is allowed to be singular at $t = 0, 1$.

The m-point BVP

$$x'' + f(t,x) = 0, \quad t \in (0,1), \tag{3.99}$$

$$x(0) = 0, \qquad x(1) = \sum_{i=1}^{m-2} \alpha_i x(\xi_i) \tag{3.100}$$

where $\alpha_i > 0$ for $i = 1, 2, \dots, m-2$, $0 < \xi_1 < \xi_2 < \cdots < \xi_{m-2} < 1$, $\sum_{i=1}^{m-2} \alpha_i \xi_i < 1$ and $f : [0,1] \times [0,\infty) \to [0,\infty)$ a continuous function, was studied by Liu et al. in [64] by using the Legget–Williams fixed point theorem and Green's functions.

Existence and multiplicity results for positive solutions for the m-point BVP

$$\begin{aligned} &\big(p(t)x'\big)' - q(t)x + f(t,x) = 0, \quad 0 < t < 1, \\ &ax(0) - bp(0)x'(0) = \sum_{i=1}^{m-2} \alpha_i x(\xi_i), \\ &cx(1) - dp(1)x'(1) = \sum_{i=1}^{m-2} \beta_i x(\xi_i), \end{aligned}$$

where $p, q \in C([0,1], (0,\infty))$, $a, b, c, d \in [0,\infty)$ are given by Ma in [77]. See also [75] for results for superlinear semipositone m-point BVPs.

Three-point BVP of higher-order ordinary differential equations was studied by Liu and Ge in [65] where they consider BVP consisting of the equation

$$x^{(n)} + \lambda a(t) f\bigl(x(t)\bigr) = 0, \quad t \in (0,1)$$

with one of the following boundary value conditions:

$$\begin{aligned} &x(0) = \alpha x(\eta), \qquad x(1) = \beta x(\eta),\\ &x^{(i)}(0) = 0, \quad i = 1,2,\dots,n-2, \end{aligned}$$

and

$$\begin{aligned} &x^{(n-2)}(0) = \alpha x^{(n-2)}(\eta), \qquad x^{(n-2)}(1) = \beta x^{(n-2)}(\eta),\\ &x^{(i)}(0) = 0, \quad i = 1,2,\dots,n-3, \end{aligned}$$

where $\eta \in (0,1)$, $\alpha \geqslant 0$, $\beta \geqslant 0$, and $a:(0,1) \to \mathbb{R}$ may change sign, $f(0) > 0$, and $\lambda > 0$ is a parameter.

For other recent results on positive solutions for nonlocal BVP the interested reader is referred to [13,18,46,48,51,64,67,68] and the references cited therein.

3.10. *Positive solutions of nonlocal boundary value problems with dependence on the first-order derivative*

All the results in the previous section were proved under the assumption that the first derivative x' is not involved explicitly in the nonlinear term. In this section we are concerned with the existence of positive solutions for the second-order three-point BVP

$$x''(t) + f\bigl(t, x(t), x'(t)\bigr), \quad 0 < t < 1, \tag{3.101}$$

$$x(0) = 0, \qquad x(1) = \alpha x(\eta), \tag{3.102}$$

where $f:[0,1] \times [0,\infty) \times \mathbb{R} \to [0,\infty)$ is continuous, $\alpha > 0$, $0 < \eta < 1$ and $1 - \alpha\eta > 0$.

To show the existence of positive solutions to BVP (3.101)–(3.102), we use an extension of Krasnosel'skii's fixed point theorem in cones, proved in [19]. To state this fixed point theorem some notations are necessary.

Let X be a Banach space and $K \subset X$ a cone. Suppose $\alpha, \beta : X \to \mathbb{R}^+$ are two convex functionals satisfying

$$\alpha(\lambda x) = |\lambda| \alpha(x), \quad \beta(\lambda x) = |\lambda| \beta(x), \quad \lambda \in \mathbb{R},$$

and

$$\begin{aligned} &\|x\| \leqslant M \max\bigl\{\alpha(x), \beta(x)\bigr\} && \text{for } x \in X \quad \text{and}\\ &\alpha(x) \leqslant \alpha(y) && \text{for } x, y \in K,\ x \leqslant y, \end{aligned}$$

where $M > 0$ is a constant.

THEOREM 3.50. *Let $r_2 > r_1 > 0$, $L > 0$ be constants and*

$$\Omega_i = \{x \in X\colon\ \alpha(x) < r_i,\ \beta(x) < L\}, \quad i = 1, 2,$$

two bounded open sets in X. Set

$$D_i = \{x \in X\colon\ \alpha(x) = r_i\}.$$

Assume $T : K \to K$ is a completely continuous operator satisfying

(a) $\alpha(Tu) < r_1$, $u \in D_1 \cap K$; $\alpha(Tu) > r_2$, $u \in D_2 \cap K$;
(b) $\beta(Tu) < L$, $u \in K$;
(c) *there is a $p \in (\Omega \cap K) \setminus \{0\}$ such that $\alpha(p) \neq 0$ and $\alpha(x + \lambda p) \geqslant \alpha(x)$ for all $x \in K$ and $\lambda \geqslant 0$.*

Then T has at least one fixed point in $(\Omega_2 \setminus \overline{\Omega}_1) \cap K$.

From Lemmas 3.34 and 3.37 we know that the unique solution of the BVP

$$x'' + y(t) = 0, \quad 0 < t < 1, \qquad x(0) = 0, \qquad x(1) = \alpha x(\eta)$$

is given by

$$\begin{aligned} x(t) = &-\int_0^t (t-s)y(s)\,\mathrm{d}s - \frac{\alpha t}{1-\alpha\eta}\int_0^\eta (\eta - s)y(s)\,\mathrm{d}s \\ &+ \frac{t}{1-\alpha\eta}\int_0^1 (1-s)y(s)\,\mathrm{d}s \end{aligned}$$

and satisfies

$$\min_{t\in[\eta,1]} x(t) \geqslant \gamma\|x\|,$$

where $\gamma = \min\{\alpha\eta, \frac{\alpha(1-\eta)}{1-\alpha\eta}, \eta\}$.

Moreover it is easy to see that, if $1 - \alpha\eta \neq 0$, the Green function for the BVP

$$-x'' = 0, \quad 0 < t < 1, \qquad x(0) = 0, \qquad x(1) = \alpha x(\eta)$$

is given by

$$G(t,s)=\begin{cases}\dfrac{s[(1-t)-\alpha(\eta-t)]}{1-\alpha\eta}, & s\leqslant t,\ s\leqslant\eta,\\ \dfrac{s(1-t)+\alpha\eta(t-s)}{1-\alpha\eta}, & \eta\leqslant s\leqslant t,\\ \dfrac{t[(1-s)-\alpha(\eta-s)]}{1-\alpha\eta}, & t\leqslant s\leqslant\eta,\\ \dfrac{t(1-s)}{1-\alpha\eta}, & t\leqslant s,\ s\geqslant\eta.\end{cases}$$

Let $X=C^1([0,1],\mathbb{R})$ with $\|x\|=\max_{0\leqslant t\leqslant 1}[x^2(t)+(x'(t))^2]^{1/2}$, and $K=\{x\in X\colon\ x(t)\geqslant 0,\ \ x$ is concave on $[0,1]\}$. Define functionals $\alpha(x)=\max_{0\leqslant t\leqslant 1}|x(t)|$ and $\beta(x)=\max_{0\leqslant t\leqslant 1}|x'(t)|$ for each $x\in X$. Then $\|x\|\leqslant\sqrt{2}\max\{\alpha(x),\beta(x)\}$ and

$$\alpha(\lambda x)=|\lambda|\alpha(x),\quad \beta(\lambda x)=|\lambda|\beta(x),\quad x\in X,\ \lambda\in\mathbb{R},$$
$$\alpha(x)\leqslant\alpha(y),\quad \text{for } x,y\in K,\ x\leqslant y.$$

We set

$$M=\max_{0\leqslant t\leqslant 1}\int_0^1 G(t,s)\,\mathrm{d}s,\qquad m=\max_{0\leqslant t\leqslant 1}\int_\eta^1 G(t,s)\,\mathrm{d}s,$$
$$Q=\frac{3-\alpha\eta+\alpha\eta^2}{2(1-\alpha\eta)}.$$

THEOREM 3.51. *Let* $f:[0,1]\times[0,\infty)\times\mathbb{R}\to[0,\infty)$ *be a continuous function,* $\alpha>0$, $0<\eta<1$ *and* $1-\alpha\eta>0$. *Suppose that there are* $L>b>\gamma b>c>0$ *such that* $f(t,u,v)$ *satisfies the growth conditions*:

(1) $f(t,u,v)<c/M$ *for* $(t,u,v)\in[0,1]\times[0,c]\times[-L,L]$;
(2) $f(t,u,v)\geqslant b/m$ *for* $(t,u,v)\in[0,1]\times[\gamma b,b]\times[-L,L]$;
(3) $f(t,u,v)<L/Q$ *for* $(t,u,v)\in[0,1]\times[0,b]\times[-L,L]$.

Then the BVP (3.101)–(3.102) *has at least one positive solution* $y(t)$ *satisfying*

$$c<\alpha(x)<b,\qquad \left|y'(t)\right|<L.$$

PROOF. Take

$$\Omega_1=\left\{x\in X\colon\ \left|x(t)\right|<c,\ \left|x'(t)\right|<L\right\},$$
$$\Omega_2=\left\{x\in X\colon\ \left|x(t)\right|<b,\ \left|x'(t)\right|<L\right\}$$

two bounded open sets in X, and

$$D_1=\left\{x\in X\colon\ \alpha(x)=c\right\},\qquad D_2=\left\{x\in X\colon\ \alpha(x)=b\right\}.$$

Let

$$f^*(t,u,v)=\begin{cases} f(t,u,v), & (t,u,v)\in[0,1]\times[0,b]\times(-\infty,\infty),\\ f(t,b,v), & (t,u,v)\in[0,1]\times(b,\infty)\times(-\infty,\infty),\end{cases}$$

and

$$f_1(t,u,v)=\begin{cases} f^*(t,u,v), & (t,u,v)\in[0,1]\times[0,\infty)\times[-L,L],\\ f^*(t,u,-L), & (t,u,v)\in[0,1]\times[0,\infty)\times(-\infty,-L],\\ f^*(t,u,L), & (t,u,v)\in[0,1]\times[0,\infty)\times[L,\infty).\end{cases}$$

Then $f_1\in C([0,1]\times[0,\infty)\times\mathbb{R},\mathbb{R}^+)$. Define

$$(Tx)(t)=\int_0^1 G(t,s)f_1\big(s,x(s),x'(s)\big)\,\mathrm{d}s.$$

Obviously, $T:K\to K$ is completely continuous, and there is a $p\in(\Omega_2\cap K)\setminus\{0\}$ such that $\alpha(x+\lambda p)\geqslant\alpha(x)$ for all $x\in K$ and $\lambda\geqslant 0$. For $x\in D_1\cap K$, $\alpha(x)=c$. From (1), we get

$$\begin{aligned}\alpha(Tx)&=\max_{t\in[0,1]}\left|\int_0^1 G(t,s)f_1\big(s,x(s),x'(s)\big)\,\mathrm{d}s\right|\\ &<\max_{t\in[0,1]}\int_0^1 G(t,s)\frac{c}{M}\,\mathrm{d}s=\frac{c}{M}\max_{t\in[0,1]}\int_0^1 G(t,s)\,\mathrm{d}s=c.\end{aligned}$$

Whereas for $x\in D_2\cap K$, $\alpha(x)=b$. We have $x(t)\geqslant\gamma\alpha(x)=\gamma b$ for $t\in[\eta,1]$. So, from (2), we get

$$\begin{aligned}\alpha(Tx)&=\max_{t\in[0,1]}\left|\int_0^1 G(t,s)f_1\big(s,x(s),x'(s)\big)\,\mathrm{d}s\right|\\ &>\max_{t\in[0,1]}\left|\int_\eta^1 G(t,s)f_1\big(s,x(s),x'(s)\big)\,\mathrm{d}s\right|\\ &>\max_{t\in[0,1]}\int_\eta^1 G(t,s)\frac{b}{m}\,\mathrm{d}s=\frac{b}{m}\max_{t\in[0,1]}\int_\eta^1 G(t,s)\,\mathrm{d}s=b.\end{aligned}$$

For $x\in K$, from (3), we get

$$\begin{aligned}\beta(Tx)=\max_{t\in[0,1]}\bigg|&-\int_0^t f_1\big(s,x(s),x'(s)\big)\,\mathrm{d}s\\ &+\frac{1}{1-\alpha\eta}\int_0^1(1-s)f_1\big(s,x(s),x'(s)\big)\,\mathrm{d}s\\ &-\frac{\alpha}{1-\alpha\eta}\int_0^\eta(\eta-s)f_1\big(s,x(s),x'(s)\big)\,\mathrm{d}s\bigg|\end{aligned}$$

$$< \left[1 + \frac{1}{1-\alpha\eta}\int_0^1 (1-s)\,\mathrm{d}s + \frac{\alpha}{1-\alpha\eta}\int_0^\eta (\eta - s)\,\mathrm{d}s\right]\frac{L}{Q}$$
$$= \frac{3-\alpha\eta+\alpha\eta^2}{2(1-\alpha\eta)}\frac{L}{Q} = L.$$

Theorem 3.50 implies there is $y \in (\Omega_2 \setminus \overline{\Omega}_1) \cap K$ such that $y = Ty$. So, y is a positive solution for BVP (3.101)–(3.102) satisfying

$$c < \alpha(x) < b, \qquad \left|y'(t)\right| < L.$$

Thus, the proof of the theorem is complete. □

Theorem 3.51 was proved in [19], where one more result was proved in the case when $0 < \alpha \leqslant 1$ and $\eta \in (0,1)$, under the assumptions (1), (2) and the following one

(4) $f(t,u,v) < L^2/(2b)$ for $(t,u,v) \in [0,1] \times [0,b] \times [-L,L]$.

Consider now a three-point BVP

$$\big(p(t)x'(t)\big)' = f\big(t, x(t), x'(t)\big), \quad t \in [0,1], \tag{3.103}$$

$$x'(0) = 0, \qquad x(1) = x(\eta) \tag{3.104}$$

where $f : [0,1] \times \mathbb{R} \times \mathbb{R} \to \mathbb{R}$ is continuous, $p : [0,1] \to \mathbb{R}$ is a positive continuous differentiable function, $\min_{t\in[0,1]} p(t) := p_1 > 0$ and $\eta \in (0,1)$. For this problem the linear operator $Lx(t) = (p(t)x'(t))'$ is not invertible, so the three-point BVP (3.103)–(3.104) is a resonance problem. By using a theorem of a fixed point index for A-proper semilinear operators Bai and Fang [6] proved the following theorem.

THEOREM 3.52. *Suppose*

(1) $f : [0,1] \times \mathbb{R} \times \mathbb{R} \to \mathbb{R}$ *is continuous and there exist constants* $a > 0$, $b > 0$, *and* $0 < c < p_1^2/(2\|p\|_\infty)$ *such that*

$$\left|f(t,x,y)\right| \leqslant a + b|x| + c|y|, \quad \forall t \in [0,1],\ x, y \in \mathbb{R}.$$

(2) *There exists* $M > 0$ *such that*

$$f(t,x,0) > 0, \quad \forall t \in [0,1],\ x > M.$$

(3) $f(t,x,y) \geqslant 0$, $\forall t \in [0,1]$, $y \in \mathbb{R}$ *and there exist constants* $0 < \sigma < b$ *and* $\varepsilon > 0$ *such that*

$$f(t,x,y) \geqslant \sigma x, \quad \forall t \in [0,1],\ 0 \leqslant x \leqslant \varepsilon,\ y \in \mathbb{R}.$$

Then the BVP (3.103)–(3.104) *has at least one positive solution.*

A more general nonlocal BVP was studied by Palamides [87]. He consider the following BVP

$$x''(t) = f\bigl(t, x(t), x'(t)\bigr), \quad t \in (0,1),$$
$$\alpha x(0) - \beta x'(0) = 0, \qquad x(1) = \sum_{i=0}^{m-2} \alpha_i x(\xi_i)$$

with $\alpha \geqslant 0$, $\beta > 0$. Existence of positive solution is given, under superlinear and/or sublinear growth rate in f. A different method is employed based on analysis of the corresponding vector field on the (x, x')-face plane and Kneser's property of the solutions funnel.

Finally positive solutions for $2n$th order nonlocal BVP was studied by Guo et al. in [22] and [20] where they consider BVPs consisting of the equation

$$x^{(2n)}(t) = f\bigl(t, x(t), x''(t), \dots, x^{2(n-1)}(t)\bigr), \quad 0 \leqslant t \leqslant 1,$$

and one of the following boundary conditions:

$$x^{(2i)}(0) = 0, \quad x^{(2i)}(1) = \sum_{j=1}^{m-2} k_{ij} x^{(2i)}(\xi_j), \quad 0 \leqslant i \leqslant n-1,$$

and

$$x^{(2i)}(0) - \beta_i x^{(2i+1)}(0) = 0, \quad x^{(2i)}(1) = \sum_{j=1}^{m-2} k_{ij} x^{(2i)}(\xi_j), \quad 0 \leqslant i \leqslant n-1.$$

They use the Legget–Williams fixed point theorem and a fixed point theorem in double cones respectively.

For other recent results we refer to [49,50,52,53].

3.11. *Positive solutions of nonlocal problems for p-Laplacian*

The purpose of this section is to establish the existence of positive solutions to the following three-point boundary value problem for p-Laplacian

$$\bigl(g(u')\bigr)' + a(t)f(u) = 0, \quad \text{for } 0 < t < 1, \tag{3.105}$$
$$u(0) = 0, \quad \text{and} \quad u(\nu) = u(1), \tag{3.106}$$

where $g(v) = |v|^{p-2}v$, with $p > 1$, and $\nu \in (0,1)$.

We will prove the existence of at least three positive pseudo-symmetric solutions of the BVP (3.105)–(3.106) where we now define what we mean by a pseudo-symmetric function.

DEFINITION 3.53. For $\nu \in (0, 1)$ a function $u \in C[0, 1]$ is said to be pseudo-symmetric if u is symmetric over the interval $[\nu, 1]$. That is, for $t \in [\nu, 1]$ we have $u(t) = u(1 - (t - \nu))$.

In this setting we are able to verify that for all x in our cone $\sigma_u = \frac{1+\nu}{2}$.

In our approach we will use a new multiple fixed point theorem, now called the five functionals fixed point theorem, obtained by Avery [2], which generalized the Leggett–Williams fixed point theorem [55] in terms of functionals rather than norms. We state first the five functional fixed point theorem.

Let γ, β, θ be nonnegative, continuous, convex functionals on P and α, ψ be nonnegative, continuous, concave functionals on P. Then, for nonnegative real numbers h, a, b, d and c, we define the convex sets,

$$\begin{aligned}
P(\gamma, c) &= \{x \in P\colon\ \gamma(x) < c\},\\
P(\gamma, \alpha, a, c) &= \{x \in P\colon\ a \leqslant \alpha(x),\ \gamma(x) \leqslant c\},\\
Q(\gamma, \beta, d, c) &= \{x \in P\colon\ \beta(x) \leqslant d,\ \gamma(x) \leqslant c\},\\
P(\gamma, \theta, \alpha, a, b, c) &= \{x \in P\colon\ a \leqslant \alpha(x),\ \theta(x) \leqslant b,\ \gamma(x) \leqslant c\},
\end{aligned}$$

and

$$Q(\gamma, \beta, \psi, h, d, c) = \{x \in P\colon\ h \leqslant \psi(x),\ \beta(x) \leqslant d,\ \gamma(x) \leqslant c\}.$$

THEOREM 3.54. *Let P be a cone in a real Banach space E. Suppose there exist positive numbers c and M, nonnegative, continuous, concave functionals α and ψ on P, and nonnegative, continuous, convex functionals γ, β, and θ on P, with*

$$\alpha(x) \leqslant \beta(x) \quad \textit{and} \quad \|x\| \leqslant M\gamma(x)$$

for all $x \in \overline{P(\gamma, c)}$. Suppose

$$A : \overline{P(\gamma, c)} \to \overline{P(\gamma, c)}$$

is completely continuous and there exist nonnegative numbers h, a, k, b, with $0 < a < b$ such that:

(i) *$\{x \in P(\gamma, \theta, \alpha, b, k, c)\colon\ \alpha(x) > b\} \neq \emptyset$ and $\alpha(Ax) > b$ for $x \in P(\gamma, \theta, \alpha, b, k, c)$;*
(ii) *$\{x \in Q(\gamma, \beta, \psi, h, a, c)\colon\ \beta(x) < a\} \neq \emptyset$ and $\beta(Ax) < a$ for $x \in Q(\gamma, \beta, \psi, h, a, c)$;*
(iii) *$\alpha(Ax) > b$ for $x \in P(\gamma, \alpha, b, c)$ with $\theta(Ax) > k$;*
(iv) *$\beta(Ax) < a$ for $x \in Q(\gamma, \beta, a, c)$ with $\psi(Ax) < h$.*

Then A has at least three fixed points $x_1, x_2, x_3 \in \overline{P(\gamma, c)}$ such that,

$$\beta(x_1) < a, \qquad b < \alpha(x_2),$$

and

$$a < \beta(x_3) \quad \textit{with}\ \alpha(x_3) < b.$$

Assume $f:[0,\infty)\to[0,\infty)$ is continuous, and let $a:[0,1]\to[0,\infty)$ be continuous. Let $\nu\in(0,1)$, and let $E=C[0,1]$ be the Banach space with the sup-norm, $\|u\|=\sup\{|u(x)|:\ 0\leqslant x\leqslant 1\}$, and define the cone $P\subset E$ by

$$P=\bigl\{u\in E:\ u(0)=0,\ u \text{ is concave, and } u \text{ is symmetric on } [\nu,1]\bigr\}.$$

Hereafter, suppose $\nu\in(0,1)$, with $\int_0^\nu a(r)\,\mathrm{d}r>0$, and we will choose a $\delta\in(0,\nu)$, such that $\int_\delta^\nu a(t)\,\mathrm{d}t>0$, and the constants M^* and m^*, defined by

$$M^*=\int_0^\nu G\biggl(\int_s^\sigma a(r)\,\mathrm{d}r\biggr)\,\mathrm{d}s,$$

and

$$m^*=\int_0^\delta G\biggl(\int_s^\sigma a(r)\,\mathrm{d}r\biggr)\,\mathrm{d}s,$$

satisfy the inequality $\nu<\frac{m^*}{M^*}$. Trivially, we have $\delta<\frac{m^*}{M^*}$. We let

$$m=\int_0^\delta G\biggl(\int_\delta^\nu a(r)\,\mathrm{d}r\biggr)\,\mathrm{d}s=\delta G\biggl(\int_\delta^\nu a(r)\,\mathrm{d}r\biggr)$$

and

$$M=\int_0^\sigma G\biggl(\int_s^\sigma a(r)\,\mathrm{d}r\biggr)\,\mathrm{d}s,$$

as well as,

$$h_1=\int_\delta^\nu G\biggl(\int_s^\sigma a(r)\,\mathrm{d}r\biggr)\,\mathrm{d}s,$$

$$h_2=\int_0^\delta G\biggl(\int_s^\delta a(r)\,\mathrm{d}r\biggr)\,\mathrm{d}s,$$

and

$$h_3=\int_0^\delta G\biggl(\int_\delta^\sigma a(r)\,\mathrm{d}r\biggr)\,\mathrm{d}s.$$

Define the nonnegative, continuous, concave functionals α, ψ, and the nonnegative, continuous, convex functionals β, θ, γ on the cone P by:

$$\gamma(x)=\theta(x):=\max_{t\in[0,1]}x(t)=x(\sigma),$$

$$\beta(x):=\max_{t\in[\delta,\nu]}x(t)=x(\nu),$$

$$\alpha(x)=\psi(x):=\min_{t\in[\delta,\nu]}x(t)=x(\nu).$$

In our main result, we will make use of the following lemma. The lemma is easily proved using the concavity and the pseudo-symmetry of all $u\in P$.

LEMMA 3.55. *Let $x\in P$. Then*
(D1) $u(\delta)\geqslant\delta u(1)=\delta u(\nu)$, *and*
(D2) $\sigma u(\nu)\geqslant\nu u(\sigma)=\nu\|u\|$.

We are now ready to apply the five functionals fixed point theorem to an operator A to give sufficient conditions for the existence of at least three positive pseudo-symmetric solutions to (3.105)–(3.106).

THEOREM 3.56. *Assume that $\nu\in(0,1)$, $a:[0,1]\to[0,\infty)$ is a pseudo-symmetric continuous function, $\delta\in(0,\nu)$ such that*

$$\int_\delta^\nu a(t)\,\mathrm{d}t>0\quad \textit{with } \nu<\frac{m^*}{M^*},$$

and $f:[0,\infty)\to[0,\infty)$ is continuous. Let $0<a<b<c$, with $ch_2<aM$, and suppose that f satisfies the following conditions:
(i) $f(x)>g(\frac{b}{m})$ *for all* $b\leqslant x\leqslant\frac{b}{\delta}$,
(ii) $f(x)<g(\frac{Ma-ch_2}{M(h_1+h_3)})$ *for all* $a\delta\leqslant x\leqslant\frac{a\sigma}{\nu}$, *and*
(iii) $f(x)\leqslant g(\frac{c}{M})$ *for all* $0\leqslant x\leqslant c$.
Then the three-point boundary value problem (3.105)–(3.106) *has at least three positive pseudo-symmetric solutions u_1,u_2,u_3 such that*

$$\max_{t\in[\delta,\nu]}u_1(t)<a<\max_{t\in[\delta,\nu]}u_2(t)\quad\textit{and}\quad\min_{t\in[\delta,\nu]}u_2(t)<b<\min_{t\in[\delta,\nu]}u_3(t).$$

PROOF. Define the completely continuous operator A on P by

$$Au(t)=w(t)=\begin{cases}\displaystyle\int_0^t G\left(\int_s^\sigma a(r)f\big(u(r)\big)\,\mathrm{d}r\right)\mathrm{d}s, & 0\leqslant t\leqslant\sigma,\\ \displaystyle w(\nu)+\int_t^1 G\left(\int_\sigma^s a(r)f\big(u(r)\big)\,\mathrm{d}r\right)\mathrm{d}s, & \sigma\leqslant t\leqslant 1,\end{cases}$$

where

$$\sigma=\frac{\nu+1}{2}.$$

We first note that for $u\in P$ we have $Au(t)\geqslant 0$, $Au(0)=0$, and applying the Fundamental Theorem of Calculus we have that Au is concave. Furthermore, for $t\in[\nu,1]$

$$Au(t)=Au\big(1-(t-\nu)\big).$$

Consequently, $Au \in P$, that is, $A : P \to P$. Moreover, since

$$\big(g\big((Au)'\big)\big)'(t) = -a(t)f\big(u(t)\big) \leqslant 0 \quad \text{for all } 0 < t < 1,$$

we have that all fixed points of A are solutions of (3.105)–(3.106). Thus we set out to verify that the operator A satisfies the five functionals fixed point theorem which will prove the existence of three fixed points of A which satisfy the conclusion of the theorem.

If $u \in \overline{P(\gamma, c)}$, then $\gamma(u) = \max_{t\in[0,1]} u(t) \leqslant c$. Thus

$$\begin{aligned}
\gamma(Au) &= Au(\sigma) \\
&= \int_0^\sigma G\bigg(\int_s^\sigma a(r)f\big(u(r)\big)\,\mathrm{d}r\bigg)\,\mathrm{d}s \\
&\leqslant \int_0^\sigma G\bigg(\int_s^\sigma a(r)g\bigg(\frac{c}{M}\bigg)\,\mathrm{d}r\bigg)\,\mathrm{d}s \\
&= \bigg(\frac{c}{M}\bigg)\int_0^\sigma G\bigg(\int_s^\sigma a(r)\,\mathrm{d}r\bigg)\,\mathrm{d}s \\
&= c.
\end{aligned}$$

Hence,

$$A : \overline{P(\gamma, c)} \to \overline{P(\gamma, c)}.$$

Next, let $N = \frac{m^* + \delta M^*}{2}$. Thus $m^* > N > \delta M^*$, and if we define

$$u_P(t) = \begin{cases} \bigg(\dfrac{b}{N}\bigg)\displaystyle\int_0^t G\bigg(\int_s^\sigma a(r)\,\mathrm{d}r\bigg)\,\mathrm{d}s, & 0 \leqslant t \leqslant \sigma, \\ u_P(\nu) + \bigg(\dfrac{b}{N}\bigg)\displaystyle\int_t^1 G\bigg(\int_\sigma^s a(r)\,\mathrm{d}r\bigg)\,\mathrm{d}s, & \sigma \leqslant t \leqslant 1, \end{cases}$$

and

$$u_Q(t) = \begin{cases} \bigg(\dfrac{a\delta}{N}\bigg)\displaystyle\int_0^t G\bigg(\int_s^\sigma a(r)\,\mathrm{d}r\bigg)\,\mathrm{d}s, & 0 \leqslant t \leqslant \sigma, \\ u_Q(\nu) + \bigg(\dfrac{a\delta}{N}\bigg)\displaystyle\int_t^1 G\bigg(\int_\sigma^s a(r)\,\mathrm{d}r\bigg)\,\mathrm{d}s, & \sigma \leqslant t \leqslant 1, \end{cases}$$

then, clearly $u_P, u_Q \in P$. Furthermore,

$$\alpha(u_P) = u_P(\delta) = \bigg(\frac{b}{N}\bigg)\int_0^\delta G\bigg(\int_s^\sigma a(r)\,\mathrm{d}r\bigg)\,\mathrm{d}s = \frac{bm^*}{N} > b,$$

and

$$\theta(u_P) = u_P(\nu) = \bigg(\frac{b}{N}\bigg)\int_0^\nu G\bigg(\int_s^\sigma a(r)\,\mathrm{d}r\bigg)\,\mathrm{d}s = \frac{bM^*}{N} < \frac{b}{\delta},$$

as well as,

$$\psi(u_Q) = u_Q(\delta) = \left(\frac{a\delta}{N}\right)\int_0^\delta G\left(\int_s^\sigma a(r)\,\mathrm{d}r\right)\mathrm{d}s = \frac{a\delta m^*}{N} > a\delta,$$

and

$$\beta(u_Q) = u_Q(\nu) = \left(\frac{a\delta}{N}\right)\int_0^\nu G\left(\int_s^\sigma a(r)\,\mathrm{d}r\right)\mathrm{d}s = \frac{aM^*\delta}{N} < a.$$

Therefore,

$$u_P \in \left\{u \in P\left(\gamma, \theta, \alpha, b, \frac{b}{\delta}, c\right) \colon \alpha(u) > b\right\},$$

and

$$u_Q \in \left\{u \in Q(\gamma, \beta, \psi, a\delta, a, c) \colon \beta(u) < a\right\},$$

hence, these sets are nonempty.

If $u \in P(\gamma, \theta, \alpha, b, \frac{b}{\delta}, c)$, then $b \leqslant u(t) \leqslant \frac{b}{\delta}$, for all $t \in [\delta, \nu]$, and thus by condition (i) of this theorem,

$$\begin{aligned}
\alpha(Au) &= Au(\delta) \\
&= \int_0^\delta G\left(\int_s^\sigma a(r) f\big(u(r)\big)\,\mathrm{d}r\right)\mathrm{d}s \\
&\geqslant \int_0^\delta G\left(\int_\delta^\nu a(r) f\big(u(r)\big)\,\mathrm{d}r\right)\mathrm{d}s \\
&> \int_0^\delta G\left(\int_\delta^\nu a(r) g\left(\frac{b}{m}\right)\mathrm{d}r\right)\mathrm{d}s \\
&= \left(\frac{b}{m}\right)\int_0^\delta G\left(\int_\delta^\nu a(r)\,\mathrm{d}r\right)\mathrm{d}s \\
&= b.
\end{aligned}$$

Hence, condition (i) of the five functionals fixed point theorem is satisfied.

If $u \in P(\gamma, \alpha, b, c)$ with $\theta(Au) > \frac{b}{\delta}$, then by Lemma 3.55(D1), we have

$$\alpha(Au) = Au(\delta) \geqslant \delta Au(1) = \delta Au(\nu) = \delta\theta(Au) > b.$$

Thus, condition (iii) of the five functionals fixed point theorem is satisfied.

If $u \in Q(\gamma, \beta, \psi, a\delta, a, c)$, then $a\delta \leqslant u(t) \leqslant a$, for all $t \in [\delta, \nu]$, and thus by Lemma 3.55(D2), $a\delta \leqslant u(t) \leqslant \frac{a\sigma}{\nu}$, for all $t \in [\delta, \sigma]$. Thus by condition (ii) of this theorem,

$$\begin{aligned}
\beta(Au) &= Au(\nu) \\
&= \int_0^\nu G\left(\int_s^\sigma a(r) f\big(u(r)\big)\,\mathrm{d}r\right)\mathrm{d}s \\
&= \int_0^\delta G\left(\int_s^\sigma a(r) f\big(u(r)\big)\,\mathrm{d}r\right)\mathrm{d}s + \int_\delta^\nu G\left(\int_s^\sigma a(r) f\big(u(r)\big)\,\mathrm{d}r\right)\mathrm{d}s \\
&\leqslant \int_0^\delta G\left(\int_s^\delta a(r) f\big(u(r)\big)\,\mathrm{d}r\right)\mathrm{d}s + \int_0^\delta G\left(\int_\delta^\sigma a(r) f\big(u(r)\big)\,\mathrm{d}r\right)\mathrm{d}s \\
&\quad + \int_\delta^\nu G\left(\int_s^\sigma a(r) f\big(u(r)\big)\,\mathrm{d}r\right)\mathrm{d}s \\
&< \left(\frac{c}{M}\right)\int_0^\delta G\left(\int_s^\delta a(r)\,\mathrm{d}r\right)\mathrm{d}s \\
&\quad + \left(\frac{Ma - ch_2}{M(h_1 + h_3)}\right)\int_0^\delta G\left(\int_\delta^\sigma a(r)\,\mathrm{d}r\right)\mathrm{d}s \\
&\quad + \left(\frac{Ma - ch_2}{M(h_1 + h_3)}\right)\int_\delta^\nu G\left(\int_s^\sigma a(r)\,\mathrm{d}r\right)\mathrm{d}s \\
&= \frac{ch_2}{M} + \frac{(Ma - ch_2)h_3}{M(h_1 + h_3)} + \frac{(Ma - ch_2)h_1}{M(h_1 + h_3)} \\
&= a.
\end{aligned}$$

Hence, condition (ii) of the five functionals fixed point theorem is satisfied.

If $u \in Q(\gamma, \beta, a, c)$, with $\psi(Au) < a\delta$, then by Lemma 3.55, we have

$$\beta(Au) = Au(\nu) \leqslant \frac{Au(\delta)}{\delta} = \frac{\psi(Au)}{\delta} < a.$$

Consequently, condition (iv) of the five functionals fixed point theorem is also satisfied. Therefore, the hypotheses of the five functionals fixed point theorem 3.54 are satisfied, and there exist at least three positive pseudo-symmetric solutions $u_1, u_2, u_3 \in \overline{P(\gamma, c)}$ for the three-point boundary value problem (3.105)–(3.106) such that,

$$\beta(u_1) < a < \beta(u_2) \quad \text{and} \quad \alpha(u_2) < b < \alpha(u_3). \qquad \square$$

Theorem 3.56 was taken from [3]. Existence of positive solutions for the BVP (3.105)–(3.106) was proved also in [91] and [41], relying on Krasnosel'skii's and Legget–Williams fixed point theorems respectively. BVP with p-Laplacian and more general boundary conditions was studied in [66], where the boundary conditions $u(0) - B_0(u'(\eta)) = 0, u'(1) = 0$

and $u'(0)=0, u(1)+B_1(u'(\eta))=0$ are used and in [4,5] where the m-point boundary conditions $u(0)=0, u(1)=\sum_{i=1}^{m-2} a_i u(\xi_i)$ and $u'(0)=\sum_{i=1}^{m-2} b_i u'(\xi_i)$, $u(1)=\sum_{i=1}^{m-2} a_i u(\xi_i)$ are used. Finally multi-point BVP for p-Laplacian at resonance was proved by Ni and Ge in [85] and Garcia-Huidobro et al. in [17].

Author Index

Roman numbers refer to pages on which the author (or his/her work) is mentioned. Italic numbers refer to reference pages. Numbers between brackets are the reference numbers. No distinction is made between first and co-author(s).

HANDBOOK OF DIFFERENTIAL EQUATIONS
Ordinary Differential Equations, volume 3
Edited by A. Cañada, P. Drábek and A. Fonda
© 2006 Elsevier B.V. All rights reserved

1. Introduction

The classical courses of ordinary differential equations (ODEs) start either with the Peano existence theorem (see, e.g., [54]) or with the Picard–Lindelöf existence and uniqueness theorem (see, e.g., [71]), both related to the Cauchy (initial value) problems

$$\begin{cases} \dot{x} = f(t, x), \\ x(0) = x_0, \end{cases} \tag{1.1}$$

where $f \in C([0, \tau] \times \mathbb{R}^n, \mathbb{R}^n)$, and

$$\bigl|f(t, x) - f(t, y)\bigr| \leqslant L|x - y|, \quad \text{for all } t \in [0, \tau] \text{ and } x, y \in \mathbb{R}^n, \tag{1.2}$$

in the latter case.

In fact, if f satisfies the Lipschitz condition (1.2), then "*uniqueness implies existence*" even for boundary value problems with linear conditions that are "close" to $x(0) = x_0$, as observed in [53]. Moreover, *uniqueness implies* in general (i.e. not necessarily, under (1.2)) *continuous dependence of solutions on initial values* (see, e.g., [54, Theorem 4.1 in Chapter 4.2]), and subsequently the *Poincaré translation operator* $T_\tau : \mathbb{R}^n \to \mathbb{R}^n$, at the time $\tau > 0$, along the trajectories of $\dot{x} = f(t, x)$, defined as follows:

$$T_\tau(x_0) := \bigl\{x(\tau) \mid x(.) \text{ is a solution of } (1.1)\bigr\}, \tag{1.3}$$

is a homeomorphism (cf. [54, Theorem 4.4 in Chapter 4.2]).

Hence, besides the existence, uniqueness is also a very important problem. W. Orlicz [92] showed in 1932 that the set of continuous functions $f : U \to \mathbb{R}^n$, where U is an open subset relative to $[0, \tau] \times \mathbb{R}^n$, for which problem (1.1) with $(0, x_0) \in U$ is not uniquely solvable, is meager, i.e. a set of the first Baire category. In other words, the generic continuous Cauchy problems (1.1) are solvable in a unique way. Therefore, no wonder that the first example of nonuniqueness was constructed only in 1925 by M.A. Lavrentev (cf. [71] and, for more information, see, e.g., [1]). The same is certainly also true for Carathéodory ODEs, because the notion of a *classical* (C^1-) *solution* can be just replaced by the *Carathéodory solution*, i.e. absolutely continuous functions satisfying (1.1), almost everywhere (a.e.). The change is related to the application of the Lebesgue integral, instead of the Riemann integral.

On the other hand, H. Kneser [80] proved in 1923 that the sets of solutions to continuous Cauchy problems (1.1) are, at every time, continua (i.e. compact and connected). This result was later improved by M. Hukuhara [75] who proved that the solution set itself is a continuum in $C([0, \tau], \mathbb{R}^n)$. N. Aronszajn [41] specified in 1942 that these continua are R_δ-sets (see Definition 2.3 below), and as a subsequence, multivalued operators T_τ in (1.3) become *admissible* in the sense of L. Górniewicz (see Definition 2.5 below).

Obviously if, for $f(t, x) \equiv f(t + \tau, x)$, operator T_τ admits a *fixed point*, say $\hat{x} \in \mathbb{R}^n$, i.e. $\hat{x} \in T_\tau(\hat{x})$, then $\hat{x}$ determines a τ-periodic solution of $\dot{x} = f(t, x)$, and vice versa. This is one of stimulations why to study the fixed point theory for multivalued mappings in order to obtain periodic solutions of nonuniquely solvable ODEs. Since the regularity of (multivalued) Poincaré's operator T_τ is the same (see Theorem 4.17 below) for differential inclusions $\dot{x} \in F(t,x)$, where F is an upper Carathéodory mapping with nonempty, convex and compact values (see Definition 2.10 below), it is reasonable to study directly such differential inclusions with this respect. Moreover, initial value problems for differential inclusions are, unlike ODEs, typically nonuniquely solvable (cf. [42]) by which Poincaré's operators are multivalued.

In this context, an interesting phenomenon occurs with respect to the Sharkovskii cycle coexistence theorem [95]. This theorem is based on a new ordering of the positive integers, namely

$$\begin{aligned} &3 \rhd 5 \rhd 7 \rhd \cdots \rhd 2\cdot 3 \rhd 2\cdot 5 \rhd 2\cdot 7 \rhd \cdots \rhd 2^2\cdot 3 \rhd 2^2\cdot 5 \rhd 2^2\cdot 7 \rhd \cdots \\ &\quad \rhd 2^n\cdot 3 \rhd 2^n\cdot 5 \rhd 2^n\cdot 7 \rhd \cdots \rhd 2^{n+1}\cdot 3 \rhd 2^{n+1}\cdot 5 \rhd 2^{n+1}\cdot 7 \rhd \cdots \\ &\quad \rhd 2^{n+1} \rhd 2^n \rhd \cdots \rhd 2^2 \rhd 2 \rhd 1, \end{aligned}$$

saying that *if a continuous function* $g : \mathbb{R} \to \mathbb{R}$ *has a point of period* m *with* $m \rhd k$ (in the above Sharkovskii ordering), *then it has also a point of period* k.

By a period, we mean the least period, i.e. a point $a \in \mathbb{R}$ is a *periodic point of period* m if $g^m(a) = a$ and $g^j(a) \neq a$, for $0 < j < m$.

Now, consider the scalar ODE

$$\dot{x} = f(t,x), \quad f(t,x) \equiv f(t+\tau, x), \tag{1.4}$$

where $f : [0,\tau] \times \mathbb{R} \to \mathbb{R}$ is a continuous function.

Since

$$T_\tau^m = \underbrace{T_\tau \circ \cdots \circ T_\tau}_{m \text{ times}} = T_{m\tau}$$

holds for the Poincaré translation operator T_τ along the trajectories of Eq. (1.4), defined in (1.3), there is (in the case of uniqueness) an apparent one-to-one correspondence between m-periodic points of T_τ and (subharmonic) $m\tau$-periodic solutions of (1.4). Nevertheless, the analogy of classical Sharkovskii's theorem does not hold for subharmonics of (1.4). In fact, we only obtain an empty statement, because every bounded solution of (1.4) is, under the uniqueness assumption, either τ-periodic or asymptotically τ-periodic (see, e.g., [94, pp. 120–122]).

This handicap is due to the assumed uniqueness condition. On the other hand, in the lack of uniqueness, the multivalued operator T_τ in (1.3) is admissible (see Theorem 4.17 below) which in $\mathbb{R}$ means (cf. Definition 2.5 below) that T_τ is upper semicontinuous (cf. Definition 2.4 below) and the sets of values consist either of single points or of compact intervals. In a series of our papers [16,29,36], we developed a version of the Sharkovskii cycle coexistence theorem which applies to (1.4) as follows:

THEOREM 1.1. *If Eq.* (1.4) *has an* $m\tau$*-periodic solution, then it also admits a* $k\tau$*-periodic solution, for every* $k \lhd m$, *with at most two exceptions, where* $k \lhd m$ *means that* k *is less*

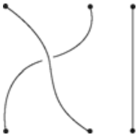

Fig. 1. Braid σ.

than m in the above Sharkovskii ordering of positive integers. In particular, if $m \neq 2^k$, *for all* $k \in \mathbb{N}$, *then infinitely many* (*subharmonic*) *periodic solutions of* (1.4) *coexist.*

REMARK 1.1. As pointed out, Theorem 1.1 holds only in the lack of uniqueness; otherwise, it is empty. On the other hand, the right-hand side of the given (multivalued) ODE can be a (multivalued upper) Carathéodory mapping with nonempty, convex and compact values (see Definition 2.10 below).

REMARK 1.2. Although, e.g., a 3τ-periodic solution of (1.4) implies, for every $k \in \mathbb{N}$, with a possible exception for $k = 2$ or $k = 4, 6$, the existence of a $k\tau$-periodic solution of (1.4), it is very difficult to prove that such a solution exists. Observe that a 3τ-periodic solution of (1.4) implies the existence of at least two more 3τ-periodic solutions of (1.4).

The Sharkovskii phenomenon is essentially one-dimensional. On the other hand, it follows from T. Matsuoka's results in [87–89] that three (harmonic) τ-periodic solutions of the planar (i.e. in $\mathbb{R}^2$) system (1.4) imply "generically" the coexistence of infinitely many (subharmonic) $k\tau$-periodic solutions of (1.4), $k \in \mathbb{N}$. "Genericity" is this time understood in terms of the Artin braid group theory, i.e. with the exception of certain simplest braids, representing the three given harmonics.

The following theorem was presented in [8], on the basis of T. Matsuoka's results in papers [87–89].

THEOREM 1.2. *Assume that a uniqueness condition is satisfied for planar system* (1.4). *Let three* (*harmonic*) τ*-periodic solutions of* (1.4) *exist whose graphs are not conjugated to the braid* σ^m *in* B_3/Z, *for any integer* $m \in \mathbb{N}$, *where* σ *is shown in Fig.* 1, B_3/Z *denotes the factor group of the Artin braid group* B_3 *and* Z *is its center* (*for definitions*, *see*, *e.g.*, [22, Chapter III.9]). *Then there exist infinitely many* (*subharmonic*) $k\tau$*-periodic solutions of* (1.4), $k \in \mathbb{N}$.

REMARK 1.3. In the absence of uniqueness, there occur serious obstructions, but Theorem 1.2 still seems to hold in many situations; for more details see [8].

REMARK 1.4. The application of the Nielsen theory considered in Section 3.2 below might determine the desired three harmonic solutions of (1.4). More precisely, it is more realistic to detect two harmonics by means of the related Nielsen number (see again Section 3.2 below), and the third one by means of the related fixed point index (see Section 3.3 below).

For $n > 2$, statements like Theorem 1.1 or Theorem 1.2 appear only rarely. Nevertheless, if $f = (f_1, f_2, \dots, f_n)$ has a special triangular structure, i.e.

$$f_i(x) = f_i(x_1, \dots, x_n) = f_i(x_1, \dots, x_i), \quad i = 1, \dots, n, \tag{1.5}$$

then Theorem 1.1 can be extended to hold in $\mathbb{R}^n$ (see [35]).

THEOREM 1.3. *Under assumption* (1.5), *the conclusion of Theorem* 1.1 *remains valid in* $\mathbb{R}^n$.

REMARK 1.5. Similarly to Theorem 1.1, Theorem 1.3 holds only in the lack of uniqueness. Without the special triangular structure (1.5), there is practically no chance to obtain an analogy to Theorem 1.1, for $n \geqslant 2$.

There is also another motivation for the investigation of *multivalued ODEs*, i.e. differential inclusions, because of the strict connection with

(i) optimal control problems for ODEs,
(ii) Filippov solutions of discontinuous ODEs,
(iii) implicit ODEs, etc.

ad (i): Consider a *control problem* for

$$\dot{x} = f(t, x, u), \quad u \in U, \tag{1.6}$$

where $f : [0, \tau] \times \mathbb{R}^n \times \mathbb{R}^n \to \mathbb{R}^n$ and $u \in U$ are control parameters such that $u(t) \in \mathbb{R}^n$, for all $t \in [0, \tau]$. In order to solve a control problem for (1.6), we can define a multivalued map $F(t, x) := \{f(t, x, u)\}_{u \in U}$. The solutions of (1.6) are those of

$$\dot{x} \in F(t, x), \tag{1.7}$$

and the same is true for a given control problem. For more details, see, e.g., [27,79].

ad (ii): If function f is discontinuous in x, then Carathéodory theory cannot be applied for solving, e.g., (1.1). Making, however, the *Filippov regularization* of f, namely

$$F(t, x) := \bigcap_{\delta > 0} \bigcap_{\substack{r \subset [0,\tau] \times \mathbb{R}^n \\ \mu(r) = 0}} \overline{\operatorname{conv}}\, f\big(O_\delta\big((t, x) \setminus r\big)\big), \tag{1.8}$$

where $\mu(r)$ denotes the Lebesgue measure of the set $r \subset \mathbb{R}^n$ and

$$O_\delta(y) := \big\{z \in [0, \tau] \times \mathbb{R}^n \mid |y - z| < \delta\big\},$$

multivalued F is well known (see [60]) to be again upper Carathéodory with nonempty, convex and compact values (cf. Definition 2.10 below), provided only f is measurable and satisfies $|f(t, x)| \leqslant \alpha + \beta|x|$, for all $(t, x) \in [0, \tau] \times \mathbb{R}^n$, with some nonnegative constants α, β. Thus, by a *Filippov solution* of $\dot{x} = f(t, x)$, it is so understood a Carathéodory solution of (1.7), where F is defined in (1.8). As an example from physics, dry friction problems (see, e.g., [84,91]) can be solved in this way.

ad (iii): Let us consider the *implicit differential equation*

$$\dot{x} = f(t, x, \dot{x}), \tag{1.9}$$

where $f : [0, \tau] \times \mathbb{R}^n \times \mathbb{R}^n \to \mathbb{R}^n$ is a compact (continuous) map and the solutions are understood in the sense of Carathéodory. We can associate with (1.9) the following two differential inclusions:

$$\dot{x} \in F_1(t, x) \tag{1.10}$$

and

$$\dot{x} \in F_2(t, x), \tag{1.11}$$

where $F_1(t, x) := \operatorname{Fix}(f(t, x, \cdot))$, i.e. the (nonempty, see [22, p. 560]) fixed point set of $f(t, x, \cdot)$ w.r.t. the last variable, and $F_2 \subset F_1$ is a (multivalued) lower semicontinuous (see Definition 2.4 below) selection of F_1. The sufficient condition for the existence of such a selection F_2 reads (see, e.g., [22, Chapter III.11, pp. 558–559]):

$$\dim \operatorname{Fix}\bigl(f(t, x, \cdot)\bigr) = 0, \quad \text{for all } (t, x) \in [0, \tau] \times \mathbb{R}^n, \tag{1.12}$$

where dim denotes the topological (covering) dimension.

Denoting by $S(f)$, $S(F_1)$, $S(F_2)$ the sets of all solutions of initial value problems to (1.9), (1.10), (1.11), respectively, one can prove (see [22, p. 560]) that, under (1.12), $S(f) = S(F_1) \subset S(F_2) \neq \emptyset$. For more details, see [19] (cf. [22, Chapter III.11]).

Although there are several monographs devoted to multivalued ODEs (see, e.g., [22,42, 45,58,61,74,79,91,96,97]), topological principles were presented mainly for single-valued ODEs (besides [22,45,58] and [61] for differential inclusions, see, e.g., [62,64,65,82,83, 90]). Hence our main object will be topological principles for (multivalued) ODEs; whence the title. We will consider without special distinguishing differential equations as well as inclusions; both in Euclidean and Banach spaces. All solutions of problems under our consideration (even in Banach spaces) will be understood at least in the sense of Carathéodory. Thus, in view of the indicated relationship with problems (i)–(iii), many obtained results can be also employed for solving optimal control problems, problems for systems with variable structure, implicit boundary value problems, etc.

The reader exclusively interested in single-valued ODEs can simply read “continuous”, instead of “upper semicontinuous” or “lower semicontinuous”, and replace the inclusion symbol $\in$ by the equality $=$, in the given differential inclusions. If, in the single-valued case, the situation simplifies dramatically or if the obtained results can be significantly improved, then the appropriate remarks are still supplied.

We wished to prepare an as much as possible self-contained text. Nevertheless, the reader should be at least familiar with the elements of nonlinear analysis, in particular of fixed point theory, in order to understand the degree arguments, or so. Otherwise, we recommend the monographs [69] (in the single-valued case) and [22] (in the multivalued case).

Furthermore, one is also expected to know several classical results and notions from the standard courses of ODEs, functional analysis and the theory of integration like the Gronwall inequality, the Arzelà–Ascoli lemma, the Mazur Theorem, the Bochner integral, etc.

We will study mainly existence and multiplicity of bounded, periodic and anti-periodic solutions of (multivalued) ODEs. Since our approach consists in the application of the fixed point principles, these solutions will be either determined by, (e.g., τ-periodic solutions $x(t)$ by the initial values $x(0)$ via (1.3)) or directly identified (e.g., solutions of initial value problems (1.1)) with fixed points of the associated (Cauchy, Hammerstein, etc.) operators.

Although the usage of the relative degree (i.e. the fixed point index) arguments is rather traditional in this framework, it might not be so when the maps, representing, e.g., problems on noncompact intervals, operate in nonnormable Fréchet spaces. This is due to the unpleasant locally convex topology possessing bounded subsets with an empty interior. We had therefore to develop with my colleagues our own fixed point index theory. The application of the Nielsen theory, for obtaining multiplicity criteria, is very delicate and quite rare, and the related problem is named after Jean Leray who posed it in 1950, at the first International Congress of Mathematics held after World War II in Cambridge, Mass. We had also to develop a new multivalued Nielsen theory suitable for applications in this field. Before presenting general methods for solvability of boundary value problems in Section 4, we therefore make a sketch of the applied fixed point principles in Section 3. Hence besides Section 4, the main results are contained in Section 5 (Existence results) and Section 6 (Multiplicity results). The reference sources to our results and their comparison with those of other authors are finally commented in Section 7 (Remarks and comments).

2. Preliminaries

2.1. *Elements of ANR-spaces*

In the entire text, all topological spaces will be metric and, in particular, all topological vector spaces will be at least Fréchet. Let us recall that by a *Fréchet space*, we understand a complete (metrizable) locally convex space. Its topology can be generated by a countable family of seminorms. If it is normable, then it becomes *Banach*.

DEFINITION 2.1. A (metrizable) space X is an *absolute neighbourhood retract* (ANR) if, for each (metrizable) Y and every closed $A \subset Y$, each continuous mapping $f : A \to X$ is extendable over some neighbourhood of A.

PROPOSITION 2.1.

(i) *If X is an ANR, then any open subset of X is an ANR and any neighbourhood retract of X is an ANR.*

(ii) *X is an ANR if and only if it is a neighbourhood retract of every* (*metrizable*) *space in which it is embedded as a closed subset.*

(iii) *X is an ANR if and only if it is a neighbourhood retract of some normed linear space, i.e. if and only if it is a retract of some open subset of a normed space.*

(iv) *If X is a retract of an open subset of a convex set in a Fréchet space, then it is an ANR.*
(v) *If X_1, X_2 are closed ANRs such that $X_1 \cap X_2$ is an ANR, then $X_1 \cup X_2$ is an ANR.*
(vi) *Any finite union of closed convex sets in a Fréchet space is an ANR.*
(vii) *If each $x \in X$ admits a neighbourhood that is an ANR, then X is an ANR.*

DEFINITION 2.2. A (metrizable) space X is an *absolute retract* (AR) if, for each (metrizable) Y and every closed $A \subset Y$, each continuous mapping $f : A \to X$ is extendable over Y.

PROPOSITION 2.2.
(i) *X is an AR if and only if it is a contractible (i.e. homotopically equivalent to a one point space) ANR.*
(ii) *X is an AR if and only if it is a retract of every (metrizable) space in which it is embedded as a closed subset.*
(iii) *If X is an AR and A is a retract of X, then A is an AR.*
(iv) *If X is homeomorphic to Y and X is an AR, then so is Y.*
(v) *X is an AR if and only if it is a retract of some normed space.*
(vi) *If X is a retract of a convex subset of a Fréchet space, then it is an AR.*
(vii) *If X_1, X_2 are closed ARs such that $X_1 \cap X_2$ is an AR, then $X_1 \cup X_2$ is an AR.*

Furthermore, it is well known that every ANR X is *locally contractible* (i.e. for each $x \in X$ and a neighbourhood U of x, there exists a neighbourhood V of x that is contractible in U) and, as follows from Proposition 2.2(i) that every AR X is *contractible* (i.e. if $\mathrm{id}_X : X \to X$ is homotopic to a constant map).

DEFINITION 2.3. X is called an *R_δ-set* if, there exists a decreasing sequence $\{X_n\}$ of compact, contractible sets X_n such that $X = \bigcap\{X_n \mid n = 1, 2, \ldots\}$.

Although contractible spaces need not be ARs, X is an R_δ-set if and only if it is an intersection of a decreasing sequence of compacts ARs. Moreover, every R_δ-set is *acyclic* w.r.t. any continuous theory of homology (e.g., the Čech homology), i.e. homologically equivalent to a one point space, and so it is in particular nonempty, compact and connected.

The following hierarchies hold for metric spaces:

$$\begin{array}{ccccc} & & \text{contractible} & \subset & \text{acyclic} \\ & & \cup & & \\ \text{convex} & \subset & \text{AR} & \subset & \text{ANR,} \end{array}$$

compact + convex $\subset$ compact AR $\subset$ compact + contractible $\subset R_\delta \subset$ compact + acyclic, and all the above inclusions are proper.

For more details, see [47] (cf. also [22,67,69]).

2.2. *Elements of multivalued maps*

In what follows, by a multivalued map $\varphi : X \multimap Y$, i.e. $\varphi : X \to 2^Y \backslash \{0\}$, we mean the one with at least nonempty, closed values.

DEFINITION 2.4. A map $\varphi : X \multimap Y$ is said to be *upper semicontinuous* (u.s.c.) if, for every open $U \subset Y$, the set $\{x \in X \mid \varphi(x) \subset U\}$ is open in X. It is said to be *lower semicontinuous* (l.s.c.) if, for every open $U \subset Y$, the set $\{x \in X \mid \varphi(x) \cap U \neq \emptyset\}$ is open in X. If it is both u.s.c. and l.s.c., then it is called *continuous*.

Obviously, in the single-valued case, if $f : X \to Y$ is u.s.c. or l.s.c., then it is continuous. Moreover, the compact-valued map $\varphi : X \multimap Y$ is continuous if and only if it is *Hausdorff-continuous*, i.e. continuous w.r.t. the metric d in X and the Hausdorff-metric d_H in $\{B \subset Y \mid B$ is nonempty and bounded$\}$, where $d_H(A, B) := \inf\{\varepsilon > 0 \mid A \subset O_\varepsilon(B)$ and $B \subset O_\varepsilon(A)\}$ and $O_\varepsilon(B) := \{x \in X \mid \exists y \in B\colon\ d(x, y) < \varepsilon\}$. Every u.s.c. map $\varphi : X \multimap Y$ has a closed graph Γ_φ, but not vice versa. Nevertheless, if the graph Γ_φ of a compact map $\varphi : X \multimap Y$ is closed, then φ is u.s.c.

The important role will be played by the following class of admissible maps in the sense of L. Górniewicz.

DEFINITION 2.5. Assume that we have a diagram $X \overset{p}{\Longleftarrow} \Gamma \xrightarrow{q} Y$ (Γ is a metric space), where $p : \Gamma \Rightarrow X$ is a continuous *Vietoris map*, namely

(i) p is onto, i.e. $p(\Gamma) = X$,
(ii) p is proper, i.e. $p^{-1}(K)$ is compact, for every compact $K \subset X$,
(iii) $p^{-1}(x)$ is acyclic, for every $x \in X$, where acyclicity is understood in the sense of the Čech homology functor with compact carriers and coefficients in the field $\mathbb{Q}$ of rationals,

and $q : \Gamma \to Y$ is a continuous map. The map $\varphi : X \multimap Y$ is called *admissible* if it is induced by $\varphi(x) = q(p^{-1}(x))$, for every $x \in X$. We, therefore, identify the admissible map φ with the pair (p, q) called an *admissible* (*selected*) *pair*.

DEFINITION 2.6. Let $X \overset{p_0}{\Longleftarrow} \Gamma_0 \xrightarrow{q_0} Y$ and $X \overset{p_1}{\Longleftarrow} \Gamma_1 \xrightarrow{p_1} Y$ be two admissible maps, i.e. $\varphi_0 = q_0 \circ p_0^{-1}$ and $\varphi_1 = q_1 \circ p_1^{-1}$. We say that φ_0 is *admissibly homotopic* to φ_1 (written $\varphi_0 \sim \varphi_1$ or $(p_0, q_0) \sim (p_1, q_1)$) if there exists an admissible map $X \times [0, 1] \overset{p}{\Longleftarrow} \Gamma_0 \xrightarrow{q} Y$ such that the following diagram is commutative:

$$\begin{tikzcd}
X \arrow[d, "k_i"'] & \Gamma_i \arrow[l, Leftarrow, "p_i"'] \arrow[r, "q_i"] \arrow[d, "f_i"'] & Y \\
X \times [0,1] & \Gamma \arrow[l, Leftarrow, "p"] \arrow[ur, dashed, "q"'] &
\end{tikzcd}$$

for $k_i(x) = (x, i)$, $i = 0, 1$, and $f_i : \Gamma_i \to \Gamma$ is a homeomorphism onto $p^{-1}(X \times i)$, $i = 0, 1$, i.e. $k_0 p_0 = p f_0$, $q_0 = q f_0$, $k_1 p_1 = p f_1$ and $q_1 = q f_1$.

Thus, admissible maps are always u.s.c. with nonempty, compact and connected values. Moreover, their class is closed w.r.t. finite compositions, i.e. a finite composition of admissible maps is also admissible. In fact, a map is admissible if and only if it is a finite composition of *acyclic maps* with compact values, i.e. u.s.c. maps with acyclic and compact values.

The class of admissible maps so contains u.s.c. maps with convex and compact values, u.s.c. maps with contractible and compact values, R_δ*-maps* (i.e. u.s.c. maps with R_δ-values), acyclic maps with compact values and their compositions.

The class of compact admissible maps $\varphi : X \multimap Y$, i.e. $\overline{\varphi(X)}$ is compact, will be denoted by $\mathbb{K}(X, Y)$, or simply by $\mathbb{K}(X)$, provided φ is a self-map (an endomorphism). If the admissible homotopy in Definition 2.6 is still compact, then we say that $\varphi_0 \in \mathbb{K}(X, Y)$ and $\varphi_1 \in \mathbb{K}(X, Y)$ are *compactly admissibly homotopic*.

Another important class of admissible maps are condensing admissible maps denoted by $\mathbb{C}(X, Y)$. For this, we need to recall the notion of a measure of noncompactness (MNC).

Let E be a Fréchet space endowed with a countable family of seminorms $\|.\|_s$, $s \in S$ (S is the index set), generating the locally convex topology. Denoting by $\mathcal{B} = \mathcal{B}(E)$ the set of nonempty, bounded subsets of E, we can give

DEFINITION 2.7. The family of functions $\alpha = \{\alpha_s\}_{s\in S} : \mathcal{B} \to [0, \infty)^S$, where $\alpha_s(B) := \inf\{\delta > 0 \mid B \in \mathcal{B}$ admits a finite covering by the sets of $\operatorname{diam}_s \leqslant \delta\}$, $s \in S$, for $B \in \mathcal{B}$, is called the *Kuratowski measure of noncompactness* and the family of functions $\gamma = \{\gamma_s\}_{s\in S} : \mathcal{B} \to [0, \infty)^S$, where $\gamma_s(B) := \inf\{\delta > 0 \mid B \in \mathcal{B}$ has a finite ε_s-net$\}$, $s \in S$, for $B \in \mathcal{B}$, is called the *Hausdorff measure of noncompactness*.

These MNC are related as follows:

$$\gamma(B) \leqslant \alpha(B) \leqslant 2\gamma(B), \quad \text{i.e.} \quad \gamma_s(B) \leqslant \alpha_s(B) \leqslant 2\gamma_s(B), \quad \text{for each } s \in S.$$

Moreover, they satisfy the following properties:

PROPOSITION 2.3. *Assume that* $B, B_1, B_2 \in \mathcal{B}$. *Then we have* (*component-wise*):

(μ_1) (regularity) $\mu(B) = 0 \Leftrightarrow \overline{B}$ *is compact*,

(μ_2) (nonsingularity) $\{b\} \in \mathcal{B} \Rightarrow \{b\} \cup B \in \mathcal{B}$ *and* $\mu(\{b\} \cup B) = \mu(B)$,

(μ_3) (monotonicity) $B_1 \subset B_2 \Rightarrow \mu(B_1) \leqslant \mu(B_2)$,

(μ_4) (closed convex hull) $\mu(\overline{\operatorname{conv}} B) = \mu(B)$,

(μ_5) (closure) $\mu(\overline{B}) = \mu(B)$,

(μ_6) (Kuratowski condition) *decreasing sequence of closed sets* $B_n \in \mathcal{B}$ *with*

$$\lim_{n\to\infty} \mu(B_n) = 0 \quad \Longrightarrow \quad \bigcap\{B_n \mid n = 1, 2, \ldots\} \neq \emptyset,$$

(μ_7) (semiadditivity) $\mu(B_1 + B_2) \leqslant \mu(B_1) + \mu(B_2)$,

(μ_8) (union) $\mu(B_1 \cup B_2) = \max\{\mu(B_1), \mu(B_2)\}$,

(μ_9) (intersection) $\mu(B_1 \cap B_2) = \min\{\mu(B_1), \mu(B_2)\}$,

(μ_{10}) (seminorm) $\mu(\lambda B) = |\lambda|\mu(B)$, *for every* $\lambda \in \mathbb{R}$, *and* $\mu(B_1 \cup B_2) \leqslant \mu(B_1) + \mu(B_2)$, *where μ denotes either α or γ.*

DEFINITION 2.8. A bounded mapping $\varphi : E \supset U \multimap E$, i.e. $\varphi(B) \in \mathcal{B}$, for $\mathcal{B} \ni B \subset U$, is said to be *$\mu$-condensing* (shortly, *condensing*) if $\mu(\varphi(B)) < \mu(B)$, whenever $\mathcal{B} \ni B \subset U$ and $\mu(B) > 0$, or equivalently, if $\mu(\varphi(B)) \geqslant \mu(B)$ implies $\mu(B) = 0$, whenever $\mathcal{B} \ni B \subset U$, where $\mu = \{\mu_s\}_{s \in S} : \mathcal{B} \to [0, \infty)^S$ is a family of functions satisfying at least conditions (μ_1)–(μ_5). Analogously, a bounded mapping $\varphi : E \supset U \multimap E$ is said to be a *k-set contraction* w.r.t. $\mu = \{\mu_s\}_{s \in S} : \mathcal{B} \to [0, \infty)^S$ satisfying at least conditions (μ_1)–(μ_5) (shortly, a *k-contraction* or a *set-contraction*) if $\mu(\varphi(B)) \leqslant k\mu(B)$, for some $k \in [0, 1)$, whenever $\mathcal{B} \ni B \subset U$.

Obviously, any set-contraction is condensing and both α-condensing and γ-condensing maps are μ-condensing. Furthermore, compact maps or contractions with compact values (in vector spaces, also their sum) are well known to be (α, γ)-set-contractions, and so (α, γ)-condensing.

Besides semicontinuous maps, measurable and semi-Carathéodory maps will be also of importance. Hence, assume that Y is a separable metric space and $(\Omega, \mathcal{U}, \nu)$ is a *measurable space*, i.e. a set Ω equipped with σ-algebra $\mathcal{U}$ of subsets and a countably additive measure ν on $\mathcal{U}$. A typical example is when Ω is a bounded domain in $\mathbb{R}^n$, equipped with the Lebesgue measure.

DEFINITION 2.9. A map $\varphi : \Omega \multimap Y$ is called *strongly measurable* if there exists a sequence of step multivalued maps $\varphi_n : \Omega \multimap Y$ such that $d_H(\varphi_n(\omega), \varphi(\omega)) \to 0$, for a.a. $\omega \in \Omega$, as $n \to \infty$. In the single-valued case, one can simply replace multivalued step maps by single-valued step maps and $d_H(\varphi_n(\omega), \varphi(\omega))$ by $\|\varphi_n(\omega) - \varphi(\omega)\|$.

A map $\varphi : \Omega \multimap Y$ is called *measurable* if $\{\omega \in \Omega \mid \varphi(\omega) \subset V\} \in \mathcal{U}$, for each open $V \subset Y$.

A map $\varphi : \Omega \multimap Y$ is called *weakly measurable* if $\{\omega \in \Omega \mid \varphi(\omega) \subset V\} \in \mathcal{U}$, for each closed $V \subset Y$.

Obviously, if φ is strongly measurable, then it is measurable and if φ is measurable, then it is also weakly measurable. If φ has compact values, then the notions of measurability and weak measurability coincide. In separable Banach spaces Y, the notions of strong measurability and measurability coincide for multivalued maps with compact values as well as for single-valued maps (see [78, Theorem 1.3.1 on pp. 45–49]). If Y is a not necessarily separable Banach space, then a strongly measurable map $\varphi : \Omega \multimap Y$ with compact values has a single-valued strongly measurable selection (see, e.g., [58, Proposition 3.4(b) on pp. 25–26]). Furthermore, if Y is a separable complete space, then every measurable $\varphi : \Omega \multimap Y$ has, according to the Kuratowski–Ryll-Nardzewski theorem (see, e.g., [22, Theorem 3.49 in Chapter I.3]), a single-valued measurable selection.

Now, let $\Omega = [0, a]$ be equipped with the Lebesgue measure and X, Y be Banach.

DEFINITION 2.10. A map $\varphi : [0, a] \times X \multimap Y$ with nonempty, compact and convex values is called *u-Carathéodory* (resp. *l-Carathéodory*, resp. *Carathéodory*) if it satisfies

(i) $t \multimap \varphi(t, x)$ is strongly measurable, for every $x \in X$,

(ii) $x \multimap \varphi(t, x)$ is u.s.c. (resp. l.s.c., resp. continuous), for almost all $t \in [0, a]$,

(iii) $\|y\|_Y \leqslant r(t)(1+\|x\|_X)$, for every $(t,x) \in [0,a] \times X$, $y \in \varphi(t,x)$, where $r : [0,a] \to [0,\infty)$ is an integrable function.

For $X = \mathbb{R}^m$ and $Y = \mathbb{R}^n$, one can state

PROPOSITION 2.4.

(i) *Carathéodory maps are product-measurable* (*i.e. measurable as the whole* $(t,x) \multimap \varphi(t,x)$), *and*

(ii) *they possess a single-valued Carathéodory selection.*

It need not be so for u-Carathéodory or l-Carathéodory maps. Nevertheless, for u-Carathéodory maps, we have at least (again $X = \mathbb{R}^m$ and $Y = \mathbb{R}^n$).

PROPOSITION 2.5. *u-Carathéodory maps* (*in the sense of Definition* 2.10) *are weakly superpositionally measurable*, *i.e. the composition* $\varphi(t,q(t))$ *admits*, *for every* $q \in C([0,a],\mathbb{R}^m)$, *a single-valued measurable selection. If they are still product-measurable*, *then they are also superpositionally measurable*, *i.e. the composition* $\varphi(t,q(t))$ *is measurable*, *for every* $q \in C([0,a],\mathbb{R}^m)$.

REMARK 2.1. If X, Y are separable Banach spaces and $\varphi : X \multimap Y$ is a Carathéodory mapping, then φ is also superpositionally measurable, i.e. $\varphi(t,q(t))$ is measurable, for every $q \in C([0,a],X)$ (see [78, Theorem 1.3.4 on p. 56]). Under the same assumptions, Proposition 2.4 can be appropriately generalized (see [73, Proposition 7.9 on p. 229 and Proposition 7.23 on pp. 234–235]).

If $\varphi : X \multimap Y$ is only u-Carathéodory and X, Y are (not necessarily separable) Banach spaces, then φ is weakly superpositionally measurable, i.e. $\varphi(t,q(t))$ admits a single-valued measurable selection, for every $q \in C([0,a],X)$ (see, e.g., [58, Proposition 3.5 on pp. 26–27] or [78, Theorem 1.3.5 on pp. 57–58]).

For more details, see [22,40,58,67,73,78].

2.3. *Some further preliminaries*

Assume we have again a diagram (see Definition 2.5)

$$\begin{tikzcd} X & \Gamma \arrow[l, Rightarrow, "p"'] \arrow[r, "q"] & Y \end{tikzcd}$$

where $p : \Gamma \Longrightarrow X$ is a Vietoris map and $q : \Gamma \longrightarrow Y$ is continuous.

Taking $\varphi(x) = q(p^{-1}(x))$, for every $x \in X$, and denoting as

$$\mathrm{Fix}(p,q) = \mathrm{Fix}(\varphi) := \bigl\{x \in X \mid x \in \varphi(x)\bigr\},$$
$$C(p,q) := \bigl\{z \in \Gamma \mid p(z) = q(z)\bigr\}$$

the sets of *fixed points* and *coincidence points* of the admissible pair (p, q), it is clear that $p(C(p, q)) = \mathrm{Fix}(p, q)$, and so

$$\mathrm{Fix}(p, q) \neq \emptyset \quad \Longleftrightarrow \quad C(p, q) \neq \emptyset.$$

The following Aronszajn–Browder–Gupta-type result (see [21, Theorem 3.15]; cf. [22, Theorem 1.4]) is very important in order to say something about the topological structure of $\mathrm{Fix}(\varphi)$.

PROPOSITION 2.6. *Let X be a metric space, E a Fréchet space, $\{U_k\}$ a base of open convex symmetric neighbourhoods of the origin in E, and let $\varphi : X \multimap E$ be a u.s.c proper map with compact values. Assume that there is a convex symmetric subset C of E and a sequence of compact, convex-valued u.s.c. proper maps $\varphi_k : X \multimap E$ such that*

(i) $\varphi_k(x) \subset \varphi(O_{1/k}(x)) + U_k$, *for every $x \in X$, where*

$$O_{1/k}(x) = \left\{y \in X \mid d(x, y) < \tfrac{1}{k}\right\},$$

(ii) *for every $k \geqslant 1$, there is a convex, symmetric set $V_k \subset \overline{U}_k \cap C$ such that V_k is closed in E and $0 \in \varphi(x)$ implies $\varphi_k(x) \cap V_k \neq \emptyset$,*

(iii) *for every $k \geqslant 1$ and every $u \in V_k$, the inclusion $u \in \varphi_k(x)$ has an acyclic set of solutions.*

Then the set $S = \{x \in X \mid \varphi(x) \cap \{0\} \neq \emptyset\}$ is compact and acyclic.

Now, let us assume that E is a Fréchet space, C is a convex subset of E, U is an open subset of C, $\mu : \mathcal{B} \to [0, \infty)^S$ is a measure of noncompactness satisfying at least conditions (μ_1)–(μ_5) in Proposition 2.3 (see Definitions 2.7 and 2.8).

If $\varphi \in \mathbb{C}(U, C)$, then $\mathrm{Fix}(\varphi)$ can be proved relatively compact. We can say more about $\mathrm{Fix}(\varphi)$.

DEFINITION 2.11. Let $(p, q) \in \mathbb{C}(U, C)$. A nonempty, compact, convex set $S \subset C$ is called a *fundamental set* if:

(i) $q(p^{-1}(U \cap S)) \subset S$,

(ii) if $x \in \overline{\mathrm{conv}}(\varphi(x) \cup S)$, then $x \in S$.

For a homotopy $\chi \in \mathbb{C}(U \times [0, 1], C)$, $S \subset C$ is called fundamental if it is fundamental to $\chi(., \lambda)$, for each $\lambda \in [0, 1]$.

PROPOSITION 2.7. *Assume $(p, q) \in \mathbb{C}(U, C)$.*

(i) *If S is a fundamental set for (p, q), then* $\mathrm{Fix}(p, q) \subset S$.

(ii) *Intersection of fundamental sets, for (p, q), is also fundamental, for (p, q).*

(iii) *The family of all fundamental sets for (p, q) is nonempty.*

(iv) *If S is a fundamental set for $\chi \in \mathbb{C}(U \times [0, 1], C)$ and $P \subset S$, then the set $\overline{\mathrm{conv}}(\chi((U \cap S) \times [0, 1]) \cup P)$ is also fundamental.*

For more details, see [22,67], and the references therein.

3. Applied fixed point principles

3.1. *Lefschetz fixed point theorems*

We start with the Lefschetz theory, because it is a base for our further investigation. More precisely, the generalized Lefschetz number can be used for the definition of essential classes in the Nielsen theory as well as the possible normalization property of the fixed point index. We restrict ourselves only to the presentation of necessary facts.

Consider a multivalued map $\varphi : X \multimap X$ and assume that

(i) X is a (metric) ANR-space, e.g., a retract of an open subset of a convex set in a Fréchet space,

(ii) φ is a compact (i.e. $\overline{\varphi(X)}$ is compact) composition of an R_δ-map $p^{-1} : X \multimap \Gamma$ and a continuous (single-valued) map $q : \Gamma \to X$, namely $\varphi = q \circ p^{-1}$, where Γ is a metric space.

Then an integer $\Lambda(\varphi) = \Lambda(p, q)$, called the *generalized Lefschetz number* for $\varphi \in \mathbb{K}(X)$, is well-defined (see, e.g., [12; 22, Chapter I.6; 67]) and $\Lambda(\varphi) \neq 0$ implies that

$$\mathrm{Fix}(\varphi) := \{x \in X \mid x \in \varphi(x)\} \neq \emptyset.$$

Moreover, Λ is a homotopy invariant, namely if φ is compactly homotopic (in the same class of maps) with $\widetilde{\varphi} : X \multimap X$, then $\Lambda(\varphi) = \Lambda(\widetilde{\varphi})$.

In order to define the generalized Lefschetz number, one should be familiar with the elements of algebraic topology, in particular, of homology theory. Therefore, we only briefly sketch this definition without proofs. For more details, we recommend [51,68] (in the single-valued case) and [12,22,67] (in the multivalued case).

At first, we recall some algebraic preliminaries. In what follows, all vector spaces are taken over $\mathbb{Q}$. Let $f : E \to E$ be an endomorphism of a finite-dimensional vector space E. If $v_1, \dots, v_n$ is a basis for E, then we can write

$$f(v_i) = \sum_{j=1}^{n} a_{ij} v_j, \quad \text{for all } i = 1, \dots, n.$$

The matrix $[a_{ij}]$ is called the matrix of f (with respect to the basis $v_1, \dots, v_n$). Let $A = [a_{ij}]$ be an $(n \times n)$-matrix; then the trace of A is defined as $\sum_{i=1}^{n} a_{ii}$. If $f : E \to E$ is an endomorphism of a finite-dimensional vector space E, then the trace of f, written $\mathrm{tr}(f)$, is the trace of the matrix of f with respect to some basis for E. If E is a trivial vector space then, by definition, $\mathrm{tr}(f) = 0$. It is a standard result that the definition of the trace of an endomorphism is independent of the choice of the basis for E.

Hence, let $E = \{E_q\}$ be a graded vector space of a finite type.

If $f = \{f_q\}$ is an endomorphism of degree zero of such a graded vector space, then the (*ordinary*) *Lefschetz number* $\lambda(f)$ of f is defined by

$$\lambda(f) = \sum_q (-1)^q \,\mathrm{tr}(f_q).$$

Let $f : E \to E$ be an endomorphism of an arbitrary vector space E. Denote by $f^n : E \to E$ the nth iterate of f and observe that the kernels

$$\ker f \subset \ker f^2 \subset \cdots \subset \ker f^n \subset \cdots$$

form an increasing sequence of subspaces of E. Let us now put

$$N(f) = \bigcup_n \ker f^n \quad \text{and} \quad \widetilde{E} = E/N(f).$$

Clearly, f maps $N(f)$ into itself and, therefore, induces the endomorphism $\widetilde{f} : \widetilde{E} \to \widetilde{E}$ on the factor space $\widetilde{E} = E/N(f)$.

Let $f : E \to E$ be an endomorphism of a vector space E. Assume that $\dim \widetilde{E} < \infty$. In this case, we define the generalized trace $\mathrm{Tr}(f)$ of f by putting $\mathrm{Tr}(f) = \mathrm{tr}(\widetilde{f})$.

LEMMA 3.1. *Let $f : E \to E$ be an endomorphism. If* $\dim E < \infty$, *then* $\mathrm{Tr}(f) = \mathrm{tr}(f)$.

For the proof, see [22].

Let $f = \{f_q\}$ be an endomorphism of degree zero of a graded vector space $E = \{E_q\}$. We say that f is a *Leray endomorphism* if the graded vector space $\widetilde{E} = \{\widetilde{E}_q\}$ is of finite type. For such an f, we define the (*generalized*) *Lefschetz number* $\Lambda(f)$ of f by putting

$$\Lambda(f) = \sum_q (-1)^q \,\mathrm{Tr}(f_q).$$

It is immediate from Lemma 3.1 that

LEMMA 3.2. *Let $f : E \to E$ be an endomorphism of degree zero, i.e., $f = \{f_q\}$ and $f_q : E_q \to E_q$ is a linear map. If E is a graded vector space of finite type, then* $\Lambda(f) = \lambda(f)$.

Now, the *Lefschetz number* will be defined for admissible compact mappings. For our needs in the sequel, it is enough to consider only the compact compositions of R_δ-maps and continuous single-valued maps as above (by which Lefschetz sets simplify into Lefschetz numbers). Let $\varphi : E \multimap E$ be an admissible compact map and $(p, q) \subset \varphi$ be a selected pair of φ. Then the induced homomorphism $q_* \circ p_*^{-1} : H_*(E) \to H_*(E)$ is an endomorphism of the graded vector space $H_*(E)$ into itself. So, we can define the Lefschetz number $\Lambda(p, q)$ of the pair (p, q) by putting $\Lambda(p, q) = \Lambda(q_* \circ p_*^{-1})$, provided the Lefschetz number $\Lambda(q_* \circ p_*^{-1})$ is well-defined.

It allows us to define the Lefschetz set Λ of φ as follows:

$$\Lambda(\varphi) = \big\{\Lambda(p, q) \mid (p, q) \subset \varphi\big\}.$$

In what follows, we say that the Lefschetz set $\Lambda(\varphi)$ of φ is *well-defined* if, for every $(p, q) \subset \varphi$, the Lefschetz number $\Lambda(p, q)$ of (p, q) is defined.

Moreover, from the homotopy property of Λ, we get:

LEMMA 3.3.

(i) *If* $\varphi, \psi : E \multimap E$ *are compactly homotopic* ($\varphi \sim \psi$), *then*: $\Lambda(\varphi) \cap \Lambda(\psi) \neq \emptyset$.

(ii) *If* $\varphi : E \multimap E$ *is admissible and* E *is acyclic*, *then the Lefschetz set* $\Lambda(\varphi)$ *is well-defined and* $\Lambda(\varphi) = \{1\}$.

It is useful to formulate

THEOREM 3.1 (Coincidence theorem). *Let* U *be an open subset of a finite dimensional normed space* E. *Consider the following diagram*:

$$U \xLeftarrow{p} \Gamma \xrightarrow{q} U$$

in which q *is a compact map. Then the Lefschetz number* $\Lambda(p, q)$ *of the pair* (p, q), *given by the formula*

$$\Lambda(p, q) = \Lambda\big(q_* \circ p_*^{-1}\big),$$

is well-defined, *and* $\Lambda(p, q) \neq 0$ *implies that* $p(y) = q(y)$, *for some* $y \in \Gamma$.

Theorem 3.1 can be reformulated in terms of multivalued mappings as follows.

Let $U \subset E$ be the same as in Theorem 3.1 and let $\varphi : U \multimap U$ be a compact, admissible map, i.e., $\varphi \in \mathbb{K}(U)$. We let $\Lambda(\varphi) = \{\Lambda(p, q) \mid (p, q) \subset \varphi\}$, where $\Lambda(p, q) = \Lambda(q_* \circ p_*^{-1})$. Then we have:

THEOREM 3.2.

(i) *The set* $\Lambda(\varphi)$ *is well-defined*, *i.e. for every* $(p, q) \subset \varphi$, *the generalized Lefschetz number* $\Lambda(p, q)$ *of the pair* (p, q) *is well-defined*, *and*

(ii) $\Lambda(\varphi) \neq \{0\}$ *implies that the set* $\mathrm{Fix}(\varphi) := \{x \in U \mid x \in \varphi(x)\}$ *is nonempty.*

Theorem 3.2 can be generalized, by means of the Schauder-like approximation technique (for more details, see [22]), for compact admissible maps $\varphi \in \mathbb{K}$ on ANR-spaces, e.g., on retracts of open subsets of convex sets in Fréchet spaces, as follows.

THEOREM 3.3 (The Lefschetz fixed point theorem). *Let* X *be an ANR-space*, *e.g.*, *a retract of an open subset* U *of a convex set in a Fréchet space. Assume*, *furthermore*, *that* $\varphi \in \mathbb{K}(X)$. *Then*:

(i) *the Lefschetz set* $\Lambda(\varphi)$ *of* φ *is well-defined*,

(ii) *if* $\Lambda(\varphi) \neq \{0\}$, *then* $\mathrm{Fix}(\varphi) \neq \emptyset$.

REMARK 3.1. If admissible map $\varphi \in \mathbb{K}(X)$ is a composition of an R_δ-map and a continuous single-valued map, then $\Lambda(\varphi)$ is an integer. If, in particular, X is an AR-space, then $\Lambda(\varphi) = 1$.

REMARK 3.2. The definition of a generalized Lefschetz number for condensing maps is far from to be obvious, and so it can not be used as a normalization property for the related fixed points index. Roughly speaking, it requires to assume additionally the existence of a compact attractor or to impose some additional restrictions on the set X like to be a special neighbourhood retract of a Fréchet space (cf. [68]).

3.2. *Nielsen fixed point theorems*

The standard Nielsen theory allows us to obtain the lower estimate of the number of fixed points. More precisely, if $f : X \to X$ is a compact (continuous) map on a (metric) ANR-space X, then a nonnegative integer $N(f)$, called the *Nielsen number* of f, is defined such that

- $N(f) \leqslant \#\mathrm{Fix}(f) := \mathrm{card}\{\hat{x} \in X \mid f(\hat{x}) = \hat{x}\}$,
- $N(f) = N(\widetilde{f})$, for any compact $\widetilde{f} : X \to X$ which is *compactly homotopic* to f, i.e. if there is a compact map $h : X \times [0,1] \to X$ such that $h_0 = f$, $h_1 = \widetilde{f}$, where $h_t(x) := h(x,t)$, for $t \in [0,1]$.

Given a compact $f : X \to X$ on $X \in$ ANR, we say that $x, y \in \mathrm{Fix}(f)$ are *Nielsen related* if there exists a path $u : [0,1] \to X$ such that $u(0) = x$, $u(1) = y$, and u, $f(u)$ are homotopic keeping the endpoints fixed. Since the Nielsen relation is an equivalence, $\mathrm{Fix}(f)$ splits into fixed point classes. Since the classes are open and f is compact, we have a finite number of fixed point classes.

If, for a Nielsen class $\mathcal{N} \subset \mathrm{Fix}(f)$, we have $\mathrm{ind}(\mathcal{N}, f) \neq 0$, i.e. if the associated fixed point index is nontrivial, then $\mathcal{N}$ is called *essential*. The *Nielsen number* $N(f)$ is then defined to be the number of essential Nielsen classes. For more details, see, e.g., [77].

To compute $N(f)$ can be a difficult task. In the multivalued case, the situation is even more delicate, because the above definition can not be directly generalized. Thus, we only indicate this subtle definition again. Nevertheless, in the single-valued case, these definitions are equivalent.

Consider a multivalued map $\varphi : X \multimap X$ and assume that

(i) X is a connected ANR-space, e.g., a connected retract of an open subset of a convex set in a Fréchet space,
(ii) X has a finitely generated abelian fundamental group,
(iii) φ is a compact (i.e. $\overline{\varphi(X)}$ is compact) composition of an R_δ-map $p^{-1} : X \multimap \Gamma$ and a continuous (single-valued) map $q : \Gamma \to X$, namely $\varphi = q \circ p^{-1}$, where Γ is a metric space.

Then a nonnegative integer $N(\varphi) = N(p,q)$,[1] called the *Nielsen number* for $\varphi \in \mathbb{K}$, exists (see [24] and [22, Chapter I.10] or [12]) such that $N(\varphi) \leqslant \#C(\varphi)$, where

$$\#C(\varphi) = \#C(p,q) := \mathrm{card}\big\{z \in \Gamma \mid p(z) = q(z)\big\}$$

and $N(\varphi_0) = N(\varphi_1)$, for compactly homotopic maps $\varphi_0 \sim \varphi_1$.

REMARK 3.3. Condition (ii) is satisfied, provided X is the torus $\mathbb{T}^n$ ($\pi_1(\mathbb{T}^n) = \mathbb{Z}^n$) and it can be avoided if X is compact and $q = \mathrm{id}$ is the identity (cf. [5]).

---

[1] We should write more correctly $N_H(\varphi) = N_H(p,q)$, because it is in fact (mod H)-Nielsen number, as can be seen below. For the sake of simplicity, we omit the index H in the following sections.

REMARK 3.4 (Important). We have a counter-example in [24] (cf. [22, Example 10.1 in Chapter I.10]) that, under the above assumptions (i)–(iii), the Nielsen number $N(\varphi)$ is rather the topological invariant for the number of essential classes of coincidences than of fixed points. On the other hand, for a compact X and $q = \mathrm{id}$, $N(\varphi)$ gives even without (ii) a lower estimate of the number of fixed points of φ (see [5]), i.e. $N(\varphi) \leqslant \#\mathrm{Fix}(\varphi)$, where $\mathrm{Fix}(\varphi) := \mathrm{card}\{x \in X \mid x \in \varphi(x)\}$. We have conjectured in [38] that if $\varphi = q \circ p^{-1}$ assumes only simply connected values, then also $N(\varphi) \leqslant \#\mathrm{Fix}(\varphi)$.

The following sketch demonstrates how subtle is the definition of the Nielsen number for multivalued maps. Let

$$X \xLeftarrow{p_0} \Gamma \xrightarrow{q_0} Y \quad \text{and} \quad X \xLeftarrow{p_1} \Gamma \xrightarrow{q_1} Y$$

be two admissible maps.

If $(p_0, q_0) \sim (p_1, q_1)$, i.e. if (p_0, q_0) is admissibly homotopic to (p_1, q_1) (see Definition 2.6), and $h: Y \to Z$ is a continuous map, then we write $(p_0, hq_0) \sim (p, hq)$. We say that a multivalued map $X \xLeftarrow{p} \Gamma \xrightarrow{q} Y$ *represents a single-valued map* $\rho: X \to Y$ if $q = p\rho$. Now, we assume that $X = Y$ and we are going to estimate the cardinality of the coincidence set

$$C(p,q) := \bigl\{z \in \Gamma \mid p(z) = q(z)\bigr\}.$$

We begin by defining a Nielsen-type relation on $C(p,q)$. This definition requires the following conditions on $X \xLeftarrow{p} \Gamma \xrightarrow{q} Y$:

(i′) X, Y are connected, locally contractible metric spaces (observe that then they admit universal coverings),

(iii′) $p: \Gamma \Longrightarrow X$ is a Vietoris map,

(iii″) for any $x \in X$, the restriction $q_1 = q|_{p^{-1}(x)}: p^{-1}(x) \to Y$ admits a lift $\widetilde{q}_1$ to the universal covering space $(p_Y: \widetilde{Y} \to Y)$:

$$\begin{tikzcd}
 & \widetilde{Y} \arrow[d, Rightarrow, "p_Y"] \\
p^{-1}(x) \arrow[ur, dashed, "\widetilde{q}_1"] \arrow[r, "q_1"'] & Y
\end{tikzcd}$$

Let us note that the following implications hold: (i) $\Rightarrow$ (i′), (iii) $\Rightarrow$ (iii′), (iii″).

Consider a single-valued map $\rho: X \to Y$ between two spaces admitting universal coverings $p_X: \widetilde{X} \Rightarrow X$ and $p_Y: \widetilde{X} \Rightarrow Y$. Let $\theta_X = \{\alpha: \widetilde{X} \to \widetilde{X} \mid p_X\alpha = p_X\}$ be the group of natural transformations of the covering p_X. Then the map ρ admits a lift $\widetilde{\rho}: \widetilde{X} \to \widetilde{Y}$. We can define a homomorphism $\widetilde{\rho}_!: \theta_X \to \theta_Y$ by the equality

$$\widetilde{q}(\alpha \cdot \widetilde{x}) = \widetilde{q}_!(\alpha)\widetilde{q}(\widetilde{x}) \quad \bigl(\alpha \in \theta_X, \widetilde{x} \in \widetilde{X}\bigr).$$

It is well known that there is an isomorphism between the fundamental group $\pi_1(X)$ and θ_X which may be described as follows. We fix points $x_0 \in X$, $\widetilde{x} \in \widetilde{X}$ and a loop $\omega : I \to X$ based at x_0. Let $\widetilde{\omega}$ denote the unique lift of ω starting from $\widetilde{x}_0$. We subordinate to $[\omega] \in \pi_1(X, x_0)$ the unique transformation from θ_X sending $\widetilde{\omega}(0)$ to $\widetilde{\omega}(1)$. Then the homomorphism $\widetilde{\rho}_! : \theta_X \to \theta_Y$ corresponds to the induced homomorphism between the fundamental groups $\rho_\# : \pi_1(X, x_0) \to \pi_1(Y, \rho(x_0))$.

It can be shown that, under the assumptions (i$'$), (iii$'$), (iii$''$), a multivalued map (p, q) admits a lift to a multivalued map between the universal coverings. These lifts will split the coincidence set $C(p, q)$ into Nielsen classes. Besides that the pair (p, q) induces a homomorphism $\theta_X \to \theta_Y$ giving the Reidemeister set.

We start with the following lemma.

LEMMA 3.4. *Suppose we are given Y, a locally contractible metric space, Γ a metric space, $\Gamma_0 \subset \Gamma$ a compact subspace, $q : \Gamma \to Y$, $\widetilde{q}_0 : \Gamma_0 \to Y$ continuous maps for which the diagram*

$$\begin{tikzcd}
\Gamma_0 \arrow[r, "\widetilde{q}_0"] \arrow[d, "i"'] & \widetilde{Y} \arrow[d, "p_Y"] \\
\Gamma \arrow[r, "q"'] & Y
\end{tikzcd}$$

commutes (here, $p_Y : \widetilde{Y} \to Y$ denotes the universal covering). In other words, $\widetilde{q}_0$ is a partial lift of q. Then $\widetilde{q}_0$ admits an extension to a lift onto an open neighbourhood of Γ_0 in Γ.

Consider again a multivalued map $X \xleftarrow{p} \Gamma \xrightarrow{q} Y$ satisfying (i$'$). Define (a pullback)

$$\widetilde{\Gamma} = \big\{(\widetilde{x}, z) \in \widetilde{X} \times \Gamma \mid p_X(\widetilde{x}) = p(z)\big\}.$$

Now, we can apply Lemma 3.4 to the multivalued map $\widetilde{X} \overset{\widetilde{p}}{\Longleftarrow} \widetilde{\Gamma} \xrightarrow{qp_\Gamma} Y$, and so we get a lift $\widetilde{q} : \widetilde{\Gamma} \to \widetilde{Y}$ such that the diagram

$$\begin{tikzcd}
\widetilde{X} \arrow[d, "p_X"'] & \widetilde{\Gamma} \arrow[l, Rightarrow, "\widetilde{p}"'] \arrow[r, "\widetilde{q}"] \arrow[d, "p_\Gamma"'] & \widetilde{Y} \arrow[d, "p_Y"] \\
X & \Gamma \arrow[l, Rightarrow, "p"] \arrow[r, "q"'] & Y
\end{tikzcd}$$

is commutative, where $\widetilde{p}(\widetilde{x}, z) = \widetilde{x}$ and $p_\Gamma(\widetilde{x}, z) = z$. Let us note that the lift $\widetilde{p}$ is given by the above formula, but $\widetilde{q}$ is not precised. We fix such a $\widetilde{q}$.

Observe that $p:\Gamma \Longrightarrow X$ and the lift $\widetilde{p}$ induce a homomorphism $\widetilde{p}^!:\theta_X \to \theta_\Gamma$ by the formula $\widetilde{p}^!(\alpha)(\widetilde{x},z)=(\alpha\widetilde{x},z)$. It is easy to check that the homomorphism $\widetilde{p}^!$ is an isomorphism (any natural transformation of $\widetilde{\Gamma}$ is of the form $\alpha\cdot(\widetilde{x},z)=(\alpha\widetilde{x},z)$) and that $\widetilde{p}^!$ is inverse to $\widetilde{p}_!$. Recall that the lift $\widetilde{q}$ defines a homomorphism $\widetilde{q}_!:\theta_\Gamma \to \theta_Y$ by the equality $\widetilde{q}(\lambda)=\widetilde{q}_!(\lambda)\widetilde{q}$.

In the sequel, we will consider the composition $\widetilde{q}_!\widetilde{p}^!:\theta_X \to \theta_Y$.

LEMMA 3.5. *Let a multivalued map* (p,q) *satisfying* (i′) *represent a single-valued map* ρ, *i.e.* $q=\rho p$. *Let* $\widetilde{\rho}$ *be the lift of* ρ *which satisfies* $\widetilde{q}=\widetilde{\rho}\widetilde{p}$. *Then* $\widetilde{\rho}_!\widetilde{p}^!=\rho_!$.

Now, we are in a position to define the Nielsen classes. Consider a multivalued self-map $X \overset{p}{\Longleftarrow} \Gamma \xrightarrow{q} X$ satisfying (i′). By the above consideration, we have a commutative diagram

$$\begin{tikzcd}
\widetilde{\Gamma} \arrow[r, "\widetilde{p},\widetilde{q}"] \arrow[d, "p_\Gamma"'] & \widetilde{X} \arrow[d, "p_X"] \\
\Gamma \arrow[r, "p,q"] & X
\end{tikzcd}$$

Following the single-valued case (see, e.g., [77]), we can prove (see [24] and cf. [22]) the following lemma.

LEMMA 3.6.
- $C(p,q)=\bigcup_{\alpha\in\theta_X} p_\Gamma C(\widetilde{p},\alpha\widetilde{q})$,
- *if* $p_\Gamma C(\widetilde{p},\alpha\widetilde{q})\cap p_\Gamma C(\widetilde{p},\beta\widetilde{q})$ *is not empty, then there exists a* $\gamma\in\theta_X$ *such that* $\beta=\gamma\circ\alpha\circ(\widetilde{q}_!\widetilde{p}^!\gamma)^{-1}$,
- *the sets* $p_\Gamma C(\widetilde{p},\alpha\widetilde{q})$ *are either disjoint or equal.*

Define an action of θ_X on itself by the formula $\gamma\circ\alpha=\gamma\alpha(\widetilde{q}_!p^!\gamma)$. The quotient set will be called the *set of Reidemeister classes* and will be denoted by $R(p,q)$. The above lemma defines an injection:

$$\text{set of Nielsen classes} \to R(p,q),$$

given by $A \to [\alpha]\in R(p,q)$, where $\alpha\in\theta_X$ satisfies $A=p_\Gamma(C(\widetilde{p},\alpha\widetilde{q}))$.

One can prove that our definition does not depend on $\widetilde{q}$.

Let us recall that the homomorphism $\widetilde{q}_!:\theta_\Gamma \to \theta_Y$ is defined by the relation $\widetilde{q}\alpha=\widetilde{q}_!(\alpha)\widetilde{q}$, for $\alpha\in\theta_\Gamma$. If $\widetilde{q}'=\gamma\widetilde{q}$ is another lift of q ($\widetilde{\gamma}\in\theta_\Gamma$), then the induced homomorphism $\widetilde{q}'_!:\theta_\Gamma \to \theta_Y$ is defined by the relation $\widetilde{q}'\alpha=\widetilde{q}'_!(\alpha)\widetilde{q}'$.

One can also show that the Reidemeister sets obtained by different lifts of q are canonically isomorphic. That is why we write $R(p,q)$ omitting tildes.

PROPOSITION 3.1. *If* $X\times[0,1] \xleftarrow{p} \Gamma \xrightarrow{q} Y$ *is a homotopy satisfying* (i′), (iii′), (iii″), *then the homomorphism* $\widetilde{q}_{t!}\widetilde{p}_t^!:\theta_X \to \theta_Y$ *does not depend on* $t\in[0,1]$, *where the lifts used* *in the definitions of these homomorphisms are restrictions of some fixed lifts* p, q *of the given homotopy.*

REMARK 3.5. If (p,q) represents a single-valued map $\rho : X \to Y$ ($q = \rho p$), then $\widetilde{q}_! \widetilde{p}^!$ equals $\widetilde{\rho}_!$ (here the chosen lifts satisfy $\widetilde{q} = \widetilde{\rho}\widetilde{p}$).

Let us point out that the above theory can be modified into the relative case (i.e. modulo a normal subgroup $H \subset \theta_X$). The index H will denote the relative modification.

Assuming $X = Y$, we can give

LEMMA 3.7.
- (i) $C(p,q) = \bigcup_{\alpha \in \theta_{XH}} p_{\Gamma_H} C(\widetilde{p}_H, \alpha\widetilde{q}_H)$,
- (ii) *if* $p_{\Gamma_H} C(\widetilde{p}_H, \alpha\widetilde{q}_H) \cap p_{\Gamma_H} C(\widetilde{p}_H, \beta\widetilde{q}_H)$ *is not empty, then there exists a* $\gamma \in \theta_{XH}$ *such that* $\beta = \gamma \circ \alpha \circ (\widetilde{q}_{H!} \widetilde{p}^!_H \gamma)^{-1}$,
- (iii) *the sets* $p_{\Gamma_H} C(\widetilde{p}_H, \alpha\widetilde{q}_H)$ *are either disjoint or equal.*

Hence, we get the splitting of $C(p,q)$ into the H-Nielsen classes and the natural injection from the set of H-Nielsen classes into the set of Reidemeister classes modulo H, namely, $R_H(p,q)$.

Now, we would like to exhibit the classes which do not disappear under any compact (admissible) homotopy. For this, we need however (besides (i′), (iii′), (iii″)) the following two assumptions on the pair $X \overset{p}{\Longleftarrow} \Gamma \xrightarrow{q} Y$:
- (i″) Let X be a connected ANR-space, e.g., a connected retract of an open subset of (a convex set in) a Fréchet space, p is a Vietoris map and $\mathrm{cl}(q(\Gamma)) \subset X$ is compact, i.e. q is a compact map.
- (ii′) There exists a normal subgroup $H \subset \theta_X$ of a finite index satisfying $\widetilde{q}_! \widetilde{p}^!(H) \subset H$.

Let us note that the following implications hold: (i), (ii) ⇒ (ii′), (i), (iii) ⇒ (i″).

DEFINITION 3.1. We call a pair (p,q) *N-admissible* if it satisfies (i′), (i″), (ii′), (iii′), (iii″) (⇐ (i)–(iii)).

Let us recall that, under the assumption (ii′), the Lefschetz number $\Lambda(p,q) \in \mathbb{Q}$ is defined (see Section 3.1). This is a homotopy invariant (with respect to the homotopies satisfying (ii′)) and $\Lambda(p,q) \neq 0$ implies $C(p,q) \neq \emptyset$ (cf. Section 3.1).

Let $A = p_{\Gamma_H} C(\widetilde{p}, \alpha\widetilde{q})$ be a Nielsen class of an N-admissible pair (p,q). We say that (the N-Nielsen class) A is *essential* if $\Lambda(\widetilde{p}, \alpha\widetilde{q}) \neq 0$. This definition it correct, i.e. does not depend on the choice of α.

DEFINITION 3.2. Let (p,q) be an N-admissible multivalued map (for a subgroup $H \subset \theta_X$). We define the *Nielsen number modulo H* as the number of essential classes in θ_{X_H}. We denote this number by $N_H(p,q)$.

The following theorem is an easy consequence of the homotopy invariance of the Lefschetz number.

THEOREM 3.4. *$N_H(p,q)$ is a homotopy invariant (with respect to N-admissible homotopies*

$$X \times [0,1] \xLeftarrow{p} \Gamma \xrightarrow{q} X).$$

Moreover, (p,q) has at least $N_H(p,q)$ coincidences.

The following theorem shows that the above definition is consistent with the classical Nielsen number for single-valued maps.

THEOREM 3.5. *If an N-admissible map (p,q) is N-admissibly homotopic to a pair (p',q'), representing a single-valued map p (i.e. $q' = \rho p'$), then (p,q) has at least $N_H(\rho)$ coincidences (here H denotes also the subgroup of $\pi_1 X$ corresponding to the given $H \subset \theta_X$ in* (ii$'$)).

Although in the general case the theory requires special assumptions on the considered pair (p,q), in the case of multivalued self-maps on a torus it is enough to assume that this pair satisfies only (i$''$), i.e. it is admissible. This is due to the fact that any pair satisfying (i$''$) is homotopic to a pair representing a single-valued map.

THEOREM 3.6. *Any multivalued self-map (p,q) on the torus satisfying* (i$''$) *is admissibly homotopic to a pair representing a single-valued map.*

THEOREM 3.7. *Let $\mathbb{T}^n \xLeftarrow{p} \Gamma \xrightarrow{q} \mathbb{T}^n$ be such that p is a Vietoris map. Let $\rho : \mathbb{T}^n \to \mathbb{T}^n$ be a single-valued map representing a multivalued map homotopic to (p,q) (according to Theorem* 3.6, *such a map always exists). Then (p,q) has at least $N(\rho)$ coincidences.*

REMARK 3.6. Let us also recall that, on the torus $\mathbb{T}^n$, $N(\rho) = |\Lambda(\rho)| = |\det(I - A)|$, where A is an integer $(n \times n)$-matrix representing the induced homotopy homomorphism $\rho_\# : \pi_1 \mathbb{T}^n \to \pi_1 \mathbb{T}^n$. Moreover, if $\det(I - A) \neq 0$, then

$$\operatorname{card}\big(\pi_1(\mathbb{T}^n) / \operatorname{Im}(\rho_\#)\big) = \big|\det(I - A)\big|.$$

In particular, for $\rho = \mathrm{id}$, we have

$$N(\mathrm{id}) = \big|\Lambda(\mathrm{id})\big| = \big|\chi(\mathbb{T}^n)\big| = |\det O| = 0,$$

while for $\rho = -\mathrm{id}$, we have $N(-\mathrm{id}) = |\Lambda(-\mathrm{id})| = |\det 2I| = 2^n$.

For more details, see [22,12].

3.3. *Fixed point index theorems*

Consider a multivalued map $\varphi : X \multimap X$ and assume, similarly as in Section 3.1, that

(i) X is ANR-space, e.g., a retract of an open subset of a convex set in a Fréchet space,

(ii) φ is a compact composition of an R_δ-map $\Phi : X \multimap Y$ and a continuous single-valued map $f : Y \to X$, namely $\varphi = f \circ \Phi$, where Y is an ANR-space.

Let $D \subset X$ be an open subset of X with no fixed points of φ on its boundary ∂D. Then and integer $\operatorname{ind}(\varphi, X, D)$, called the *fixed point index* over X w.r.t. D exists such that the following proposition holds (see, e.g., [12,22,44]).

PROPOSITION 3.2. *Let $\varphi : X \multimap X$ be a map satisfying* (i), (ii). *Then* $\operatorname{ind}(\varphi, X, D) \in \mathbb{Z}$ *is well-defined satisfying the following properties*:

- (Existence) *If* $\operatorname{ind}(\varphi, X, D) \neq 0$, *then* $\operatorname{Fix}(\varphi) \neq \emptyset$.
- (Localization) *If $D_1 \subset D$ are open subsets of X such that* $\operatorname{Fix}(\varphi) \subset D_1 \subset D$, *then*

$$\operatorname{ind}(\varphi, X, D) = \operatorname{ind}(\varphi, X, D_1).$$

- (Additivity) *If D_j, $j = 1, \dots, n$, are open disjoint subsets of D and all fixed points of $\varphi|_D$ are located in $\bigcup_{j=1}^n D_j$, then* $\operatorname{ind}(\varphi, X, D_j)$, $j = 1, \dots, n$, *are well-defined satisfying*

$$\operatorname{ind}(\varphi, X, D) = \sum_{j=1}^{n} \operatorname{ind}(\varphi, X, D_j).$$

- (Homotopy) *If there is a compact homotopy $\chi : X \times [0, 1] \multimap X$ (in the same class of maps under consideration) with $\chi(\cdot, 0) = \varphi$, $\chi(\cdot, 1) = \psi$, and ∂D is fixed point free w.r.t. χ, then*

$$\operatorname{ind}(\varphi, X, D) = \operatorname{ind}(\psi, X, D).$$

- (Multiplicity) *If $\psi : \widetilde{X} \multimap \widetilde{X}$ satisfies* (i), (ii) *and an open $\widetilde{D} \subset \widetilde{X}$ is fixed point free w.r.t. ψ, then*

$$\operatorname{ind}\bigl(\varphi \times \psi, X \times \widetilde{X}, D \times \widetilde{D}\bigr) = \operatorname{ind}(\varphi, X, D) \cdot \operatorname{ind}\bigl(\psi, \widetilde{X}, \widetilde{D}\bigr).$$

- (Contraction) *If $X' \subset X$ are ANR-spaces such that $\varphi(X) \subset X'$ and $\varphi|_{X'}$ satisfies* (ii) *with* $\operatorname{Fix}(\varphi|_{X'}) \cap \partial(D \cap X') = \emptyset$, *then*

$$\operatorname{ind}(\varphi, X, D) = \operatorname{ind}\bigl(\varphi|_{X'}, X', D \cap X'\bigr).$$

- (Normalization) *If $X = D$, then*

$$\operatorname{ind}(\varphi, X, D) = \operatorname{ind}(\varphi, X, X) = \Lambda(\varphi).$$

Because of possible applications, it is very useful to formulate sufficiently general continuation principles.

For compact admissible maps from open subsets of a neighbourhood retract of a Fréchet space E into E, the fixed point index was just indicated.

Now, we will apply Proposition 3.2 to formulating the appropriate continuation principles. We restrict ourselves only to a particular class of admissible maps, namely to R_δ-maps $\Phi : D \multimap E$ (written here $\Phi \in J(D, E)$), i.e. u.s.c. maps with R_δ-values.

We often need to study fixed points for maps defined on sufficiently fine sets (possibly with an empty interior), but with values out of them. Making use of the previous results, we are in position to make the following construction.

Assume that X is a retract of a Fréchet space E and D is an open subset of X. Let $\Phi \in J(D, E)$ be locally compact, $\mathrm{Fix}(\Phi)$ be compact and let the following condition hold:

$$\forall x \in \mathrm{Fix}(\Phi)\ \exists U_x \ni x,\ U_x \text{ is open in } D \text{ such that } \Phi(U_x) \subset X. \tag{A}$$

The class of locally compact J-maps from D to E with the compact fixed point set and satisfying (A) will be denoted by the symbol $J_A(D, E)$. We say that $\Phi, \Psi \in J_A(D, E)$ are *homotopic in* $J_A(D, E)$ if there exists a homotopy $H \in J(D \times [0, 1], E)$ such that $H(\cdot, 0) = \Phi$, $H(\cdot, 1) = \Psi$, for every $x \in D$, there is an open neighbourhood V_x of x in D such that $H|_{V_x \times [0,1]}$ is compact, and

$$\forall x \in D\ \forall t \in [0, 1]$$
$$\big[x \in H(x, t) \Rightarrow \exists U_x \ni x,\ U_x \text{ is open in } D,\ H\big(U_x \times [0, 1]\big) \subset X\big]. \tag{A$_H$}$$

Note that the condition (A_H) is equivalent to the following one:

- If $\{x_j\}_{j \geqslant 1} \subset D$ converges to $x \in H(x, t)$, for some $t \in [0, 1]$, then $H(\{x_j\} \times [0, 1]) \subset X$, for j sufficiently large.

Let $\Phi \in J_A(D, E)$. Then $\mathrm{Fix}(\Phi) \subset \bigcup\{U_x \mid x \in \mathrm{Fix}(\Phi)\} \cap V =: D' \subset D$ and $\Phi(D') \subset X$, where V is a neighbourhood of the set $\mathrm{Fix}(\Phi)$ such that $\Phi|_V$ is compact (by the compactness of $\mathrm{Fix}(\Phi)$ and local compactness of Φ) and U_x is a neighbourhood of x as in (A). Define

$$\mathrm{Ind}_A(\Phi, X, D) = \mathrm{ind}\big(\Phi|_{D'}, X, D'\big),$$

where $\mathrm{ind}(\Phi|_{D'}, X, D')$ is defined as in Proposition 3.2. This definition is independent of the choice of D'.

In the following theorem, we give some properties of Ind_A which will be used in the proof of the continuation Theorem 3.8. The simple proof is omitted.

PROPOSITION 3.3.

(i) (Existence) *If* $\mathrm{Ind}_A(\Phi, X, D) \neq 0$, *then* $\mathrm{Fix}(\Phi) \neq \emptyset$.

(ii) (Localization) *If* $D_1 \subset D$ *are open subsets of a retract* X *of a space* E, $\Phi \in J_A(D, E)$ *is compact, and* $\mathrm{Fix}(\Phi)$ *is a compact subset of* D_1, *then*

$$\mathrm{Ind}_A(\Phi, X, D) = \mathrm{Ind}_A(\Phi, X, D_1).$$

(iii) (Homotopy) *If* H *is a homotopy in* $J_A(D, E)$, *then*

$$\mathrm{Ind}_A\big(H(\cdot, 0), X, D\big) = \mathrm{Ind}_A\big(H(\cdot, 1), X, D\big).$$

(iv) (Normalization) *If* $\Phi \in J(X)$ *is a compact map, then* $\mathrm{Ind}_A(\Phi, X, X) = 1$.

THEOREM 3.8 (Continuation principle). *Let* X *be a retract of a Fréchet space* E, D *be an open subset of* X *and* H *be a homotopy in* $J_A(D, E)$ *such that*

(i) $H(\cdot, 0)(D) \subset X$,

(ii) *there exists* $H' \in J(X)$ *such that* $H'|_D = H(\cdot, 0)$, H' *is compact and* $\mathrm{Fix}(H') \cap (X \setminus D) = \emptyset$.

Then there exists $x \in D$ *such that* $x \in H(x, 1)$.

PROOF. Applying the localization property (ii), we obtain

$$\mathrm{Ind}_A\bigl(H(\cdot, 0), X, D\bigr) = \mathrm{Ind}_A\bigl(H(\cdot, 0), X, X\bigr).$$

By the normalization property (iv), $\mathrm{Ind}_A(H(\cdot, 0), X, X) = 1$. Thus, by the homotopy property (iii), $\mathrm{Ind}_A(H(\cdot, 0), X, D) = \mathrm{Ind}_A(H(\cdot, 1), X, D) = 1$, which implies by (i) that $H(\cdot, 1)$ has a fixed point. □

COROLLARY 3.1. *Let* X *be a retract of a Fréchet space* E *and* H *be a homotopy in* $J_A(X, E)$ *such that* $H(x, 0) \subset X$, *for every* $x \in X$, *and* $H(\cdot, 0)$ *is compact. Then* $H(\cdot, 1)$ *has a fixed point.*

COROLLARY 3.2. *Let* X *be a retract of a Fréchet space* E, D *be an open subset of* X *and* H *be a homotopy in* $J_A(D, E)$. *Assume that* $H(x, 0) = x_0$, *for every* $x \in D$. *Then there exists* $x \in D$ *such that* $x \in H(x, 1)$.

COROLLARY 3.3. *Let* X *be a retract of a Fréchet space* E *and* $\Phi \in J(X)$ *be compact. Then* Φ *has a fixed point.*

REMARK 3.7. If $E = X$ is a Banach space, then it follows from Proposition 3.2 that the "pushing" condition (A_H), related to $J_A(D, E)$, can be reduced to $\mathrm{Fix}(\varphi) \cap \partial D \neq \emptyset$.

Some applications motivate us to consider weaker than (A_H) condition on H. Unfortunately, we cannot use the fixed point index technique described above. The proof of the following theorem is based on a Schauder-type approximation technique (for more details, see [19,22]).

THEOREM 3.9 (Continuation principle). *Let* X *be a closed, convex subset of a Fréchet space* E *and let* $H \in J(X \times [0, 1], E)$ *be compact. Assume that*

(i) $H(x, 0) \subset X$, *for every* $x \in X$,

(ii) *for any* $(x, t) \in \partial X \times [0, 1)$ *with* $x \in H(x, t)$, *there exist open neighbourhoods* U_x *of* x *in* X *and* I_t *of* t *in* $[0, 1)$ *such that* $H((U_x \cap \partial X) \times I_t) \subset X$.

Then there exists a fixed point of $H(\cdot, 1)$.

REMARK 3.8. Note that the convexity of X in Theorem 3.9 is essential only in the infinite-dimensional case. For the proof, we have namely to intersect X with a finite-dimensional subspace L.

Now, we would like to consider condensing maps. Hence, let this time $\varphi : X \multimap X$ be a multivalued map such that

(I) X is a closed, convex subset of a Fréchet space E,

(II) φ is a condensing composition of an R_δ-map $\Phi : X \multimap Y$ and a continuous single-valued map $f : Y \to X$, namely $\varphi = f \circ \Phi$, where Y is an ANR-space.

Assume that $\mathrm{Fix}(\varphi) \cap \partial D \neq \emptyset$, for some open subset $D \subset X$. Since φ is condensing, it has a nonempty compact fundamental set T (see Definition 2.11 and Proposition 2.7(iii)). Let $\mathrm{ind}(\varphi, X, D) = 0$, whenever $\mathrm{Fix}(\varphi) = \emptyset$. Since T is an AR-space, we may choose a retraction $r : X \to T$ in order to define the fixed point index, for the composition

$$\widetilde{\varphi} : \overline{D} \cap T \overset{\Phi}{\multimap} Y \overset{r \circ f}{\multimap} T,$$

by putting

$$\mathrm{ind}(\varphi, X, D) := \mathrm{ind}\big(\widetilde{\varphi}, \widetilde{X}, D \cap T\big),$$

where ind on the right-hand side is defined as in Proposition 3.2. This correct definition is independent of the chosen fundamental set, and so the index has all the appropriate properties as in Proposition 3.2, but (see Remark 3.2 and cf. [37]) the normalization property. Instead of it, a weak normalization property can be formulated as follows:

- (Weak normalization) If f in $\varphi = f \circ \Phi$ is a constant map, i.e. $f(y) = a \notin \partial D$, for each $y \in Y$, then

$$\mathrm{ind}(\varphi, X, D) = \begin{cases} 1, & \text{for } a \in D, \\ 0, & \text{for } a \notin D. \end{cases}$$

As already pointed out above, in the applications of the fixed point theory, we often need to consider maps with values in a Fréchet space and not in a closed convex set. We will also extend our theory to this case.

Again, let E be a Fréchet space and X be a closed and convex subset of E. Let $U \subset X$ be open and consider the map $\varphi \in J_A(U, E)$, where the symbol $J_A(U, E)$ is again reserved for J-maps from U to E satisfying condition (A). The notion of homotopy in J_A will be understood analogously. Thus, $\mathrm{Fix}(\varphi)$ is compact and φ has a compact fundamental set T (see Section 2.3). Set $\mathrm{Ind}_A(\varphi, X, U) = 0$, whenever $\mathrm{Fix}(\varphi) = \emptyset$. Otherwise, let $x_1, \dots, x_n \in \mathrm{Fix}(\varphi)$ such that $\mathrm{Fix}(\varphi) \subset \bigcup_{i=1}^n U_{x_i} =: V$, where U_{x_i} are neighbourhoods of x_i such that $\overline{U}_{x_i} \subset U$ and satisfy condition (A). Then $\varphi|_V : V \multimap X$ is a J-map with compact fundamental set T and satisfies $\mathrm{Fix}(\varphi) \cap \partial V = \emptyset$. Thus, we can define

$$\mathrm{Ind}_A(\varphi, X, U) := \mathrm{ind}(\varphi|_{\overline{V}}, X, V).$$

The independence of this definition of the chosen set V follows from the additivity property. Furthermore, if $\varphi : \overline{U} \multimap X$ has a compact fundamental set and $\mathrm{Fix}(\varphi) \cap \partial U = \emptyset$, then $\mathrm{Ind}_A(\varphi, X, U)$ is defined and

$$\mathrm{Ind}_A(\varphi, X, U) = \mathrm{ind}(\varphi, X, U).$$

The following proposition easily follows from the above argumentation.

PROPOSITION 3.4.

(i) (Existence) *If* $\mathrm{Ind}_A(\varphi, X, U) \neq 0$, *then* $\mathrm{Fix}(\varphi) \neq \emptyset$.

(ii) (Additivity) *Let* $\mathrm{Fix}(\varphi) \subset U_1 \cup U_2$, *where* U_1, U_2 *are open disjoint subsets of* U. *Then*

$$\mathrm{Ind}_A(\varphi, X, U) = \mathrm{Ind}_A(\varphi|_{U_1}, X, U_1) + \mathrm{Ind}_A(\varphi|_{U_2}, X, U_2).$$

(iii) (Homotopy) *Let* $\psi : U \multimap E$ *be homotopic in* J_A *to the map* φ. *Assume that the homotopy* $\chi : U \times [0,1] \multimap E$ *has a compact fundamental set and the set*

$$\Sigma := \big\{(x,t) \in U \times [0,1] \mid x \in \chi(x,t)\big\}$$

is compact. Then

$$\mathrm{Ind}_A(\varphi, X, U) = \mathrm{Ind}_A(\psi, X, U).$$

(iv) (Weak normalization) *Assume that* $\varphi : U \to E$ *is a constant map* $\varphi(x) = a \in E$, *for all* $x \in U$. *Then*

$$\mathrm{Ind}_A(\varphi, X, U) = \begin{cases} 1, & \text{for } a \in U, \\ 0, & \text{for } a \notin U. \end{cases}$$

Using Proposition 3.4, we can easily formulate a continuation principle which is convenient for various applications.

THEOREM 3.10 (Continuation principle). *Let* X *be a closed, convex subset of a Fréchet space* E, *let* $U \subset X$ *be open and let* $\chi : U \times [0,1] \multimap E$ *be a homotopy in* J_A *such that* Σ (*see* (iii) *above*) *is compact. Let* χ *be condensing and assume that there is a condensing* $\varphi \in J(X)$ *such that* $\varphi|_U = \chi(\cdot, 0)$ *and* $\mathrm{Fix}(\varphi) \cap (X \setminus U) = \emptyset$. *Then* $\chi(\cdot, 1)$ *has a fixed point.*

PROOF. The proof follows, in view of the existence property (i) in Proposition 3.4, from the following equations:

$$\mathrm{Ind}_A\big(\chi(\cdot,1), X, U\big) = \mathrm{Ind}_A\big(\chi(\cdot,0), X, U\big),$$

by the homotopy property (iii),

$$\mathrm{Ind}_A\big(\chi(\cdot,0), X, U\big) = \mathrm{Ind}_A(\varphi|_U, X, U) = \mathrm{Ind}_A(\varphi, X, X),$$

by the additivity property (ii). Finally, we see that

$$\mathrm{Ind}_A(\varphi, X, X) = \mathrm{ind}(\varphi, X, X) = 1. \qquad \square$$

COROLLARY 3.4. *Let* $\chi : X \times [0,1] \multimap E$ *be a condensing homotopy in* J_A *such that* $\chi(x,0) \subset X$, *for every* $x \in X$. *Then* $\chi(\cdot,1)$ *has a fixed point.*

REMARK 3.9. If $E = X$ is a Banach space, then it follows from the properties of the above fixed point index $\operatorname{ind}(\chi, X, D)$ that the "pushing" condition (A_H), related to $J_A(D, E)$, can be reduced to $\operatorname{Fix}(\chi) \cap \partial D \neq \emptyset$. If, in particular, $U \subset E$ is an open convex subset such that $\chi(\cdot,0) = \varphi|_U : U \multimap U$, then the same is true even without requiring $\operatorname{Fix}(\varphi) \cap (X \setminus U) = \emptyset$.

4. General methods for solvability of boundary value problems

4.1. *Continuation principles to boundary value problems*

In this part, fixed point principles in Section 3 will be applied to differential equations and inclusions.

At first, we are interested in the existence problems for ordinary differential equations and inclusions in Euclidean spaces on not necessarily compact intervals. Let us start with some definitions.

Let J be an interval in $\mathbb{R}$. We say that a map $x : J \to \mathbb{R}^n$ is *locally absolutely continuous* if x is absolutely continuous on every compact subset of J. The set of all locally absolutely continuous maps from J to $\mathbb{R}^n$ will be denoted by $\mathrm{AC}_{\mathrm{loc}}(J, \mathbb{R}^n)$.

Consider the inclusion

$$\dot{x} \in F(t,x), \tag{4.1}$$

where F is a set-valued *u-Carathéodory map*, i.e. it has i.a. the following properties:

- the set of values of F is nonempty, compact and convex, for all $(t,x) \in J \times \mathbb{R}^n$,
- the map $F(t,\cdot)$ is u.s.c., for almost all $t \in J$,
- the map $F(\cdot,x)$ is measurable, for all $x \in \mathbb{R}^n$.

By a *solution* of the inclusion (4.1), we mean a locally absolutely continuous function x such that (4.1) holds, for almost all $t \in J$.

We recall two known results which are needed in the sequel.

PROPOSITION 4.1 (Cf. [42, Theorem 0.3.4] and Lemma 4.4 below). *Assume that the sequence of absolutely continuous functions* $x_k : K \to \mathbb{R}^n$ (*K is a compact interval*) *satisfies the following conditions*:

- *the set* $\{x_k(t) \mid k \in \mathbb{N}\}$ *is bounded, for every* $t \in K$,
- *there is an integrable function* (*in the sense of Lebesgue*) $\alpha : K \to \mathbb{R}$ *such that*

$$\left|\dot{x}_k(t)\right| \leqslant \alpha(t), \quad \text{for a.a. } t \in K \text{ and for all } k \in \mathbb{N}.$$

Then there exists a subsequence (*denoted just the same*) $\{x_k\}$ *convergent to an absolutely continuous function* $x : K \to \mathbb{R}^n$ *in the following sense*:

(i) $\{x_k\}$ *uniformly converges to* x, *and*
(ii) $\{\dot{x}_k\}$ *weakly converges in* $L^1(K, \mathbb{R}^n)$ *to* $\dot{x}$.

The second one is the well-known (see, e.g., [22, Theorem 1.33 in Chapter I.1]) Mazur theorem.

The following result is crucial.

PROPOSITION 4.2. *Let* $G : J \times \mathbb{R}^n \times \mathbb{R}^m \multimap \mathbb{R}^n$ *be a u-Carathéodory map and let* S *be a nonempty subset of* $\mathrm{AC}_{\mathrm{loc}}(J, \mathbb{R}^n)$. *Assume that*

(i) *there exists a subset* Q *of* $C(J, \mathbb{R}^n)$ *such that, for any* $q \in Q$, *the set* $T(q)$ *of all solutions of the boundary value problem*

$$\begin{cases} \dot{x}(t) \in G\big(t, x(t), q(t)\big), & \text{for a.a. } t \in J, \\ x \in S \end{cases} \tag{4.2}$$

is nonempty,

(ii) $T(Q)$ *is bounded in* $C(J, \mathbb{R}^n)$,

(iii) *there exists a locally integrable function* $\alpha : J \to \mathbb{R}$ *such that*

$$\big|G\big(t, x(t), q(t)\big)\big| = \sup\big\{|y| \mid y \in G\big(t, x(t), q(t)\big)\big\} \leqslant \alpha(t), \quad \text{a.e. in } J,$$

for any pair $(q, x) \in \Gamma_T$, *where* Γ_T *denotes the graph of* T.

Then $T(Q)$ *is a relatively compact subset of* $C(J, \mathbb{R}^n)$. *Moreover, under the assumptions* (i)–(iii), *the multivalued operator* $T : Q \multimap S$ *is u.s.c. with compact values if and only if the following condition is satisfied*:

(iv) *given a sequence* $\{(q_k, x_k)\} \subset \Gamma_T$, *if* $\{(q_k, x_k)\}$ *converges to* (q, x) *with* $q \in Q$, *then* $x \in S$.

PROOF. For the relative compactness of $T(Q)$, it is sufficient to show that all elements of $T(Q)$ are equicontinuous.

By (iii), for every $x \in T(Q)$, we have $|\dot{x}(t)| \leqslant \alpha(t)$, for a.a. $t \in J$, and

$$\big|x(t_1) - x(t_2)\big| \leqslant \left|\int_{t_1}^{t_2} \alpha(s)\, \mathrm{d}s\right|.$$

This implies an equicontinuity of all $x \in T(Q)$.

We show that the set Γ_T is closed (cf. Section 2.1).

Let $\Gamma_T \supset \{(q_k, x_k)\} \to (q, x)$. Let K be an arbitrary compact interval such that α is integrable on K. By conditions (ii) and (iii), the sequence $\{x_k\}$ satisfies the assumptions of Proposition 4.1.

Thus, there exists a subsequence (denoted just the same) $\{x_k\}$, uniformly convergent to x on K (because the limit is unique) and such that $\{\dot{x}_k\}$ weakly converges to $\dot{x}$ in L^1. Therefore, $\dot{x}$ belongs to the weak closure of the set $\mathrm{conv}\{\dot{x}_m \mid m \geqslant k\}$, for every $k \geqslant 1$. By the mentioned Mazur theorem, $\dot{x}$ also belongs to the strong closure of this set. Hence, for every $k \geqslant 1$, there is $z_k \in \mathrm{conv}\{\dot{x}_m \mid m \geqslant k\}$ such that $\|z_k - \dot{x}\|_{L^1} \leqslant 1/k$. This implies that there exists a subsequence $z_{k_l} \to \dot{x}$ a.e. in K.

Let $s \in K$ be such that

$$G(s, \cdot, \cdot) \text{ is u.s.c.}, \quad \lim_{l \to \infty} z_{k_l}(s) = \dot{x}(s), \quad \dot{x}_k(s) \in G\big(s, x_k(s), q_k(s)\big).$$

Let $\varepsilon > 0$. There is $\delta > 0$ such that $G(s, z, p) \subset N_\varepsilon(G(s, x(s), q(s)))$, whenever $|x(s) - z| < \delta$ and $|q(s) - p| < \delta$. But we know that there exists $N \geqslant 1$ such that $|x(s) - x_m(s)| < \delta$ and $|q(s) - q_m(s)| < \delta$, for every $m \geqslant N$. Hence,

$$\dot{x}_k(s) \in G\big(s, x_k(s), q_k(s)\big) \subset N_\varepsilon\big(G\big(s, x(s), q(s)\big)\big).$$

By the convexity of $G(s, x(s), q(s))$, for $k_l \geqslant N$, we have

$$z_{k_l}(s) \in N_\varepsilon\big(G\big(s, x(s), q(s)\big)\big).$$

Thus, $\dot{x}(s) \in \overline{N_\varepsilon(G(s, x(s), q(s)))}$, for every $\varepsilon > 0$. This implies

$$\dot{x}(s) \in G\big(s, x(s), q(s)\big).$$

Since K was arbitrary, $\dot{x}(t) \in G(t, x(t), q(t))$, a.e. in J. □

We can now state one of the main results of this subsection.

THEOREM 4.1. *Consider the boundary value problem*

$$\begin{cases} \dot{x}(t) \in F\big(t, x(t)\big), & \text{for a.a. } t \in J, \\ x \in S, \end{cases} \tag{4.3}$$

where J is a given real interval, $F : J \times \mathbb{R}^n \multimap \mathbb{R}^n$ is a u-Carathéodory map and S is a subset of $\mathrm{AC}_{\mathrm{loc}}(J, \mathbb{R}^n)$.

Let $G : J \times \mathbb{R}^n \times \mathbb{R}^n \times [0, 1] \multimap \mathbb{R}^n$ be a u-Carathéodory map (*cf. Definition* 2.10) *such that*

$$G(t, c, c, 1) \subset F(t, c), \quad \text{for all } (t, c) \in J \times \mathbb{R}^n.$$

Assume that

(i) *there exist a retract Q of $C(J, \mathbb{R}^n)$ and a closed bounded subset S_1 of S such that the associated problem*

$$\begin{cases} \dot{x}(t) \in G\big(t, x(t), q(t), \lambda\big), & \text{for a.a. } t \in J, \\ x \in S_1 \end{cases} \tag{4.4}$$

is solvable with an R_δ-set of solutions, for each $(q, \lambda) \in Q \times [0, 1]$,

(ii) *there exists a locally integrable function $\alpha : J \to \mathbb{R}$ such that*

$$\big|G\big(t, x(t), q(t), \lambda\big)\big| \leqslant \alpha(t), \quad \text{a.e. in } J,$$

for any $(q, \lambda, x) \in \Gamma_T$, where T denotes the set-valued map which assigns to any $(q, \lambda) \in Q \times [0, 1]$ the set of solutions of (4.4),

(iii) $T(Q \times \{0\}) \subset Q$,

(iv) *if* $Q \ni q_j \to q \in Q$, $q \in T(q,\lambda)$, *then there exists* $j_0 \in \mathbb{N}$ *such that, for every* $j \geqslant j_0$, $\theta \in [0,1]$ *and* $x \in T(q_j,\theta)$, *we have* $x \in Q$.

Then problem (4.3) *has a solution.*

PROOF. Consider the set

$$Q' = \{ y \in C(J,\mathbb{R}^{n+1}) \mid y(t) = (q(t),\lambda),\ q \in Q,\ \lambda \in [0,1] \}.$$

By Proposition 4.2, we obtain that the set-valued map $T : Q \times [0,1] \multimap S_1$ is u.s.c., and so it belongs to the class $J(Q \times [0,1], C(J,\mathbb{R}^n))$. Moreover, it has a relatively compact image. Assumption (iv) implies that T is a homotopy in $J_A(Q, C(J,\mathbb{R}^n))$. Corollary 3.1 in Section 3 now gives the existence of a fixed point of $T(\cdot,1)$. However, by the hypothesis, it is a solution of (4.3). ☐

Note that the conditions (iii) and (iv) in the above theorem hold if $S_1 \subset Q$.

COROLLARY 4.1. *Consider the boundary value problem* (4.3).
Let $G : J \times \mathbb{R}^n \times \mathbb{R}^n \multimap \mathbb{R}^n$ *be a u-Carathéodory map such that*

$$G(t,c,c) \subset F(t,c), \quad \textit{for all } (t,c) \in J \times \mathbb{R}^n.$$

Assume that

(i) *there exists a retract* Q *of* $C(J,\mathbb{R}^n)$ *such that the associated problem*

$$\begin{cases} \dot{x}(t) \in G(t,x(t),q(t)), & \textit{for a.a. } t \in J, \\ x \in S \cap Q \end{cases} \tag{4.5}$$

has an R_δ*-set of solutions, for each* $q \in Q$,

(ii) *there exists a locally integrable function* $\alpha : J \to \mathbb{R}$ *such that*

$$|G(t,x(t),q(t))| \leqslant \alpha(t), \quad \textit{a.e. in } J,$$

for any $(q,x) \in \Gamma_T$,

(iii) $T(Q)$ *is bounded in* $C(J,\mathbb{R}^n)$ *and* $\overline{T(Q)} \subset S$.

Then problem (4.3) *has a solution.*

Making use of the special case of Theorem 3.3 and modifying appropriately the proof of Theorem 4.1, we can easily obtain the following:

COROLLARY 4.2. *Consider problem* (4.3) *and assume that all the assumptions of Corollary* 4.1 *hold with the convex closed set* Q *and nonempty acyclic sets of solutions* (4.5). *Then the problem* (4.3) *has a solution.*

Let us note that in applications solution sets are, in fact, R_δ-sets.

If, in particular, $J = [a,b]$ (i.e. compact), then Theorem 4.1 can be easily reformulated (see Remark 3.7) as follows.

COROLLARY 4.3. *Consider the boundary value problem* (4.3), *where* $J = [a, b]$ *is a compact interval,* $F : J \times \mathbb{R}^n \multimap \mathbb{R}^n$ *is a u-Carathéodory map and* $S \subset \mathrm{AC}(J, \mathbb{R}^n)$.

Let $G : J \times \mathbb{R}^n \times \mathbb{R}^n \times [0, 1] \multimap \mathbb{R}^n$ *be a u-Carathéodory map such that* $G(t, c, c, 1) \subset F(t, c)$, *for all* $(t, c) \in J \times \mathbb{R}^n$. *Assume that*

(i) *there exist a* (*bounded*) *retract* Q *of* $C(J, \mathbb{R}^n)$ *such that* $Q \setminus \partial Q$ *is nonempty* (*open*) *and a closed bounded subset* S_1 *of* S *such that the associated problem* (4.4) *is solvable with an* R_δ*-set of solutions, for each* $(q, \lambda) \in Q \times [0, 1]$, *and conditions* (ii) *and* (iii) *in Theorem* 4.1 *hold true,*

(ii) *the solution map* T (*defined in condition* (ii) *of Theorem* 4.1) *has no fixed points on the boundary* ∂Q *of* Q, *for every* $(q, \lambda) \in Q \times [0, 1]$.

Then problem (4.3) *has a solution.*

REMARK 4.1. In the (single-valued) case of Carathéodory ODEs, we can only assume in Theorem 4.1(i), Corollary 4.1(i), Corollary 4.2 and Corollary 4.3(i) that the related linearized problems are uniquely solvable.

Since $C^{(n-1)}(J)$ can be considered as a subspace of $C(J, \mathbb{R}^n)$, we can also apply the previous results to nth-order scalar differential equations and inclusions. To solve an existence problem, one should check suitable a priori bounds for all the derivatives up to the order $n - 1$. Our technique simplifies a work. Let us describe it below.

We need the following lemma [52, Lemma 2.1] related to the Banach space $H^{n,1}(I)$:[2]

LEMMA 4.1. *Let* I *be a compact real interval and let* $a_0, a_1, \dots, a_{n-1} : I \times \mathbb{R}^n \to \mathbb{R}$ *be u-Carathéodory functions. Given any* $q \in C^{(n-1)}(I)$, *consider the following linear* n*th-order differential operator* $L_q : H^{n,1}(I) \to L^1(I)$:

$$L_q(x)(t) = x^{(n)}(t) + \sum_{i=0}^{n-1} a_i\bigl(t, q(t), \dots, q^{(n-1)}(t)\bigr)x^{(i)}(t).$$

Assume there exists a subset Q *of* $C^{(n-1)}(I)$ *and an* L^1*-function* $\beta : I \to \mathbb{R}$ *such that, for any* $q \in Q$ *and any* $i = 0, 1, \dots, n - 1$, *we have*

$$\bigl|a_i\bigl(t, q(t), \dots, q^{(n-1)}(t)\bigr)\bigr| \leqslant \beta(t), \quad \text{a.e. in } I.$$

Then the following two norms are equivalent in $H^{n,1}(I)$:

$$\|x\| = \sum_{i=0}^{n-1} \sup_{t\in I}\bigl|x^{(i)}(t)\bigr| + \int_I \bigl|x^{(n)}(t)\bigr|\,\mathrm{d}t,$$

$$\|x\|_Q = \sup_{t\in I}\bigl|x(t)\bigr| + \sup_{q\in Q} \int_I \bigl|L_q(x)(t)\bigr|\,\mathrm{d}t.$$

---

[2] By $H^{n,1}(I)$, we denote the Banach space of all $C^{(n-1)}$-functions $x : I \to \mathbb{R}$, where I is a compact interval, with absolutely continuous $(n - 1)$th derivatives.

COROLLARY 4.4. *Consider the scalar problem*

$$\begin{cases} x^{(n)}(t) \in \displaystyle\sum_{i=0}^{n-1} a_i\big(t, x(t), \ldots, x^{(n-1)}(t)\big)x^{(i)}(t) \\ \qquad\qquad + F\big(t, x(t), \ldots, x^{(n-1)}(t)\big), \quad \text{for a.a. } t \in J, \\ x \in S, \end{cases} \tag{4.6}$$

where $J \subset \mathbb{R}$, $S \subset C(J)$ and a_i, F are u-Carathéodory maps on $J \times \mathbb{R}^n$.

Suppose that there exists a u-Carathéodory map $G : J \times \mathbb{R}^n \times \mathbb{R}^n \times [0,1] \multimap \mathbb{R}^n$ such that, for every $c \in \mathbb{R}^n$ and $\lambda \in [0,1]$, $G(t, c, c, 1) \subset F(t, c)$, a.e. in J. Then problem (4.6) *has a solution, provided the following conditions are satisfied*:

(i) *there is a retract Q of the space $C^{(n-1)}(J)$ such that, for every $(q, \lambda) \in Q \times [0,1]$, the following problem,*

$$\begin{cases} x^{(n)}(t) \in \displaystyle\sum_{i=0}^{n-1} a_i\big(t, q(t), \ldots, q^{(n-1)}(t)\big)x^{(i)}(t) \\ \qquad\qquad + G\big(t, x(t), \ldots, x^{(n-1)}(t), q(t), \ldots, q^{(n-1)}(t), \lambda\big), \quad \text{for a.a. } t \in J, \\ x \in S \cap Q, \end{cases} \tag{4.7}$$

has an R_δ-set of solutions,

(ii) *there is a locally integrable function $\alpha : J \to \mathbb{R}$ such that, for every $i = 0, \ldots, n-1$:*

$$\big|a_i\big(t, q(t), \ldots, q^{(n-1)}(t)\big)\big| \leqslant \alpha(t), \quad \text{a.e. in } J,$$

and

$$\big|G\big(t, x(t), \ldots, x^{(n-1)}(t), q(t), \ldots, q^{(n-1)}(t), \lambda\big)\big| \leqslant \alpha(t), \quad \text{for a.e. } t \in J,$$

for each $(q, \lambda, x) \in Q \times [0,1] \times C^{(n-1)}(J)$ satisfying (4.7),

(iii) *$T(Q \times \{0\}) \subset Q$, where T denotes the set-valued map which assigns to any $(q, \lambda) \in Q \times [0,1]$ the set of solutions of* (4.7),

(iv) *the set $T(Q \times [0,1])$ is bounded in $C(J)$ and its $C^{(n-1)}$-closure is contained in S (in particular, this holds if $S \cap C^{(n-1)}(J)$ is closed in $C^{(n-1)}(J)$),*

(v) *if $\{q_j\} \subset Q$ converges to $q \in Q$, $q \in T(q, \lambda)$ in $C^{(n-1)}(J)$, then there exists $j_0 \in \mathbb{N}$ such that, for every $j \geqslant j_0$, $\theta \in [0,1]$ and $x \in T(q_j, \theta)$, we have $x \in Q$.*

PROOF. We construct a new problem in the following way:

Define $\widetilde{F} : J \times \mathbb{R}^n \multimap \mathbb{R}^n$,

$$\widetilde{F}\big(t, x(t), \ldots, x^{(n-1)}(t)\big) = F\big(t, x(t), \ldots, x^{(n-1)}(t)\big) + \sum_{i=0}^{n-1} a_i\big(t, x(t), \ldots, x^{(n-1)}(t)\big)x^{(i)}(t).$$

Denote $\overline{x}(t) = (x(t), \dots, x^{(n-1)}(t)) \in \mathbb{R}^n$ and define $F' : J \times \mathbb{R}^n \multimap \mathbb{R}^n$,

$$F'\big(t, \overline{x}(t)\big) = \big\{\big(\dot{x}(t), \dots, x^{(n-1)}(t), y\big) \mid y \in \widetilde{F}\big(t, x(t), \dots, x^{(n-1)}(t)\big)\big\}.$$

So, we have a problem

$$\begin{cases} \dot{\overline{x}}(t) \in F'\big(t, \overline{x}(t)\big), & \text{for a.a. } t \in J, \\ \overline{x} \in \overline{S}, \end{cases} \tag{4.8}$$

where $\overline{S}$ is an image of $S \cap C^{(n-1)}(J)$ via the inclusion $i : C^{(n-1)}(J) \to C(J, \mathbb{R}^n)$.

Analogously, we find the associated problem

$$\begin{cases} \dot{\overline{x}}(t) \in G'\big(t, \overline{x}(t), \overline{q}(t), \lambda\big), & \text{for a.a. } t \in J, \\ \overline{x} \in \overline{S} \cap \overline{Q}. \end{cases} \tag{4.9}$$

Notice that

(1) $G'(t, \overline{x}(t), \overline{q}(t), 1) \subset F'(t, \overline{x}(t))$,
(2) the set $\overline{Q} = i(Q)$ is a retract of $C(J, \mathbb{R}^n)$,
(3) $\overline{S} \subset \mathrm{AC}_{\mathrm{loc}}(J, \mathbb{R}^n)$,
(4) for every $(q, \lambda) \in Q \times [0, 1]$, the sets of solutions of the problems (4.7) and (4.9) are the same,
(5) $\overline{T}(\overline{Q} \times [0, 1]) \subset \overline{S}$, where $\overline{T}$ is a suitable map corresponding to T

and

$$\begin{aligned} \big|G'\big(t, \overline{x}(t), \overline{q}(t), \lambda\big)\big| &\leqslant \big|G\big(t, x(t), \dots, x^{(n-1)}, q(t), \dots, q^{(n-1)}(t), \lambda\big)\big| \\ &\quad + \sum_{i=0}^{n-1} \big|a_i\big(t, q(t), \dots, q^{(n-1)}(t)\big)\big| \big|x^{(i)}(t)\big| \\ &\leqslant \alpha(t) + \alpha(t) \sum_{i=0}^{n-1} \big|x^{(i)}(t)\big|. \end{aligned}$$

Since $T(Q \times [0, 1])$ is bounded in $C(J)$, there exists a positive continuous function $m : J \to \mathbb{R}$ such that $|x(t)| \leqslant m(t)$, for all $t \in J$ and any $x \in T(Q \times [0, 1])$. We will show that $T(Q \times [0, 1])$ is also bounded in $C^{(n-1)}(J)$. It is sufficient to prove that, for any compact subinterval I in J, there is a constant $M > 0$ such that

$$p_I(x) = \sum_{i=0}^{n-1} \sup \big|x^{(i)}(t)\big| \leqslant M, \quad \text{for all } x \in T\big(Q \times [0, 1]\big).$$

Let $I \subset J$ be an arbitrary compact interval. Using the notation in Lemma 4.1, we see that $p_I(x) \leqslant \|x\|$ and, by the equivalence of norms,

$$\|x\| \leqslant c\|x\|_Q \leqslant c\left(\max_{t \in I} m(f) + \int_I \alpha(t)\, \mathrm{d}t\right) \leqslant M.$$

We conclude that $T(Q \times [0,1])$ is bounded in $C^{(n-1)}(J)$ which implies that $\overline{T}(\overline{Q} \times [0,1])$ is bounded in $C(J, \mathbb{R}^n)$. Moreover, there exists a continuous function $\varphi : J \to \mathbb{R}$ such that

$$\left|G'\left(t, \overline{x}(t), \overline{q}(t), \lambda\right)\right| \leqslant \alpha(t)\left(1 + \varphi(t)\right).$$

Obviously, the right-hand side of the above inequality is a locally integrable function.

Finally, an easy computation shows that the condition (iv) in Theorem 4.1 holds for $\overline{Q}$ and $\overline{T}$. By Theorem 4.1, there exists a solution of (4.8) as well as the one of (4.6). □

The same argument as in Corollary 4.1 shows how to modify Corollary 4.4 for the following scalar problem, namely

$$\begin{cases} x^{(n)}(t) \in \displaystyle\sum_{i=0}^{n-1} a_i\left(t, x(t), \dots, x^{(n-1)}(t)\right)x^{(i)}(t) \\ \qquad\qquad + F\left(t, x(t), \dots, x^{(n-1)}(t)\right), \quad \text{for a.a. } t \in J, \\ x \in S, \end{cases} \tag{4.10}$$

where $J \subset \mathbb{R}$, $S \subset C(J)$ and a_i, F are u-Carathéodory maps on $J \times \mathbb{R}^n$, by means of the following linearized problem

$$\begin{cases} x^{(n)}(t) \in \displaystyle\sum_{i=0}^{n-1} a_i\left(t, q(t), \dots, q^{(n-1)}(t)\right)x^{(i)}(t) \\ \qquad\qquad + G\left(t, x(t), \dots, x^{(n-1)}(t), q(t), \dots, q^{(n-1)}(t)\right), \quad \text{for a.a. } t \in J, \\ x \in S \cap Q, \end{cases} \tag{4.11}$$

where Q is a retract of the space $C^{(n-1)}(J)$.

Theorem 3.9 in Section 3.3 gives similar consequences as those of Theorem 3.8 in Section 3.3. Unfortunately, the weakness of the assumption on solutions causes that we have to assume the convexity of the set Q. In spite of it, the results given below are important because of the applications.

THEOREM 4.2. *Consider the boundary value problem* (4.3), *where J is a given real interval, $F : J \times \mathbb{R}^n \multimap \mathbb{R}^n$ is a u-Carathéodory map and S is a subset of* $\mathrm{AC}_{\mathrm{loc}}(J, \mathbb{R}^n)$.

Let $G : J \times \mathbb{R}^n \times \mathbb{R}^n \times [0,1] \multimap \mathbb{R}^n$ be as in Theorem 4.1. *Assume that the assumptions* (i)–(iii) *of Theorem* 4.1 *hold, with the convexity of the set Q, and*

(iv) *if $\partial Q \times [0,1] \supset \{(q_j, \lambda_j)\}$ converges to $(q, \lambda) \in \partial Q \times [0,1]$, $q \in T(q, \lambda)$, then there exists $j_0 \in \mathbb{N}$ such that, for every $j \geqslant j_0$, and $x_j \in T(q_j, \lambda_j)$, we have $x_j \in Q$.*

Then problem (4.3) *has a solution.*

The proof can be obtained immediately by using our continuation principle presented in Theorem 3.9 in Section 3.3.

REMARK 4.2. In the (single-valued) case of Carathéodory ODEs, we can again only assume in Corollary 4.4(i) and Theorem 4.2 that the linearized problems are uniquely solvable. If the associated problem (4.4) for G is so uniquely solvable, for every $(q, \lambda) \in Q \times [0, 1]$, then, by continuity of T, we can reformulate the above condi tion (iv) as follows:

(iv′) if $\{(x_j, \lambda_j)\}$ is a sequence in $S_1 \times [0, 1]$, with $\lambda_j \to \lambda \in [0, 1)$ and x_j is converging to a solution $x \in Q$ of (4.4) (corresponding to (x, λ)), then x_j belongs to Q, for j sufficiently large.

Now, we are interested in the existence of several solutions of problem (4.3). For this, the Nielsen theory developed in Section 3.2 will be applied. It will be convenient to use the following definition.

DEFINITION 4.1. We say that the mapping $T : Q \multimap U$ is *retractible onto* Q, where U is an open subset of $C(J, \mathbb{R}^n)$ containing Q, if there is a (continuous) retraction $r : U \to Q$ and $p \in U \setminus Q$ with $r(p) = q$ implies that $p \notin T(q)$.

Its advantage consists in the fact that, for a retractible mapping $T : Q \multimap U$ onto Q with a retraction r in the sense of Definition 4.1, its composition with r, $r|_{T(Q)} \circ T : Q \multimap Q$, has a fixed point $\widehat{q} \in Q$ if and only if $\widehat{q}$ is a fixed point of T.

The following principal statement characterizes the matter.

THEOREM 4.3. *Let* $G : J \times \mathbb{R}^n \times \mathbb{R}^n \multimap \mathbb{R}^n$ *be u-Carathéodory map* (*cf. Definition* 2.10) *and assume that*

(i) *there exists a closed, connected subset* Q *of* $C(J, \mathbb{R}^n)$ *with a finitely generated abelian fundamental group such that, for any* $q \in Q$, *the set* $T(q)$ *of all solutions of the linearized problem* (4.2) *is* R_δ,

(ii) $T(Q)$ *is bounded in* $C(J, \mathbb{R}^n)$ *and* $\overline{T(Q)} \subset S$,

(iii) *there exists a locally integrable function* $\alpha : J \to \mathbb{R}$ *such that*

$$\bigl|G\bigl(t, x(t), q(t)\bigr)\bigr| := \sup\bigl\{|y| \mid y \in G\bigl(t, x(t), q(t)\bigr)\bigr\} \leqslant \alpha(t), \quad \textit{a.e. in } J,$$

for any pair $(q, x) \in \Gamma_T$, *where* Γ_T *denotes the graph of* T.

Assume, furthermore, that

(iv) *the operator* $T : Q \multimap U$, *related to* (4.2), *is retractible onto* Q *with a retraction* r *in the sense of Definition* 4.1.

At last, let

$$G(t, c, c) \subset F(t, c) \tag{4.12}$$

for a.a. $t \in J$ *and any* $c \in \mathbb{R}^n$. *Then the original problem* (4.3) *admits at least* $N(r|_{T(Q)} \circ T)$ *solutions belonging to* Q, *where* N *stands for the Nielsen number defined in Definition* 3.2 *in Section* 3.2.

PROOF. By the hypothesis, Q is a connected (metric) ANR-space with a finitely generated abelian fundamental group and $T(q)$ is an R_δ-mapping. Since T is also, according to

Proposition 4.2, u.s.c. and such that $\overline{T(Q)}$ is compact, $r \circ T$ is compact and admissible. This follows from the commutativity of the following diagram:

$$\begin{tikzcd}
Q \arrow[r, "T"] & U \arrow[r, "r"] & Q \\
& \Gamma_T \arrow[ul, Rightarrow, "p_T"'] \arrow[u, "q_T"'] \arrow[ur, "r\circ q_T"'] &
\end{tikzcd}$$

where (p_T, q_T) is a pair of natural projections of the graph Γ_T and p_T is Vietoris. Therefore, according to Theorem 3.4 in Section 3.2, $(p_T, r|_{T(Q)} \circ q_T)$ admits at least $N(r|_{T(Q)} \circ T(\cdot))$ coincidence points. Because of Definition 4.1, they represent the solutions of problem (4.2) and, in view of (4.12), they also satisfy the original problem (4.3). $\square$

REMARK 4.3. In the (single-valued) case of Carathéodory ODEs, we can only assume in Theorem 4.3(i) that the linearized problem (4.2) is uniquely solvable. Moreover, the requirement that the fundamental group $\pi(Q)$ of Q to be finitely generated and abelian can be then omitted (see Section 3.2).

Furthermore, we will consider boundary value problems on arbitrary (possibly infinite) intervals for differential inclusions in Banach spaces. We start with some definitions.

Let E be a Banach space with the norm $\|\cdot\|$. Denote by $C(J, E)$ the space of all continuous functions $x : J \to E$ with the locally convex topology generated by the uniform convergence on compact subintervals of J (possibly, the whole $\mathbb{R}$). This topology is completely metrizable, and thus $C(J, E)$ is a Fréchet space.

Recall that a mapping $x : J \to E$ is locally absolutely continuous if x is absolutely continuous on every compact subinterval of J. Unfortunately, in general, on each interval $[a, b] \subset J$, there need not exist $\dot{x}(t)$ (in the sense of Fréchet), for almost all (a.a.) $t \in [a, b]$ with $\dot{x} \in L^1([a, b], E)$ (the set of all Bochner integrable functions $[a, b] \to E$) and so need not be

$$x(t) = x_0 + \int_a^t \dot{x}(s)\,\mathrm{d}s.$$

It is so if E satisfies the Radon–Nikodym property, in particular, if E is reflexive. Moreover, we have the following result (cf. [48]).

LEMMA 4.2. *Suppose $x : [a, b] \to E$ is absolutely continuous, $\dot{x}$ exists a.e., and*

$$\big\|\dot{x}(t)\big\| \leqslant y(t), \quad \textit{a.e., for some } y \in L^1\big([a, b], \mathbb{R}\big).$$

Then $\dot{x} \in L^1([a, b], E)$ and

$$\int_\tau^t \dot{x}(s)\,\mathrm{d}s = x(t) - x(\tau) \quad \big(t, \tau \in [a, b]\big). \tag{4.13}$$

The set of all locally absolutely continuous functions from J to E, satisfying all the above properties, will be denoted by $\mathrm{AC}_{\mathrm{loc}}(J, E)$.

Consider now the differential inclusion

$$\dot{x} \in F(t, x), \tag{4.14}$$

where $F : J \times E \multimap E$ is a u-Carathéodory map, i.e.

(C1) $F(t, x)$ is nonempty, compact and convex, for every $(t, x) \in J \times E$,

(C2) $F(t, \cdot)$ is u.s.c., for a.a. $t \in J$,

(C3) $F(\cdot, x)$ is strongly measurable (cf. Definition 2.9), on every compact interval $[a, b]$, for each $x \in E$.

By a *solution* of this differential inclusion we mean again a map $x \in \mathrm{AC}_{\mathrm{loc}}(J, E)$ satisfying (4.14), for a.a. $t \in J$.

To a u-Carathéodory map F, we associate the Nemytskiĭ (or superposition) operator $N_F : C(J, E) \multimap L^1_{\mathrm{loc}}(J, E)$ given by

$$N_F(x) := \left\{ f \in L^1_{\mathrm{loc}}(J, E) \mid f(t) \in F\big(t, x(t)\big), \text{ a.e. on } J \right\},$$

for each $x \in C(J, E)$.

In the sequel, we will need the following lemma (see [100, p. 88] and cf. Remark 2.1).

LEMMA 4.3. *Let $[a, b]$ be a compact interval. Let $F : [a, b] \times E \multimap E$ be a u-Carathéodory mapping and assume in addition that, for every nonempty bounded set $\Omega \subset E$, there exists $\nu = \nu(\Omega) \in L^1([a, b])$ such that*

$$\big\| F(t, x) \big\| := \sup\big\{ \|z\| \mid z \in F(t, x) \big\} \leqslant \nu(t),$$

for a.e. $t \in [a, b]$ and every $x \in \Omega$. Then the Nemytskiĭ operator

$$N_F : C\big([a, b], E\big) \multimap L^1\big([a, b], E\big)$$

has nonempty, convex values. Moreover, given sequences $\{x_n\} \subset C([a, b], E)$ and $\{f_n\} \subset L^1([a, b], E)$, $f_n \in N_F(x_n)$, $n \geqslant 1$, such that $x_n \to x$ in $C([a, b], E)$ and $f_n \to f$ weakly in $L^1([a, b], E)$, then $f \in N_F(x)$.

The following lemma extends Proposition 4.1 to infinite-dimensional spaces (see again [42, Theorem 0.3.4]).

LEMMA 4.4. *Assume that a sequence $\{x_k \mid [a, b] \to E\}$ of AC-maps satisfies the following conditions*:

(i) *$\{x_k(t)\}$ is relatively compact, for each $t \in [a, b]$*,

(ii) *there exists $\alpha \in L^1([a, b])$ such that $\|\dot{x}_k(t)\| \leqslant \alpha(t)$, for a.a. $t \in [a, b]$.*

Then there exists a subsequence (*again denoted by $\{x_k\}$*) *that converges to an absolutely continuous map $x : [a, b] \to E$ in the following sense*:

(iii) *$x_k \to x$ in $C([a, b], E)$*,

(iv) $\dot{x}_k \to \dot{x}$ *weakly in* $L^1([a,b], E)$.

PROPOSITION 4.3. *Let* $G : J \times E \times E \multimap E$ *be a u-Carathéodory map and let* S *be a nonempty subset of* $\mathrm{AC}_{\mathrm{loc}}(J, E)$. *Assume that*:

(i) *there exists a closed* $Q \subset C(J, E)$ *such that, for any* $q \in Q$, *the boundary value problem*

$$\begin{cases} \dot{x}(t) \in G\big(t, x(t), q(t)\big), & \text{for a.a. } t \in J, \\ x \in S, \end{cases}$$

has a solution. Denote by $T : Q \multimap S$ *the solution mapping.*

(ii) *There exist* $\alpha, \beta, \gamma \in L^1_{\mathrm{loc}}(J)$ *such that*

$$\big\|G(t, x, y)\big\| \leqslant \alpha(t) + \beta(t)\|x\| + \gamma(t)\|y\|,$$

for a.a. $t \in J$ *and every* $(x, y) \in E^2$.

(iii) *If* $\{(q_n, x_n)\}$ *is a sequence in the graph of* T *and* $(q_n, x_n) \to (q, x)$, *then* $x \in S$.

Then $T : Q \multimap S$ *has a closed graph* (S *is endowed with the topology of* $C(J, E)$).

PROOF. Let $\{(q_n, x_n)\}$ be an arbitrary sequence in the graph of T, i.e. $x_n \in T(q_n)$, for every $n \in \mathbb{N}$, and assume that $(q_n, x_n) \to (q_0, x_0)$. Thus, we see that

$$\dot{x}_n(t) \in G\big(t, x_n(t), q_n(t)\big), \quad \text{for a.a. } t \in J,$$

and $x_n \in S$. Then $q_0 \in Q$ and, by assumption (iii), $x_0 \in S$.

Now, let $[a, b]$ be an interval in J. Using assumption (ii), we see that the sequence $\{x_n\}$ satisfies the assumptions of Lemma 4.4. Thus, $\{x_n\}$ converges uniformly on $[a, b]$ to x_0 (because this limit is unique) and $\{\dot{x}_n\}$ converges to $\dot{x}_0$, weakly in $L^1([a, b], E)$. Using Lemma 4.3, it follows that $\dot{x}_0(t) \in G(t, x_0(t), q_0(t))$, for a.a. $t \in [a, b]$. Since $[a, b]$ was arbitrary, we see that indeed $\dot{x}_0(t) \in G(t, x_0(t), q_0(t))$, for a.a. $t \in J$ and $x_0 \in T(q_0)$. □

As another of the main results of this subsection, we can formulate the following continuation principle.

THEOREM 4.4. *Consider the boundary value problem* (*e.g., in a reflexive Banach space* E; *cf. Lemma* 4.2):

$$\begin{cases} \dot{x}(t) \in F\big(t, x(t)\big), & \text{for a.a. } t \in J, \\ x \in S, \end{cases} \tag{4.15}$$

where $F : J \times E \multimap E$ *is a u-Carathéodory map and* S *is a subset of* $\mathrm{AC}_{\mathrm{loc}}(J, E)$. *Let* $G : J \times E \times E \times [0, 1] \multimap E$ *be a u-Carathéodory map* (*cf. Definition* 2.10) *such that*

$$G(t, c, c, 1) \subset F(t, c), \quad \text{for all } (t, c) \in J \times E. \tag{4.16}$$

Assume that:

(i) *there exists a closed, convex* $Q \subset C(J, E)$ *and a closed subset* S_1 *of* S *such that the problem*

$$\begin{cases} \dot{x}(t) \in G\big(t, x(t), q(t), \lambda\big), & \text{for a.a. } t \in J, \\ x \in S_1 \end{cases}$$

is solvable with an R_δ*-set* $T(q, \lambda)$, *for each* $(q, \lambda) \subset Q \times [0, 1]$.

(ii) *There exist* $\alpha, \beta, \gamma \in L^1_{\mathrm{loc}}(I)$ *such that*

$$\big\|G(t, x, y, \lambda)\big\| \leqslant \alpha(t) + \beta(t)\|x\| + \gamma(t)\|y\|,$$

for a.a. $t \in J$, *every* $(x, y) \in E^2$ *and every* $\lambda \in [0, 1]$.

(iii) T *is quasi-compact, i.e.* T *maps compact subsets onto compact subsets, and there exists a measure of noncompactness* μ *in the sense of Definitions* 2.7 *and* 2.8 *in Section* 2.2 *such that, for each* $\Omega \subset Q$, *if*

$$\mu\big(T\big(\Omega \times [0, 1]\big)\big) \geqslant \mu(\Omega),$$

then Ω *is relatively compact.*

(iv) $T(Q \times \{0\}) \subset Q$.

(v) *For each* $\lambda_0 \in [0, 1]$ *and* $q \in T(q_0, \lambda_0)$, *if* $q_n \to q_0$ *in* Q, *then there is* $n_0 \in \mathbb{N}$ *such that, for each* $n \geqslant n_0$, $\lambda \in [0, 1]$ *and* $x \in T(q_n, \lambda)$, *we have* $x \in Q$.

Then problem (4.15) *has a solution.*

PROOF. Using Proposition 4.3, we see that the map $T : Q \times [0, 1] \multimap S_1$ has a closed graph. Since T is also quasi-compact (assumption (iii)), we can easily derive that T is indeed an u.s.c. set-valued map (see, e.g., [78, Theorem 1.1.12]). From assumption (i), we get therefore that $T \in J(Q \times [0, 1], C(\mathbb{R}, E))$ and assumption (iii) implies that T is also μ-condensing. By (v), we finally see that T is a homotopy in J_A, and thus Corollary 3.4 in Section 3.3 implies the existence of a fixed point of $T(\cdot, 1)$. However, by the inclusion (4.16), it is a solution of (4.15). □

REMARK 4.4. As we can see, Theorem 4.4 extends Theorem 4.1 into the infinite-dimensional setting, when replacing $\mathbb{R}^n$ by a real Banach space. On the other hand, this is possible with some loss, namely Q is only convex and the solution operator T is assumed to be quasi-compact, additionally. Because of those restrictions, we are unfortunately unable to establish a full infinite dimensional analogy of Theorem 4.1.

If, in particular, $J = [a, b]$ (i.e. compact), then Theorem 4.4 can be simplified, in view of Remark 3.9, similarly as Corollary 4.3 w.r.t. Theorem 4.1, as follows.

COROLLARY 4.5. *Consider the problem*

$$\begin{cases} \dot{x}(t) \in F\big(t, x(t)\big), & \text{for a.a. } t \in [a, b], \\ x \in S, \end{cases} \tag{4.17}$$

where $F : [a, b] \times E \multimap E$ *is a u-Carathéodory map and* S *is a subset of absolutely continuous functions* $x : [a, b] \to E$, *all in a reflexive Banach space* E. *Let* $G : [a, b] \times E \times E \times [0, 1] \multimap E$ *be a u-Carathéodory map such that*

$$G(t, c, c, 1) \subset F(t, c), \quad \textit{for all } (t, c) \in [a, b] \times E. \tag{4.18}$$

Furthermore, assume that

(i) *there exists a convex, bounded subset* $Q \subset C([a, b], E)$ *such that* $Q \setminus \partial Q$ *is nonempty and a closed subset* S_1 *of* S *such that the problem*

$$\begin{cases} \dot{x}(t) \in G\big(t, x(t), q(t), \lambda\big), & \textit{for a.a. } t \in [a, b], \\ x \in S_1 \end{cases}$$

is solvable with R_δ*-set* $T(q, \lambda)$, *for each* $(q, \lambda) \in Q \times [0, 1]$.

(ii) *There exists* $\alpha, \beta, \gamma \in Ł^1([a, b])$ *such that*

$$\big\|G(t, x, y, \lambda)\big\| \leqslant \alpha(t) + \beta(t)\|x\| + \gamma(t)\|y\|,$$

for a.a. $t \in [a, b]$, *every* $(x, y) \in E^2$ *and every* $\lambda \in [0, 1]$.

(iii) T *is quasi-compact, i.e.* T *maps compact subsets onto compact subsets, and there exists a measure of noncompactness* μ (*see Definitions* 2.7 *and* 2.8) *such that, for each* $\Omega \subset Q$, *if*

$$\mu\big(T\big(\Omega \times [0, 1]\big)\big) \geqslant \mu(\Omega),$$

then Ω *is relatively compact.*

(iv) $T(Q \times \{0\}) \subset Q$.

(v) *The map* T *has no fixed points on the boundary* ∂Q *of* Q, *for every* $(q, \lambda) \in Q \times [0, 1]$.

Then problem (4.17) *has a solution.*

PROOF. We can proceed quite analogously as in the proof of the foregoing Theorem 4.4. The only difference consists of modifying Corollary 3.4 in the sense of Remark 3.9, both in Section 3.3. □

REMARK 4.5. In the (single-valued) case of Carathéodory ODEs, we can again only assume in Theorem 4.4(i) and Corollary 4.5(i) that the linearized problems are uniquely solvable.

Sometimes it is convenient to consider the asymptotic problems sequentially. For this purpose, it can be useful to employ

PROPOSITION 4.4. *Let* $J_1 \subset J_2 \subset \cdots$ *be compact intervals such that* $J = \bigcup_{m=1}^{\infty} J_m$ *and* $t_0 \in J_1$. *Let* $F : J \times E \multimap E$ *be a u-Carathéodory mapping with nonempty, compact and convex values. Assume, furthermore, that*

(i) *There are* $\alpha, \beta \in L^1_{\mathrm{loc}}(J, \mathbb{R})$ *with*

$$\|F(t,x)\| \leqslant \alpha(t) + \beta(t)\|x\|.$$

(ii) *There is some Carathéodory mapping* $g : J \times [0,\infty) \to [0,\infty)$ (*called a Kamke function*) *such that the only nonnegative measurable solution of*

$$x(t) \leqslant \left| \int_{t_0}^{t} g\big(s, x(s)\big)\, \mathrm{d}s \right|$$

is 0 (*a.e.*), *and such that, for a.a.* $t \in J$, $\gamma(F(\{t\} \times C)) \leqslant g(t, \gamma(C))$, *for countable, bounded subsets* $C \subset E$, *where* γ *denotes the Hausdorff measure of noncompactness.*

(iii) E *has the so called retraction property in the sense of [99], e.g.,* E *is separable or reflexive.*

If $x_m \in \mathrm{AC}(J_m, E)$ *satisfies*

$$\dot{x}_m(t) \in F\big(t, x_m(t)\big), \quad \textit{for a.a. } t \in J_m,\ m \in \mathbb{N},$$

and $\{x_m(t_0) \mid m \in \mathbb{N}\}$ *is a relatively compact set, then there is a solution* $x \in \mathrm{AC}_{\mathrm{loc}}(J, E)$ *of the inclusion* $\dot{x}(t) \in F(t, x(t))$, *for a.a.* $t \in J$, *such that, for some subsequence,*

$$x_{m_k} \to x, \quad \textit{uniformly on each } J_m,$$

and

$$\dot{x}_{m_k} \to \dot{x}, \quad \textit{weakly in } L^1(J, E).$$

If still

(iv) $\sup\{\|x_m(t)\| \mid m \in \mathbb{N},\ t \in J_m\} < \infty$

and the values of x_m, $m \in \mathbb{N}$, *are located in a closed subdomain* $\mathcal{D}$ *of* E, *then there exists an entirely bounded solution* x *on* J *with* $x(t) \in \mathcal{D}$, *for all* $t \in \mathbb{R}$.

PROOF. By (i) and the well-known Gronwall inequality (see, e.g., [72]), we get the a priori estimates

$$\|x_m(t)\| \leqslant \widetilde{x}(t) \quad \text{and} \quad \|\dot{x}_m(t)\| \leqslant \widetilde{x}(t),$$

for some $\widetilde{x} \in L^1_{\mathrm{loc}}(J, \mathbb{R})$.

We claim that $\{x_m(t) \mid m \geqslant m_t\}$ is a relatively compact set, for a.a. $t \in J$, where $m_t = \min\{m \mid t \in J_m\}$. To show it, put $h(t) := \gamma(\{x_m(t) \mid m \geqslant m_t\})$. Then h is measurable (for more details, see Proposition 11.12 in [99]). Moreover, by means of Proposition 11.12 in [99] and (ii), we obtain

$$h(t) = \gamma\big(\{x_m(t) - x_m(t_0) \mid m \geqslant m_t\}\big) = \gamma\left(\left\{ \int_{t_0}^{t} \dot{x}_m(s)\, \mathrm{d}s \;\middle|\; m \geqslant m_t \right\}\right)$$

$$\leqslant \left| \int_{t_0}^{t} \gamma\big(\{\dot{x}_m(s) \mid m \geqslant m_t\}\big)\,\mathrm{d}s \right| \leqslant \left| \int_{t_0}^{t} g\big(s, h(s)\big)\,\mathrm{d}s \right|.$$

Applying (ii) again, we arrive at $h(t) = 0$, for a.a. $t \in J$, as claimed.

Since $F(t, \cdot)$ maps compact sets into compact sets, $\{\dot{x}_m(t) \mid m \geqslant m_t\}$ becomes relatively compact as well, for a.a. $t \in J$. An application of the standard diagonalization argument implies, jointly with Lemma 4.4, the existence of a subsequence such that $x_{m_k} \to x$, uniformly on each J_m, and $\dot{x}_{m_k} \to \dot{x}$, weakly in $L^1(J, E)$, where $x \in \mathrm{AC}_{\mathrm{loc}}(J, E)$.

It follows from Lemma 4.3 that $\dot{x}(t) \in F(t, x(t))$. Since the remaining part of the assertion is implied by the foregoing one (just proved) and (iv), the proof is completed. □

REMARK 4.6. Let E be a Banach space and assume that $F : \mathbb{R} \times E \multimap E$ is a u-Carathéodory mapping (cf. Definition 2.10) such that

$$\mu\big(F(t, B)\big) \leqslant k(t)\mu(B), \quad \text{for bounded subsets } B \subset E,\ t \in \mathbb{R},$$

where $k \in L^1_{\mathrm{loc}}(\mathbb{R})$ and μ denotes either the Kuratowski MNC α or the Hausdorff MNC γ. Then it is well known (see, e.g., [58, Theorem 9.2 and Remark 9.5.4 in Chapter 4.9.3]) that the initial value problem

$$\begin{cases} \dot{x}(t) \in F\big(t, x(t)\big), & \text{for a.a. } t \in [-m, m],\ m \in \mathbb{N}, \\ x(0) = x_0, \end{cases}$$

admits a solution $x_m \in \mathrm{AC}([-m, m])$, for each $m \in \mathbb{N}$, i.e. $x \in \mathrm{AC}_{\mathrm{loc}}(\mathbb{R}, E)$. If, in particular, the values of x_m, $m \in \mathbb{N}$, are located in a given bounded, closed subdomain $\mathcal{D}$ of E, then there exists an entirely bounded solution $x \in \mathrm{AC}_{\mathrm{loc}}(\mathbb{R}, E)$ on $\mathbb{R}$, $x(0) = x_0$, with values in $\mathcal{D}$, provided E is separable or reflexive. It is namely enough to apply Proposition 4.4, for $t_0 = 0$ and $g(t, x) := 2k(t)x$. Such special g is a Kamke function by means of the Gronwall inequality.

If in particular, $E = \mathbb{R}^n$, then (ii) and (iii) hold automatically. Hence, Proposition 4.4 can be then simplified as follows.

PROPOSITION 4.5. *Let $F : \mathbb{R} \times \mathbb{R}^n \multimap \mathbb{R}^n$ be a u-Carathéodory mapping with nonempty, compact and convex values, satisfying* (i) *in Proposition* 4.4, *for $J = (-\infty, \infty)$. Then, for every $x_0 \in \mathbb{R}^n$, there exists a solution $x \in \mathrm{AC}_{\mathrm{loc}}(\mathbb{R}, \mathbb{R}^n)$ of the Cauchy problem*

$$\begin{cases} \dot{x}(t) \in F\big(t, x(t)\big), & \textit{for a.a. } t \in (-\infty, \infty), \\ x(0) = x_0. \end{cases}$$

Let $\{x_m(t)\}$ be a sequence of absolutely continuous functions such that

(i) *For every $m \in \mathbb{N}$, $x_m \in \mathrm{AC}([-m, m], \mathbb{R}^n)$ is a solution of*

$$\dot{x}(t) \in F\big(t, x(t)\big), \quad \textit{for a.a. } t \in [-m, m],$$

(ii) $\sup\{|x_m(t)| \mid m \in \mathbb{N},\ t \in [-m,m]\} := M < \infty$ *and* $x_m(t) \in \mathcal{D} \subset \mathbb{R}^n$, *for every* $t \in [-m,m]$.

Then there exists an entirely bounded solution $x \in \mathrm{AC}_{\mathrm{loc}}(\mathbb{R},\mathbb{R}^n)$ *of the inclusion*

$$\dot{x}(t) \in F\bigl(t, x(t)\bigr), \quad \text{for a.a. } t \in (-\infty,\infty),$$

such that

$$\sup_{t\in\mathbb{R}} \bigl|x(t)\bigr| \leqslant M \ (<\infty) \quad \text{and} \quad x(t) \in \mathcal{D}, \quad \text{for all } t \in \mathbb{R}.$$

4.2. *Topological structure of solution sets*

In this part, various methods for investigating the topological structure of solution sets, required in statements of the foregoing subsection, will be presented. Both initial and boundary value problems will be considered.

The classical result, due to F.S. De Blasi and J. Myjak in [57], deals with Cauchy problems for the u-Carathéodory differential inclusions in Euclidean spaces:

$$\begin{cases} \dot{x} \in F(t,x), \\ x(0) = x_0, \end{cases} \tag{4.19}$$

where $F : J \times \mathbb{R}^n \multimap \mathbb{R}^n$ is a u-Carathéodory mapping, i.e. a multivalued mapping, satisfying conditions from the beginning of Section 4.1 (cf. Definition 2.10), and such that

$$\bigl|F(t,x)\bigr| \leqslant \alpha + \beta|x|, \quad \text{for all } t \in J,\ x \in \mathbb{R}^n,$$

where α, β are nonnegative constants.

THEOREM 4.5. *Problem* (4.19), *where J is a compact interval*, *has under the above assumptions an R_δ-set of solutions.*

We omit the proof of this theorem, because below we will prove its generalized version (cf. Theorem 4.9).

We recall that a multivalued mapping $F : J \times \mathbb{R} \multimap \mathbb{R}^n$ is said to be *integrably bounded* (resp. *locally integrably bounded*) if there exists an integrable (resp. locally integrable) function $\mu : J \to [0,\infty)$ such that $|y| \leqslant \mu(t)$, for every $x \in \mathbb{R}^n$, $t \in J$ and $y \in F(t,x)$. We say that F has *at most a linear growth* (resp. *a local linear growth*) if there exist integrable (resp. locally integrable) functions $\mu, \nu : J \to [0,\infty)$ such that

$$|y| \leqslant \mu(t)|x| + \nu(t),$$

for every $x \in \mathbb{R}^n$, $t \in J$ and $y \in F(t,x)$.

It is obvious that F has at most a linear growth if there exists an integrable function $\mu : J \to [0,\infty)$ such that $|y| \leqslant \mu(t)(|x|+1)$, for every $x \in \mathbb{R}^n$, $t \in J$ and $y \in F(t,x)$.

Let us also recall that a single-valued map $f : J \times \mathbb{R}^n \to \mathbb{R}^n$ is said to be *measurable-locally Lipschitz* (mLL) if, for every $x \in \mathbb{R}^n$, there exists a neighbourhood V_x of x in $\mathbb{R}^n$ and an integrable function $L_x : J \to [0, \infty)$ such that

$$\left|f(t, x_1) - f(t, x_2)\right| \leqslant L_x(t)|x_1 - x_2|, \quad \text{for every } t \in J \text{ and } x_1, x_2 \in V_x,$$

where $f(\cdot, x)$ is measurable, for every $x \in \mathbb{R}^n$.

Now, for the considerations below, fix J as the halfline $[0, \infty)$ and assume that $F : J \times \mathbb{R}^n \multimap \mathbb{R}^n$ is again a multivalued u-Carathéodory map. Consider the Cauchy problem (4.19). By $S(F, 0, x_0)$, we denote the set of solutions of (4.19). For the characterization of the topological structure of $S(F, 0, x_0)$, it will be useful to recall the following well-known uniqueness criterion (see, e.g., [60, Theorem 1.1.2]).

THEOREM 4.6. *If f is a single-valued, integrably bounded, measurable-locally Lipschitz map, then the set $S(f, 0, x_0)$ is a singleton, for every $x_0 \in \mathbb{R}^n$.*

The following result will be employed as well.

THEOREM 4.7. *If F is locally integrably bounded, mLL-selectionable* (*i.e. if there exists a measurable-locally Lipschitz single-valued selection*), *then $S(F, 0, x_0)$ is contractible, for every $x_0 \in \mathbb{R}^n$.*

PROOF. Let $f \subset F$ be measurable-locally Lipschitz. By Theorem 4.6, the following Cauchy problem

$$\begin{cases} \dot{x} = f(t, x), \\ x(t_0) = x_0, \end{cases} \tag{4.20}$$

has exactly one solution, for every $t_0 \in J$ and $x_0 \in \mathbb{R}^n$. For the proof, it is sufficient to define a homotopy $h : S(F, 0, x_0) \times [0, 1] \to S(F, 0, x_0)$ such that

$$h(x, s) = \begin{cases} x, & \text{for } s = 1 \text{ and } x \in S(F, 0, x_0), \\ \widetilde{x}, & \text{for } s = 0, \end{cases}$$

where $\widetilde{x} = S(f, 0, x_0)$ is exactly one solution of the problem (4.20).

Define $\gamma : [0, 1) \to [0, \infty)$, $\gamma(s) = \tan(\pi s/2)$ and put

$$h(x, s)(t) = \begin{cases} x(t), & \text{for } 0 \leqslant t \leqslant \gamma(s),\ s < 1, \\ S\big(f, \gamma(s), x\big(\gamma(s)\big)\big)(t), & \text{for } \gamma(s) \leqslant t < \infty,\ s < 1, \\ x(t), & \text{for } 0 \leqslant t < \infty,\ s = 1. \end{cases}$$

Then h is a continuous homotopy, contracting $S(F, 0, x_0)$ to the point $S(f, 0, x_0)$. □

Analogously, we can get the following result.

THEOREM 4.8. *If F is locally integrably bounded, Ca-selectionable (i.e. if there exists a Carathéodory single-valued selection), or in particular c-selectionable (i.e. if there exists a continuous single-valued selection), then $S(F, 0, x_0)$ is R_δ-contractible, for every $x_0 \in \mathbb{R}^n$.*

Observe that, if $F : J \times \mathbb{R}^n \multimap \mathbb{R}^n$ is an intersection of the decreasing sequence of $F_k : J \times \mathbb{R}^n \multimap \mathbb{R}^n$, $F(t, x) = \bigcap_{k=1}^{\infty} F_k(t, x)$ and $F_{k+1}(t, x) \subset F_k(t, x)$, for almost all $t \in J$ and for all $x \in \mathbb{R}^n$, then

$$S(F, 0, x_0) = \bigcap_{k=1}^{\infty} S(F_k, 0, x_0). \tag{4.21}$$

From Theorems 4.7 and 4.8, we obtain

PROPOSITION 4.6. *Let $F : J \times \mathbb{R}^n \multimap \mathbb{R}^n$ be a multivalued map with nonempty, closed values.*

(i) *If F is σ-mLL-selectionable (i.e. it is an intersection of a decreasing sequence of mLL-selectionable mappings), then the set $S(F, 0, x_0)$ is an intersection of a decreasing sequence of contractible sets,*

(ii) *if F is σ-Ca-selectionable, i.e., it is an intersection of a decreasing sequence of Ca-selectionable mappings, then the set $S(F, 0, x_0)$ is an intersection of a decreasing sequence of R_δ-contractible sets.*

Before formulating the following important theorem, recall that, for two metric spaces X, Y and the interval J, the multivalued map $F : J \times X \multimap Y$ is *almost upper semi-continuous* (a.u.s.c.), if for every $\varepsilon > 0$ there exists a measurable set $A_\varepsilon \subset J$ such that $m(J \setminus A_\varepsilon) < \varepsilon$ and the restriction $F|_{A_\varepsilon \times X}$ is u.s.c., where m stands for the Lebesgue measure.

It is clear that every a.u.s.c. map is u-Carathéodory. In general, the reverse is not true. The following Scorza–Dragoni type result describing possible regularizations of Carathéodory maps (see, e.g., [76]) will be employed.

PROPOSITION 4.7. *Let X be a separable metric space and J be an interval. Suppose that $F : J \times X \multimap \mathbb{R}^n$ is a nonempty, compact, convex valued u-Carathéodory map. Then there exists an a.u.s.c. map $\psi : J \times X \multimap \mathbb{R}^n$ with nonempty compact convex values and such that:*

(i) *$\psi(t, x) \subset F(t, x)$, for every $(t, x) \in J \times X$,*

(ii) *if $\Delta \subset J$ is measurable, $u : \Delta \to \mathbb{R}^n$ and $v : \Delta \to X$ are measurable maps and $u(t) \in F(t, v(t))$, for almost all $t \in \Delta$, then $u(t) \in \psi(t, v(t))$, for almost all $t \in \Delta$.*

The proof of the following statement can be found in [67].

PROPOSITION 4.8. *Let E, E_1 be two separable Banach spaces, J be an interval and $F : J \times E \multimap E$ be an a.u.s.c. map with compact convex values. Then F is σ-Ca-selectionable (i.e. it is an intersection of a decreasing sequence of Ca-selectionable mappings $F_k : J \times E \multimap E_1$). The maps $F_k : J \times E \multimap E_1$ are a.u.s.c., and we have $F_k(t, e) \subset$*

$\overline{\mathrm{conv}}(\bigcup_{x\in E} F(t,x))$, for all $(t,e) \in J \times E$. Moreover, if F is integrably bounded, then F is σ-mLL-selectionable, i.e., it is an intersection of a decreasing sequence of mLL-selectionable mappings.

Now, we are ready to give

THEOREM 4.9. *If $F : J \times \mathbb{R}^n \multimap \mathbb{R}^n$ is a u-Carathéodory map with compact convex values having at most the linear growth, then $S(F,0,x_0)$ is an R_δ-set, for every $x_0 \in \mathbb{R}^n$.*

PROOF. By the hypothesis, there exists an integrable function $\mu : J \to [0,\infty)$ such that $\sup\{|y| \mid y \in F(t,x)\} \leqslant \mu(t)(|x|+1)$, for every $(t,x) \in J \times \mathbb{R}^n$. By means of the well-known Gronwall inequality (see [71]), we obtain that $|x(t)| \leqslant (|x_0| + \gamma)\exp(\gamma) = M$, where $x \in S(F,0,x_0)$ and $\gamma = \int_0^\infty \mu(s)\,\mathrm{d}s$.

Take $r > M$ and define $F : J \times \mathbb{R}^n \multimap \mathbb{R}^n$ as follows:

$$\widetilde{F}(t,x) = \begin{cases} F(t,x), & \text{if } |x| \leqslant r, \\ F\left(t, r\dfrac{x}{|x|}\right), & \text{if } |x| > r. \end{cases}$$

One can see that $\widetilde{F}$ is an integrably bounded u-Carathéodory map and

$$S(\widetilde{F},0,x_0) = S(F,0,x_0).$$

By Proposition 4.7, there exists an a.u.s.c. map $G : J \times \mathbb{R}^n \multimap \mathbb{R}^n$ with nonempty, convex, compact values such that $S(G,0,x_0) = S(\widetilde{F},0,x_0)$. Applying Proposition 4.8 to the map G, we obtain the sequence of maps G_k. As in Proposition 4.6, we see that $S(G,0,x_0)$ is an intersection of the decreasing sequence $S(G_k,0,x_0)$ of contractible sets. By the well-known Arzelà–Ascoli lemma and Theorem 4.6, we obtain that, for every $k \in \mathbb{N}$, the set $S(G_k,0,x_0)$ is compact and nonempty, which completes the proof. □

Using the above results and the unified approach to the u.s.c. and l.s.c. case due to A. Bressan (cf. [49,50]), we can obtain the following result.

PROPOSITION 4.9. *Let $G : J \times \mathbb{R}^n \multimap \mathbb{R}^n$ be a l.s.c. bounded map with nonempty closed values. Then there exists a u.s.c. map $F : J \times \mathbb{R}^n \multimap \mathbb{R}^n$ with compact convex values such that, for any $x_0 \in \mathbb{R}^n$, the set $S(G,0,x_0)$ contains an R_δ-set $S(F,0,x_0)$ as a subset.*

REMARK 4.7. In [22], topological structure of solution sets is also treated, provided F is not necessarily convex-valued. However, the absence of convexity seems to be a big handicap, because to prove the connectedness and compactness of the related solution set can be a difficult task (see, e.g., [22, Example 2.18 on p. 258]).

REMARK 4.8. It follows from the result in [98] (cf. also [55] or [78, Corollary 5.3.1], where mild solutions were considered for semilinear differential inclusions) that, in a real separable Banach space E, the solution sets to initial value problems are R_δ, provided conditions in Remark 4.6 hold. In general Banach spaces E, it is at least so when $F(t,.) : E \multimap E$ is completely continuous (cf. [58, Corollary 9.1(b) on pp. 118–119]).

We can also say something about the covering (topological) dimension of solution sets to the Cauchy problem (4.19).

Let Ω be an open set in $\mathbb{R}^{n+1}$ such that $[t_0, t_0+h] \times B(x_0, r) \subset \Omega$, where B denotes the closed ball centered at x_0 and with the radius r. Assume that $F : \Omega \multimap \mathbb{R}^n$ satisfies the following conditions:

(C1) the set of values of F is nonempty, compact and convex, for all $(t,x) \in \Omega$,
(C2) $F(t,\cdot) : B(x_0,r) \multimap \mathbb{R}^n$ is continuous, for a.a. $t \in [t_0, t_0+h]$,
(C3) $F(\cdot,x) : [t_0, t_0+h] \to \mathbb{R}^n$ is measurable, for all $x \in B(x_0,r)$,
(C4) there exist Lebesgue-integrable nonnegative functions $\alpha, \beta : [t_0, t_0+h] \to [0,\infty)$ such that, for any $x \in B(x_0,r)$, $|F(t,x)| \leqslant \alpha(t) + \beta(t)|x|$, for a.a. $t \in [t_0, t_0+h]$, where $|F(t,x)| \leqslant \sup\{|y| \mid y \in F(t,x)\}$.

Denote by $S([t_0, t_0+d], x_0)$ the set of solutions $x \in \mathrm{AC}([t_0, t_0+d], \mathbb{R}^n)$ of (4.19) on the interval $[t_0, t_0+d]$, $0 < d \leqslant h$.

The following two theorems are due to B.D. Gel'man [66] (cf. [22, Theorems 2.60 and 2.61 in Chapter III.2]).

THEOREM 4.10. *Let the assumptions* (C1)–(C4) *be satisfied. Assume that the set*

$$A = \bigl\{t \in [t_0, t_0+h] \mid \dim\bigl(F(t,x)\bigr) \geqslant 1,\ \textit{for any}\ x \in B(x_0,r)\bigr\}$$

is measurable and

$$\lim_{h\to 0} \frac{\mu(A \cap [t_0, t_0+h])}{h} > 0,$$

where $\dim(\cdot)$ *denotes the covering dimension and* $\mu(\cdot)$ *stands for the Lebesgue measure. Then there exists a number* d_0 *such that, for any* $0 < d \leqslant d_0$, *we have* $S = S([t_0, t_0+d], x_0) \neq \{\emptyset\}$ *and* $\dim(S) = \infty$.

THEOREM 4.11. *Let the assumptions of Theorem* 4.10 *be satisfied jointly with*
(C2′) $F(t,\cdot) : B(x_0,r) \multimap \mathbb{R}^n$ *is Lipschitz-continuous.*
Then there exists a number d_0 *such that, for any* $0 < d \leqslant d_0$, *any* $\varepsilon > 0$ *and any solution* $x \in S([t_0, t_0+d], x_0)$ $(\neq \{\emptyset\})$, *we have* $\dim(S_{x,\varepsilon}) = \infty$, *where* $S_{x,\varepsilon} = \{y \in S \mid \|x-y\| \leqslant \varepsilon\}$.

Now, we shall study the reverse Cauchy problem when, instead of the origin, the value of solutions is prescribed at infinity, namely

$$\begin{cases} \dot{x}(t) \in F\bigl(t, x(t)\bigr), & \text{for a.a. } t \in [0,\infty), \\ \lim\limits_{t\to\infty} x(t) = x_\infty \in \mathbb{R}^n, \end{cases} \tag{4.22}$$

where $F : [0,\infty) \times \mathbb{R}^n \multimap \mathbb{R}^n$ is a u-Carathéodory map, i.e.

(i) values of F are nonempty, compact and convex, for all $(t, x) \in [0, \infty) \times \mathbb{R}^n$,
(ii) $F(t, \cdot)$ is upper semicontinuous, for a.a. $t \in [0, \infty)$,
(iii) $F(\cdot, x)$ is measurable, for all $x \in \mathbb{R}^n$.

We will prove acyclicity of the solution set of problem (4.22).

Recalling that any contractible set is acyclic, we can give

THEOREM 4.12. *Consider the target* (*terminal*) *problem* (4.22), *where* $F : [0, \infty) \times \mathbb{R}^n \multimap \mathbb{R}^n$ *is a u-Carathéodory map and* $x_\infty \in \mathbb{R}^n$ *is arbitrary. Assume that there exists a globally integrable function* $\nu : [0, \infty) \to [0, \infty)$, *where* $\int_0^\infty \nu(t)\,\mathrm{d}t = E < 1$, *such that*

$$d_H\big(F(t, x), F(t, y)\big) \leqslant \nu(t)|x - y|, \quad \textit{for all } t \in [0, \infty) \textit{ and } x, y \in \mathbb{R}^n. \tag{4.23}$$

Moreover, assume that $d_H(F(\cdot, 0), 0)$ *can be absolutely estimated by some globally integrable function. If* E *is a sufficiently small constant, then the set of solutions to problem* (4.22) *is compact and acyclic, for every* $x_\infty \in \mathbb{R}^n$.

PROOF. Observe that condition (4.23) implies the existence a globally integrable function $\alpha : [0, \infty) \to [0, \infty)$ and a positive constant B such that

$$\big|F(t, x)\big| \leqslant \alpha(t)\big(B + |x|\big), \quad \text{for every } x \in \mathbb{R}^n \text{ and a.a. } t \in [0, \infty), \tag{4.24}$$

where $|F(t, x)| = \sup\{|y| \mid y \in F(t, x)\}$. Thus, problem (4.22) can be equivalently replaced by the problem

$$\begin{cases} \dot{x}(t) \in G\big(t, x(t)\big), & \text{for a.a. } t \in [0, \infty), \\ \lim\limits_{t \to \infty} x(t) = x_\infty \in \mathbb{R}^n, \end{cases} \tag{4.25}$$

where G is a suitable Carathéodory map which can be estimated by a sufficiently large positive constant M, i.e.

$$\big|G(t, x)\big| \leqslant M, \quad \text{for every } x \in \mathbb{R}^n \text{ and a.a. } t \in [0, \infty),$$

and which satisfies condition (4.23) as well. In other words, the solution set $\mathcal{S}$ for problem (4.22) is the same as for problem (4.25), where

$$\mathcal{S} = \big\{x \in C\big([0, \infty), \mathbb{R}^n\big) \mid \dot{x}(t) \in F\big(t, x(t)\big), \\ \text{for a.a. } t \in [0, \infty) \text{ and } x(\infty) = x_\infty\big\}.$$

For the structure of $\mathcal{S}$, we will modify the approach from above. Observe that, under the above assumptions, F as well G are well known to be product-measurable (see Proposition 2.4), and subsequently having a Carathéodory selection $g \subset G$ which is Lipschitzian with a not necessarily same, but again sufficiently small constant (see, e.g., [73, pp. 101–103]). By the sufficiency we mean that, besides others,

$$\big|g(t, x) - g(t, y)\big| \leqslant \gamma(t)|x - y|$$

holds, for all $x, y \in \mathbb{R}^n$ and a.a. $t \in [0, \infty)$, with a Lebesgue integrable function $\gamma : [0, \infty) \to [0, \infty)$ such that $\int_0^\infty \gamma(t)\,\mathrm{d}t < 1$.

Considering the single-valued problem ($g \subset G$)

$$\begin{cases} \dot{x}(t) = g\bigl(t, x(t)\bigr), & \text{for a.a. } t \in [0, \infty), \\ \lim\limits_{t\to\infty} x(t) = x_\infty, \end{cases} \tag{4.26}$$

we can easily prove the existence of a unique solution $\overline{x}(t)$ of problem (4.26). The uniqueness can be verified in a standard manner by the contradiction, when assuming the existence of another solution $\overline{y}(t)$ of that problem, because so we would arrive at the false inequality

$$\begin{aligned} \sup_{t\in[0,\infty)} \bigl|\overline{x}(t) - \overline{y}(t)\bigr| &= \sup_{t\in[0,\infty)} \left| \int_\infty^t g\bigl(s, \overline{x}(s)\bigr)\,\mathrm{d}s - \int_\infty^t g\bigl(s, \overline{y}(s)\bigr)\,\mathrm{d}s \right| \\ &\leqslant \int_0^\infty \bigl|g\bigl(s, \overline{x}(s)\bigr) - g\bigl(s, \overline{y}(s)\bigr)\bigr|\,\mathrm{d}t \\ &\leqslant \int_0^\infty \gamma(t) \sup_{t\in[0,\infty)} \bigl|\overline{x}(t) - \overline{y}(t)\bigr|\,\mathrm{d}t \\ &\leqslant \sup_{t\in[0,\infty)} \bigl|\overline{x}(t) - \overline{y}(t)\bigr| \int_0^\infty \gamma(t)\,\mathrm{d}t \\ &< \sup_{t\in[0,\infty)} \bigl|\overline{x}(t) - \overline{y}(t)\bigr|. \end{aligned}$$

Hence, according to the definition of contractibility in Section 2.1, it is sufficient to show that the solution set $\mathcal{S}$ of problem (4.25) is homotopic to a unique solution $\overline{x}(t)$ of problem (4.26), which is at the same time a solution of problem (4.25) as well. The desired homotopy reads ($\lambda \in [0, 1]$)

$$h(x, \lambda)(t) = \begin{cases} x(t), & \text{for } t \geqslant 1/\lambda - \lambda,\ \lambda \neq 0, \\ \overline{z}(t), & \text{for } 0 < t \leqslant 1/\lambda - \lambda,\ \lambda \neq 0, \\ \overline{x}(t), & \text{for } \lambda = 0, \end{cases}$$

where $\overline{z}$ is a unique solution to the reverse Cauchy problem

$$\begin{cases} \dot{x}(t) = g\bigl(t, z(t)\bigr), & \text{for a.a. } t \in [0, 1/\lambda - \lambda], \\ z(1/\lambda - \lambda) = x(1/\lambda - \lambda), \end{cases}$$

for each $\lambda \in [0, 1]$. Then h is a continuous homotopy such that $h(x, 0) = \overline{x}$, $h(x, 1) = x$, as required, and subsequently, the set $\mathcal{S}$ is acyclic. Using the convexity assumption on values of F, we can prove by the standard manner [22, Mazur's Theorem 1.33 in Chapter I.1] that $\mathcal{S}$ is closed in $C([0, \infty), \mathbb{R}^n)$. By Arzelà–Ascoli's lemma, this set is compact, and the proof is complete. □

Now, we shall consider the boundary value problem

$$\begin{cases} \dot{x}(t) + A(t)x(t) \in F\big(t, x(t)\big), & \text{for a.a. } t \in [0, T], \\ Lx = r, \end{cases} \tag{4.27}$$

where

(i) $A : [0, T] \to \mathcal{L}(\mathbb{R}^n, \mathbb{R}^n)$ is a measurable linear operator such that $|A(t)| \leqslant \gamma(t)$, for all $t \in [0, T]$ and some integrable function $\gamma : [0, T] \to [0, \infty)$,

(ii) the associated homogeneous problem

$$\begin{cases} \dot{x}(t) + A(t)x(t) = 0, & \text{for a.a. } t \in [0, T], \\ Lx = 0 \end{cases}$$

has only the trivial solution,

(iii) $F : [0, T] \times \mathbb{R}^n \multimap \mathbb{R}^n$ has nonempty, compact, convex values,

(iv) $F(\cdot, x)$ is measurable, for every $x \in \mathbb{R}^n$,

(v) there is a constant $M \geqslant 0$ such that

$$d_H\big(F(t, x), F(t, y)\big) \leqslant M|x - y|, \quad \text{for all } x, y \in \mathbb{R}^n \text{ and a.a. } t \in [0, T],$$

where d_H stands for the Hausdorff metric,

(vi) there are two nonnegative Lebesgue-integrable functions $\delta_1, \delta_2 : [0, T] \to [0, \infty)$ such that,

$$\big|F(t, x)\big| \leqslant \delta_1(t) + \delta_2(t)|x|, \quad \text{for a.a. } t \in [0, T] \text{ and all } x \in \mathbb{R}^n,$$

where $|F(t, x)| = \sup\{|y| \mid y \in F(t, x)\}$.

In [43], the authors have proved the functional generalization of following theorem.

THEOREM 4.13. *Under the assumptions* (i)–(vi), *a certain "critical" value* λ *exists such that if* $M < \lambda$, *then the set of solutions of* (4.27) *is a* (*nonempty*) *compact AR-space*. *Moreover, if the Lebesgue measure of the set* $\{t \mid \dim F(t, x) < 1,$ *for some* $x \in \mathbb{R}\}$ *is still zero, then the set of solutions of* (4.27) *is an infinite dimensional compact AR-space*, *where* $\dim X$ *denotes the covering* (*topological*) *dimension of a space* X.

REMARK 4.9. Observe that for $A \equiv 0$ and $Lx = x(0)$, the related Cauchy problem can have, under the assumptions of Theorem 4.13, infinitely many linearly independent solutions on the whole interval $[0, T]$.

REMARK 4.10. The first assertion of Theorem 4.13 can be still improved (see [22, Theorem 3.13 in Chapter III.3]), namely that, for the problem

$$\begin{cases} \dot{x}(t) + A(t)x(t) \in \alpha F\big(t, x(t)\big), & \text{for a.a. } t \in [0, T], \\ Lx = \theta, \end{cases} \tag{4.28}$$

where $\alpha \leqslant \lambda$, when λ is the critical value in Theorem 4.13, the set of solutions of (4.28) is nonempty, compact and acyclic.

REMARK 4.11. In the case of ODEs, the solution set in Theorem 4.13 consists, unlike in the critical case for $\alpha = \lambda$ in Remark 4.10, of a unique solution. The same is true for Theorem 4.12.

In view of Remark 4.11, a nontrivial structure of solution sets to single-valued boundary problems can be seen as a delicate problem. The following result in this field in [46] is rather rare.

THEOREM 4.14. *Consider the Floquet problem*

$$\begin{cases} \dot{x}(t) = f\big(t, x(t)\big), & \text{for a.a. } t \in [a,b], \\ x(a) + \lambda x(b) = \xi & \big(\lambda > 0, \xi \in \mathbb{R}^n\big), \end{cases} \tag{4.29}$$

where $f : [a,b] \times \mathbb{R}^n \to \mathbb{R}^n$ *is a bounded Carathéodory function. Assume, furthermore, that* f *satisfies*

$$\big|f(t,x) - f(t,y)\big| \leqslant p(t)|x-y|, \quad \text{for a.a. } t \in [a,b] \text{ and } x, y \in \mathbb{R}^n, \tag{4.30}$$

where $p : [a,b] \to [0,\infty)$ *is a Lebesgue-integrable function such that*

$$\int_a^b p(t)\,\mathrm{d}t \leqslant \sqrt{\pi^2 + \ln^2 \lambda}. \tag{4.31}$$

Then the set of solution to (4.29) *is an* R_δ*-set.*

REMARK 4.12. As pointed out in [46], if the sharp inequalities take place in (4.31), then problem (4.29) has a unique solution. On the other hand, for equalities (4.31), problem (4.29) can possess more solutions, respectively.

Unlike in the above theorems, the following problems can be regarded as those with "limiting" boundary conditions. In [53], the following result has been proved (as Theorem 3.1) for the boundary value problem

$$\begin{cases} \dot{x} = f(t,x), \\ Lx = r, \end{cases} \tag{4.32}$$

where $f : I \times \mathbb{R}^n \to \mathbb{R}^n$ is a continuous function, $L : C^1(I, \mathbb{R}^n) \to \mathbb{R}^n$ is a linear operator and $I = [a,b]$ is a compact interval.

PROPOSITION 4.10. *Let* $f : I \times \mathbb{R}^n \to \mathbb{R}^n$ *be a fixed continuous function such that, for every* $t_0 \in I$ *and* $x_0 \in \mathbb{R}^n$, *there exists a unique* (*smooth*) *solution* $x(t)$ *of the equation* $\dot{x} = f(t,x)$, *satisfying* $x(t_0) = x_0$.

Let $\mathcal{U}$ *be an open* (*in the norm topology*) *subset of the Banach space of all continuous linear operators* $L : C_1^0(I, \mathbb{R}^n) \to \mathbb{R}^n$, *where* C_1^0 *denotes the set* $C^1(\mathbb{R}^n) \subset C^0(I, \mathbb{R}^n)$, *topologized by the induced topology of* $C^0(I, \mathbb{R}^n)$ $(:= C(I, \mathbb{R}))$.

If, for every $L \in \mathcal{U}$ *and* $r \in \mathbb{R}^n$, *the boundary value problem* (4.32) *has at most one solution, then, for every* $L \in \mathcal{U}$ *and* $r \in \mathbb{R}^n$, *problem* (4.32) *has exactly one solution.*

Our aim is to prove, by means of Proposition 2.6 in Section 2.3, the following theorem.

THEOREM 4.15. *Let* $f : I \times \mathbb{R}^n \to \mathbb{R}^n$ *be a fixed continuous function and* $p : I \to \mathbb{R}^n$ *be a continuous function such that, for every* $t_0 \in I$, $x_0 \in \mathbb{R}^n$ *and* $p \in C(I, \mathbb{R}^n)$ *with* $\|p\| \leqslant 1$, *there exists a unique solution* $x(t)$ *of*

$$\dot{x} = f(t, x) + p(t), \tag{4.33}$$

satisfying $x(t_0) = x_0$.

Let $\mathcal{U}$ *be an open* (*in the norm topology*) *subset of the Banach space of all continuous linear operators* $L : C_1^0(I, \mathbb{R}^n) \to \mathbb{R}^n$, *where* C_1^0 *has the same meaning as in Proposition* 4.10.

Assume that, for every $L \in \mathcal{U}$, $r \in \mathbb{R}^n$ *and* $p \in C^1(\mathbb{R}^n)$ *with* $\|p\| \leqslant 1$, *the boundary value problem*

$$\begin{cases} \dot{x} = f(t, x) + p(t), \\ Lx = r, \end{cases} \tag{4.34}$$

has at most one solution and that, for every $L \in \overline{\mathcal{U}}$, *all solutions of problem* (4.32) *are uniformly* (*i.e. independently of* $L \in \overline{\mathcal{U}}$) *a priori bounded, where* $\overline{\mathcal{U}}$ *denotes the closure of* $\mathcal{U}$ *in the* C_0^1*-topology.*

Then, for every $L \in \partial\mathcal{U}$ *and* $r \in \mathbb{R}^n$, *where* $\partial\mathcal{U}$ *denotes the boundary of* $\mathcal{U}$ *in the* C_1^0*-topology, problem* (4.32) *has an* R_δ*-set of solutions.*

PROOF. Since all assumptions of Proposition 4.10 are satisfied, problem (4.34) is solvable, for every $L \in \mathcal{U}$, $r \in \mathbb{R}^n$ and $p \in C(I, \mathbb{R}^n)$ with $\|p\| \leqslant 1$.

Furthermore, since $\overline{\mathcal{U}}$ is a closed subset of the Banach space of all continuous linear operators, each element $\widetilde{L} \in \partial\mathcal{U}$ can be regarded as a uniform limit of a suitable sequence $\{L_k\}$ such that $\widetilde{L} = \lim_{k\to\infty} L_k$, where $L_k \in \mathcal{U}$ $(= \operatorname{int}\mathcal{U})$, for every $k \in \mathbb{N}$.

Fix such an $\widetilde{L} \in \partial\mathcal{U}$ and consider the compact operators Φ_k, $\Phi : \mathcal{B} \to C_1^0(I, \mathbb{R}^n)$:

$$\Phi_k(x)(t) = x(a) + L_k x - r + \int_a^t f\bigl(s, x(s)\bigr)\,\mathrm{d}s$$

and

$$\Phi(x)(t) = x(0) + \widetilde{L}x - r + \int_a^t f\bigl(s, x(s)\bigr)\,\mathrm{d}s,$$

where $\mathcal{B} \subset C^0(I, \mathbb{R}^n)$ is a suitable closed ball centered at the origin, which is implied by the assumption of a uniform a priori boundedness of solutions. The compactness of operators follows directly by means of the well-known Arzelà–Ascoli lemma.

One can readily check the one-to-one correspondence between the fixed points of Φ and the solutions of problem (4.32) as well as those of Φ_k and the solutions of the equation $\dot{x} = f(t, x(t))$, satisfying

$$L_k x = r.$$

Thus, one can associate to Φ_k and Φ the proper maps $\varphi_k = \mathrm{id} - \Phi_k$ and $\varphi = \mathrm{id} - \Phi$, respectively, where id denotes the identity, namely

$$\varphi_k(x)(t) = x(t) - x(a) - L_k x + r - \int_a^t f\big(s, x(s)\big)\,\mathrm{d}s$$

and

$$\varphi(x)(t) = x(t) - x(a) - \widetilde{L}x + r - \int_a^t f\big(s, x(s)\big)\,\mathrm{d}s.$$

So, the nonempty kernel $\varphi^{-1}(0)$ of φ corresponds to the fixed points of Φ, and subsequently to solutions of (4.32), i.e.

$$x \in \Phi(x) \quad \Longleftrightarrow \quad 0 \in x - \Phi(x) = (\mathrm{id} - \Phi)(x) = \varphi(x).$$

We can assume without any loss of generality that, for a sufficiently large $k \in \mathbb{N}$, we have

$$\big|\varphi_k(x)(t) - \varphi(x)(t)\big| = \big|L_k x - \widetilde{L}x\big| = \big|\big(L_k - \widetilde{L}\big)x\big| \leqslant \frac{1}{k}, \tag{4.35}$$

because, otherwise, we can obviously select a subsequence with this property.

Since $\|\varphi_k(x)(t) - \varphi(x)(t)\| \leqslant 1/k$ holds, for every $x \in \mathcal{B}$, condition (i) of Proposition 2.6 in Section 2.3 is satisfied.

In order to prove (ii) in Proposition 2.6, it is sufficient to verify the following inequalities

$$\big|\varphi_k(x)(t)\big| \leqslant \frac{1}{k} \quad \text{and} \quad \big|\big(\varphi_k(x)\big)(t)\big| \leqslant \frac{1}{k}, \quad k \in \mathbb{N},$$

for every x with $\varphi(x) = 0$.

However, since $(\varphi_k(x))(t) = \dot{x}(t) - f(t, x(t)) = 0$, $k \in \mathbb{N}$, and the first inequality follows from (4.35), we are done.

In order to verify (iii) in Proposition 2.6, we should realize that, for any $u \in V_k = \{u \in C^1(I, \mathbb{R}^n) : \|u\|_{C^0} \leqslant 1/k$ and $\|\dot{u}\|_{C^0} \leqslant 1/k\}$, for some $k \in \mathbb{N}$, $x(t)$ is a solution of the equation $u(t) = \varphi_k(x)(t)$, i.e.

$$u(t) = x(t) - x(a) - L_k x + r - \int_a^t f\big(s, x(s)\big)\,\mathrm{d}s,$$

if and only if it satisfies

$$\begin{cases} \dot{x} = \dot{u}(t) + f(t, x), \\ L_k x = r - u(a). \end{cases} \tag{4.36}$$

By the hypothesis, problem (4.36) has a unique solution, for every $L_k \in \mathcal{U}$, $r \in \mathbb{R}^n$ and $u \in C^1(I, \mathbb{R}^n)$ with $\|u\| \leqslant 1$, as required. Therefore, applying Proposition 2.6 in Section 2.3, the set $\{\varphi(0)\}$ is R_δ. In other words, the solution set of the original problem (4.32) is R_δ as well. □

REMARK 4.13. One can observe that the sole existence can be easily proved by means of the well-known Schauder fixed point theorem.

EXAMPLE 4.1. According to Example 2 in [85], problem

$$\begin{cases} \dot{x}_i = f_i(t, x_1, x_2) + p_i(t), \quad i = 1, 2, \\ ax_1(0) + x_2(0) = r_1, \quad bx_1(1) + x_2(1) = r_2, \end{cases} \tag{4.37}$$

is uniquely solvable, for every $a^2 < 1$, $b^2 > 1$, $r_i \in \mathbb{R}$ $(i = 1, 2)$ and $p = (p_1, p_2) \in C([0, 1], \mathbb{R})$, provided $f_i \in C^1([0, 1], \mathbb{R})$, $i = 1, 2$, and

$$\frac{\partial f_1}{\partial x_1} u_1^2 + \frac{\partial f_1}{\partial x_2} u_1 u_2 - \frac{\partial f_2}{\partial x_1} u_1 u_2 - \frac{\partial f_2}{\partial x_2} u_2^2 \geqslant 0 \quad (i = 1, 2),$$

for each triple $(t, x_1, x_2) \in [0, 1] \times \mathbb{R}^2$ and each double $(u_1, u_2) \in \mathbb{R}^2$.

Therefore, according to Theorem 4.15 (more precisely, according to its modified version, where the set of all continuous linear operators can be restricted (see [85]) to the set of all real $(n \times n)$-matrices), problem

$$\begin{cases} \dot{x}_i = f_i(t, x_1, x_2), \quad i = 1, 2, \\ ax_1(0) + x_2(0) = r_1, \quad bx_1(1) + x_2(1) = r_2, \end{cases} \tag{4.38}$$

has an R_δ-set of solutions, for certain $(a, b) \in \mathbb{R}^2$ in a closed subset of $\mathbb{R}^2$ with $a^2 = 1$, $b^2 \geqslant 1$ or $a^2 \leqslant 1$, $b^2 = 1$ (r_1, r_2 can be arbitrary), whenever all solutions of problem (4.38) are uniformly a priori bounded, for such $a^2 \leqslant 1$, $b^2 \geqslant 1$.

This can be achieved for $a \neq b$, i.e. particularly with the exception of $a = b = 1$ or $a = b = -1$, and $b^2 \leqslant b_*^2$, for some $b_* > 1$, when, e.g.,

$$\left| f(t, x) \right| \leqslant \alpha |x| + \beta, \quad \text{for all } (t, x) \in [0, 1] \times \mathbb{R}^2, \tag{4.39}$$

where α, β are suitable nonnegative constants (α must be sufficiently small as below) and $x = (x_1, x_2)$, $f = (f_i, f_2)$.

Indeed. Since the linear homogeneous problem

$$\begin{cases} \dot{x}_i = 0, \quad i = 1, 2, \\ ax_1(0) + x_2(0) = 0, \quad bx_1(1) + x_2(1) = 0, \end{cases}$$

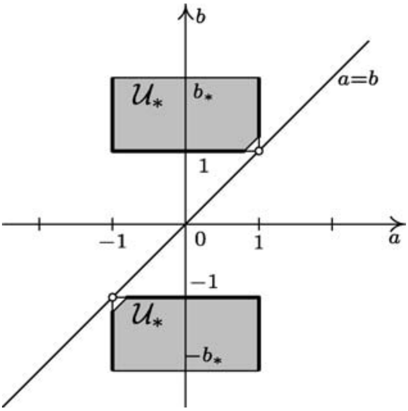

Fig. 2.

has for $a \neq b$ obviously only a trivial solution, every solution $x(t) = (x_1(t), x_2(t))$ of (4.38) takes the form (see, e.g., [22, Lemma 5.136 in Chapter III.5])

$$x_i(t) = \int_0^1 G_i(t, s, a, b) f_i\bigl(s, x_1(s), x_2(s)\bigr)\,\mathrm{d}s + \widetilde{x}_i, \quad i = 1, 2,$$

where $G = (G_1, G_2)$ is the related Green function of the linearized problem (4.38), namely

$$\begin{cases} \dot{x}_i = f_i(t, x_1, x_2), \quad i = 1, 2, \\ ax_1(0) + x_2(0) = 0, \quad bx_1(1) + x_2(1) = 0, \end{cases}$$

i.e.

$$G(t, s, a, b) = \begin{cases} \dfrac{1}{b-a}\begin{pmatrix} b & 1 \\ -ab & -a \end{pmatrix}, & \text{for } 0 \leqslant t \leqslant s \leqslant 1, \\ \dfrac{1}{b-a}\begin{pmatrix} a & 1 \\ -ab & -b \end{pmatrix}, & \text{for } 0 \leqslant s \leqslant t \leqslant 1, \end{cases}$$

and $\widetilde{x} = (\widetilde{x}_1, \widetilde{x}_2)$ is a unique solution of the problem

$$\begin{cases} \dot{x}_i = 0, \quad i = 1, 2, \\ ax_1(0) + x_2(0) = r_1, \quad bx_1(1) + x_2(1) = r_2, \end{cases}$$

i.e. $\widetilde{x}_1 = (r_2 - r_1)/(b - a)$, $\widetilde{x}_2 = r_1 - a(r_2 - r_1)/(b - a)$.

Let us fix (a, b) at the boundary $\partial\mathcal{U} = \{(a, b) \in \mathbb{R}^2 \mid a^2 = 1,\ b^2 \geqslant 1 \text{ or } a^2 \leqslant 1,\ b^2 = 1\}$ with $a \neq b$, for which we intend to get the result and cut off appropriately the corners with $a = b$, jointly with those (a, b) with $b^2 > b_*^2$ for some $b_* > 1$, as in Fig. 2. The bold curve in Fig. 2 so indicates the part of the boundary of our interest.

Denoting $g = \max_{(a,b)\in\overline{\mathcal{U}}_*} g_{a,b}$, $g_{a,b} = \max_{t,s\in[0,1]} |G(t,s,a,b)|$, where $\overline{\mathcal{U}}_*$ is indicated in Fig. 2 by the shaded region (observe that since $\overline{\mathcal{U}}_*$ is compact, g certainly exists), we obtain by means of (4.39) that

$$\|x(t)\| \leqslant g\big(\alpha\|x(t)\| + \beta\big) + \max_{(a,b)\in\overline{\mathcal{U}}_*} |\widetilde{x}|,$$

i.e.

$$\|x(t)\| \leqslant \frac{\beta g + \max_{(a,b)\in\overline{\mathcal{U}}_*} |\widetilde{x}|}{1 - \alpha g},$$

whenever $\alpha < g^{-1}$, as claimed. This completes the example.

REMARK 4.14. One can easily check that, for fixed values of $(a,b) \in \partial\mathcal{U}$ with $a \neq b$, the condition $\alpha < g^{-1}$ can take, e.g., the form

$$\alpha < \frac{|b-a|}{|b| + \max(1, |ab|)}.$$

A continuous function $f : I \times \mathbb{R}^n \to \mathbb{R}^n$ can be approximated with an arbitrary accuracy by locally Lipschitzian (in the second variable) functions (see, e.g., [22, Theorem 3.37 in Chapter I.3] or [71]), say $(f + \varepsilon_k)$, $k \in \mathbb{N}$, such that $\lim_{k\to\infty} \|\varepsilon_k\| = 0$. Therefore, applying at first, for fixed $k \in \mathbb{N}$, Theorem 4.15 to the system

$$\dot{x} = f(t,x) + \varepsilon_k(t,x), \tag{4.40}$$

we can still avoid (for more details, see [22, Chapter III.3]) the uniqueness assumption in Theorem 4.15 as follows.

THEOREM 4.16. *Let $f : I \times \mathbb{R}^n \to \mathbb{R}^n$ be a fixed continuous function and $\varepsilon_k : I \times \mathbb{R}^n \to \mathbb{R}^n$, $k \in \mathbb{N}$, be continuous functions with $\|\varepsilon_k\| \leqslant \varepsilon$ (ε – a sufficiently small constant) such that $(f + \varepsilon_k)(t,\cdot) : \mathbb{R}^n \to \mathbb{R}^n$, $k \in \mathbb{N}$, are locally Lipschitzian, for every $t \in I$, and $p : I \to \mathbb{R}^n$ be a continuous function with $\|p\| \leqslant 1$.*

Let $\mathcal{U}$ be an open (in the norm topology) subset of the Banach space of all continuous linear operators $L : C_1^0(I, \mathbb{R}^n) \to \mathbb{R}^n$.

Assume that, for every $L \in \mathcal{U}$, $r \in \mathbb{R}^n$, $k \in \mathbb{N}$ and $p \in C(I, \mathbb{R}^n)$ with $\|p\| \leqslant 1$, the boundary value problem

$$\begin{cases} \dot{x} = f(t,x) + \varepsilon_k(t,x) + p(t), \\ Lx = r \end{cases}$$

has at most one solution and that, for every $L \in \overline{\mathcal{U}}$ and $k \in \mathbb{N}$, all solutions of the problem

$$\begin{cases} \dot{x} = f(t,x) + \varepsilon_k(t,x), \\ Lx = r \end{cases}$$

are uniformly (*i.e. independently of* $L \in \overline{\mathcal{U}}$) *a priori bounded, where* $\overline{\mathcal{U}}$ *denotes the closure of* $\mathcal{U}$ *in the* C_1^0*-topology.*

Then, for every $L \in \partial\mathcal{U}$ *and* $r \in \mathbb{R}^n$, *where* $\partial\mathcal{U}$ *denotes the boundary of* $\mathcal{U}$ *in the* C_1^0*-topology, the problem* (4.32), *i.e.*

$$\begin{cases} \dot{x} = f(t,x), \\ Lx = r \end{cases}$$

has a (*nonempty*) *compact acyclic set of solutions.*

4.3. *Poincaré's operator approach*

By the Poincaré operators, we mean the *translation operators along the trajectories* of the associated differential systems. The translation operator is sometimes also called as *Poincaré–Andronov* or *Levinson* or, simply, *T-operator*.

In the classical theory, these operators are defined to be single-valued, when assuming among other things, the uniqueness of the initial value problems. At the absence of uniqueness, one usually approximates the right-hand sides of the given systems by the locally Lipschitzian ones (implying already uniqueness), and then applies the *standard limiting argument* (for more details, see, e.g., [71,81]).

On the other hand, set-valued analysis allows us to handle directly with multivalued Poincaré operators which become, under suitable natural restrictions imposed on the right-hand sides of given differential systems, admissible in the sense of Definition 2.5 in Section 2.2.

Hence, consider the u-Carathéodory system

$$\dot{x} \in F(t,x), \quad x \in \mathbb{R}^n, \tag{4.41}$$

where $F : [0,\tau] \times \mathbb{R}^n \multimap \mathbb{R}^n$ satisfies all conditions in Definition 2.10.

By a *solution* $x(t)$ of (4.41), we mean an absolutely continuous function $x(t) \in \mathrm{AC}([0,\tau],\mathbb{R}^n)$ satisfying (4.41), for a.a. $t \in [0,\tau]$, i.e. the one in the sense of Carathéodory, such solutions of (4.41) exist on $[0,\tau]$.

Hence, if $x(t,x_0) := x(t,0,x_0)$ is a solution of (4.41) with $x(0,x_0) = x_0 \in \mathbb{R}^n$, then the translation operator $T_\tau : \mathbb{R}^n \multimap \mathbb{R}^n$ at the time $\tau > 0$ along the trajectories of (4.41) is defined as follows:

$$T_\tau(x_0) := \{x(\tau,x_0) \mid x(\cdot,x_0) \text{ is a solution of (4.41) with } x(0,x_0) = x_0\}. \tag{4.42}$$

More precisely, T_τ can be considered as the composition of two maps, namely $T_\tau = \psi \circ \varphi$,

$$\mathbb{R}^n \overset{\varphi}{\multimap} \mathrm{AC}([0,\tau],\mathbb{R}^n) \xrightarrow{\psi} \mathbb{R}^n,$$

where $\varphi(x_0): x_0 \multimap \{x(t, x_0) \mid x(t, x_0)$ is a solution of (4.41) with $x(0, x_0) = x_0\}$ is well known to be an R_δ-mapping (see Theorem 4.5) and $\psi(y): y \to y(\tau)$ is obviously a continuous (single-valued) evaluation mapping.

In other words, we have the following commutative diagram:

$$\begin{tikzcd}
\mathbb{R}^n \arrow[r, multimap, "\varphi"] \arrow[dr, multimap, dotted, "T_\tau"'] & \mathrm{AC}\big([0, \tau], \mathbb{R}^n\big) \arrow[d, "\psi"] \\
& \mathbb{R}^n
\end{tikzcd}$$

The following characterization of T_τ has been proved on various levels of abstraction in several papers (see, e.g., [22, Theorem 4.3 in Chapter III.4] and the references therein).

THEOREM 4.17. *T_τ defined by* (4.42) *is admissible and admissibly homotopic* (*see Definitions* 2.5 *and* 2.6) *to identity. More precisely, T_τ is a composition of an R_δ-mapping and a continuous* (*single-valued*) *evaluation mapping.*

PROOF. According to Theorem 4.5, the mapping φ has an R_δ-set of values. We will show that it is u.s.c. by proving the closedness of the graph Γ_φ of φ (cf. Section 2.2).

Let $(x_n, y_n) \in \Gamma_\varphi$, i.e. $y_n \in \varphi(x_n)$, and $(x_n, y_n) \to (x, y)$ as $n \to \infty$. Since the functions y_n are absolutely continuous on $[0, \tau]$, the application of the well-known Gronwall inequality (see, e.g., [71]) leads to the estimates (cf. (iii) in Definition 2.10)

$$\|y_n\| \leqslant M := \sup_{n \in \mathbb{N}} \big(|x_n| + \gamma\tau\big) \exp(\gamma\tau) \quad \text{and} \quad \|\dot{y}_n\| \leqslant \gamma(1 + M),$$

where $\gamma = \max\{\alpha, \beta\}$. It follows that $\{y_n\}$ are equibounded.

Proposition 4.1 guarantees the existence of a sequence $\{y_n\}$ such that $y_n \to y$, uniformly, and $\dot{y}_n \to \dot{y}$, weakly in $L^1([0, \tau], \mathbb{R}^n)$. According to Mazur's theorem (see, e.g., [22, Theorem 1.33 in Chapter I.1]), $\dot{y}$ belongs to the strong closure $\dot{y} \in \overline{\mathrm{conv}}\{\dot{y}_n \mid n \geqslant l\}$, for all $l \geqslant 1$. Thus, there also exists a subsequence $\{z_l\}$ such that $z_l \to \dot{y}$, in the L^1-topology, where $z_l \in \overline{\mathrm{conv}}\{\dot{y}_n \mid n \geqslant l\}$. Moreover, there exists a subsequence (for the simplicity, denoted again by $\{z_l\}$) satisfying $z_l \to \dot{y}$, a.e. on $[0, \tau]$.

Let $I \subset [0, \tau]$ be a set of a full measure on $[0, \tau]$, i.e. $\mu(I) = \tau$, where μ denotes the Lebesgue measure, such that $z_l \to \dot{y}$ as $l \to \infty$, for all $t \in I$. It follows from the definition of z_l that $z_l(t) \in \sum_i \lambda_i F(t, y_{n_i}(t))$, where $\sum_i \lambda_i = 1$.

Since $F(t, \cdot)$ is u.s.c., for a.a. $t \in [0, \tau]$, and $y_{n_i}(t)$ is sufficiently close to $x(t)$ as well as $z_l(t)$ to $\dot{x}(t)$, we obtain

$$\dot{x}(t) \in \sum_i \lambda_i F\big(t, x(t)\big) + \varepsilon B$$

for an arbitrary $\varepsilon > 0$, where B is an open unit ball. This already means that $\dot{x}(t) \in F(t, x(t))$, and subsequently the graph Γ_φ of φ is closed. Since the arbitrary closed set

$\{(x, y), (x_1, y_1), \ldots, (x_n, y_n), \ldots\}$ is, according to the well-known Arzelà–Ascoli lemma, compact, φ is u.s.c.

For the remaining part of the proof, it is sufficient to consider the admissible homotopy $T_{\lambda\tau}$, $\lambda \in [0, 1]$. □

REMARK 4.15. Since a composition of admissible maps is admissible as well (see Section 2.2), T_τ can be still composed with further admissible maps ϕ such that $\phi \circ T_\tau$ becomes an (admissible) self-map on a compact ENR-space (i.e. homeomorphic to ANR in $\mathbb{R}^n$), for computation of the well-defined (cf. Section 3.1) generalized Lefschetz number:

$$\Lambda(\phi \circ T_\tau) = \Lambda(\phi).$$

T_τ considered on ENRs can be even composed, e.g., with suitable homeomorphisms $\mathcal{H}$ (again considered on ENRs), namely $\mathcal{H} \circ T_\tau$, for computation of the well-defined (cf. Section 3.3) fixed point index:

$$\operatorname{ind}(\mathcal{H} \circ T_\tau) = \operatorname{ind} \mathcal{H},$$

provided the fixed point set of $\mathcal{H} \circ T_{\lambda\tau}$ is compact, for $\lambda \in [0, 1]$.

REMARK 4.16. In [10] (cf. also [22, Chapter III.4]), translation operators are also studied, e.g., for systems with constraints, systems in Banach spaces, for directionally semicontinuous systems, etc. In particular, in real separable Banach spaces, one can check that, under the conditions in Remark 4.6 (cf. also Remark 4.8 and [58, Corollary 9.1 in Chapter 9.4]), the related translation operator T_τ is like in Theorem 4.17. In order T_τ to be also condensing, one should however impose some further restrictions. Since these restrictions are rather technical (cf. [78, Theorem 6.3.1] or [22, Theorem 4.16 in Chapter III.4]), and so this Poincaré's translation operator will not be more employed, we omit them here.

5. Existence results

5.1. *Existence of bounded solutions*

We start with the application of Theorem 4.4. Hence, let $(E, \|\cdot\|)$ be a reflexive Banach space and let $\mathcal{L}(E)$ be the space of all linear continuous transformations in E. The Hausdorff measure of noncompactness (MNC) will be denoted by γ.

We are interested in the existence of a bounded solution to the semilinear differential inclusion

$$\dot{x}(t) + A(t)x(t) \in F\big(t, x(t)\big), \quad \text{for a.a. } t \in \mathbb{R} \tag{5.1}$$

with $A(t) \in \mathcal{L}(E)$ and a set-valued transformation F.

Our assumptions concerning the inclusion (5.1) will be the following:

(A1) $A:\mathbb{R}\to\mathcal{L}(E)$ is strongly measurable (cf. Definition 2.9) and Bochner integrable, on every compact interval $[a,b]$.

(A2) Assume that

$$\dot{x}+A(t)x=0 \tag{5.2}$$

admits a regular exponential dichotomy (cf. Remark 5.3 below; for more details see, e.g., [56]). Denote by G the principal Green's function for (5.2).

(F1) Let $F:\mathbb{R}\times E\multimap E$ be a u-Carathéodory set-valued map (cf. Definition 2.10) such that

$$\|F(t,x)\|\leqslant m(t),\qquad \text{for a.a. } t\in\mathbb{R},\ x\in E.$$

Here $m\in L^1_{\mathrm{loc}}(\mathbb{R})$ is such that, for a constant M,

$$\sup\left\{\int_t^{t+1}m(s)\,\mathrm{d}s\;\middle|\;t\in\mathbb{R}\right\}<M.$$

(F2) Assume that

$$\gamma\bigl(F(t,\Omega)\bigr)\leqslant g(t)h\bigl(\gamma(\Omega)\bigr),\qquad\text{for a.a. } t\in\mathbb{R}$$

and each bounded $\Omega\subset E$, where g,h, are positive functions, g is measurable, h is nondecreasing such that

$$L:=\sup\left\{\int_{\mathbb{R}}\|G(t,s)\|_{\mathcal{L}(E)}g(s)\,\mathrm{d}s\;\middle|\;t\in\mathbb{R}\right\}<\infty$$

and $qh(t)L<t$, for each $t>0$, with a constant $q=1$, if E is separable, and $q=2$, in the general case.

THEOREM 5.1. *Under the assumptions* (A1), (A2), (F1), (F2), *the semilinear differential inclusion* (5.1) *admits a bounded solution on* $\mathbb{R}$.

The main obstruction in the application of Theorem 4.4 will be the estimation of a suitably chosen MNC. For this purpose, we recall the following rule of taking the MNC under the sign of the integral (see [78, Corollary 4.2.5]).

LEMMA 5.1. *Let* $\{f_n\}\subset L^1([a,b],E)$ *be a sequence of functions such that*

(i) $\|f_n(t)\|\leqslant\nu(t)$, *for all* $n\in\mathbb{N}$ *and a.a.* $t\in[a,b]$, *where* $\nu\in L^1([a,b])$,

(ii) $\gamma(\{f_n(t)\})\leqslant c(t)$, *for a.a.* $t\in[a,b]$, *where* $c\in L^1([a,b])$.

Then we have the estimate

$$\gamma\left(\left\{\int_a^t f_n(s)\,\mathrm{d}s\right\}\right)\leqslant q\int_a^t c(s)\,\mathrm{d}s,$$

for each $t\in[a,b]$, *with* $q=1$, *if* E *is separable, and* $q=2$, *in general case.*

PROOF OF THEOREM 5.1. We carry out the proof in several steps.

(i) Let

$$Q := \left\{ x \in C(\mathbb{R}, E) \;\middle|\; \|x(t)\| \leqslant K, \text{ for each } t \in \mathbb{R},\ \|x(t_1) - x(t_2)\| \right.$$
$$\left. \leqslant K \int_{t_1}^{t_2} \|A(s)\|_{\mathcal{L}(E)}\, \mathrm{d}s + \int_{t_1}^{t_2} m(s)\, \mathrm{d}s, \text{ for all } t_1, t_2 \in \mathbb{R},\ t_1 \leqslant t_2 \right\}$$

with a constant K to be specified below. Clearly Q is a closed convex subset of $C(\mathbb{R}, E)$.

For a given $q \in Q$, we are interested in bounded solutions to the differential inclusion

$$\dot{x}(t) + A(t)x(t) \in F\bigl(t, q(t)\bigr), \quad \text{for a.a. } t \in \mathbb{R}. \tag{5.3}$$

Take $f \in N_F(q)$ (recall that such f exists, in view of Lemma 4.3), where N_F denotes the Nemytskiĭ operator. Since A admits an exponential dichotomy, we know that the problem

$$\dot{x}(t) + A(t)x(t) = f(t), \quad \text{for a.a. } t \in \mathbb{R},$$

has a unique, entirely bounded solution given by

$$x(f) = \int_{\mathbb{R}} G(t, s) f(s)\, \mathrm{d}s$$

(cf. [56,86]). Thus, problem (5.3) has a nonempty set of solutions $T(q)$. Using Lemmas 4.3 and 4.4, it is also clear that this set is closed convex, and since its compactness will become clear in the subsequent steps of the proof, it is in fact an R_δ-set.

(ii) We will show that, for each $q \in Q$, we actually have $T(q) \subset Q$. Let $x \in T(q)$. Then, for suitable $f \in N_F(q)$, we have

$$\begin{aligned}
\|x(t)\| &\leqslant \int_{\mathbb{R}} \|G(t, s)\|_{\mathcal{L}(E)} \|f(s)\|\, \mathrm{d}s \\
&\leqslant k \int_{-\infty}^{t} \mathrm{e}^{-\mu(t-s)} m(s)\, \mathrm{d}s + k \int_{t}^{\infty} \mathrm{e}^{-\mu(s-t)} m(s)\, \mathrm{d}s \\
&= k \sum_{j=0}^{\infty} \int_{j}^{j+1} \mathrm{e}^{-\mu\sigma} m(t-\sigma)\, \mathrm{d}\sigma + k \sum_{j=0}^{\infty} \int_{j}^{j+1} \mathrm{e}^{-\mu\sigma} m(t+\sigma)\, \mathrm{d}\sigma \\
&\leqslant k \sum_{j=0}^{\infty} \mathrm{e}^{-\mu j} \int_{j}^{j+1} m(t-\sigma)\, \mathrm{d}\sigma + k \sum_{j=0}^{\infty} \mathrm{e}^{-\mu j} \int_{j}^{j+1} m(t+\sigma)\, \mathrm{d}\sigma \\
&\leqslant k \sum_{j=0}^{\infty} \mathrm{e}^{-\mu j} \int_{t-j-1}^{t-j} m(s)\, \mathrm{d}s + k \sum_{j=0}^{\infty} \mathrm{e}^{-\mu j} \int_{t+j}^{t+j+1} m(s)\, \mathrm{d}s \\
&\leqslant 2kM \sum_{j=0}^{\infty} \mathrm{e}^{-\mu j} = 2kM\bigl(1 - \mathrm{e}^{-\mu}\bigr)^{-1} =: K.
\end{aligned} \tag{5.4}$$

In this estimation, we have used the fact that, by assumption (A2), there exist positive constants k, μ such that

$$\|G(t,s)\|_{\mathcal{L}(E)} \leqslant k\mathrm{e}^{-\mu|t-s|}.$$

Now, let $t_1, t_2 \in \mathbb{R}$. Then

$$\begin{aligned}\|x(t_1)-x(t_2)\| &\leqslant \int_{t_1}^{t_2} \|\dot{x}(s)\|\,\mathrm{d}s\\ &\leqslant \int_{t_1}^{t_2} \|A(s)\|_{\mathcal{L}(E)}\|x(s)\|\,\mathrm{d}s + \int_{t_1}^{t_2}\|f(s)\|\,\mathrm{d}s\\ &\leqslant K\int_{t_1}^{t_2}\|A(s)\|_{\mathcal{L}(E)}\,\mathrm{d}s + \int_{t_1}^{t_2} m(s)\,\mathrm{d}s.\end{aligned}$$

Consequently, $T(q) \subset Q$.

(iii) Let $\mathcal{M}$ be the power set of Q and define, for each $\Omega \in \mathcal{M}$, the real-valued MNC ψ by

$$\psi(\Omega) := \max_{D\in\mathcal{D}}(\Omega)\Bigl(\sup_{t\in\mathbb{R}}\gamma\bigl(D(t)\bigr)\Bigr),$$

where $\mathcal{D}(Q)$ denotes the collection of all denumerable subsets of Ω and $D(t) = \{d(t) \mid d \in D\} \subset E$. Then ψ is well-defined and from the corresponding properties of γ it is clear that ψ has monotone and nonsingular properties of measure of noncompactness (see Proposition 2.3 in Section 2.2). Finally, observe that ψ is regular in view of the Arzelà–Ascoli lemma.

We wish to show that the mapping T given in step (i) is condensing w.r.t. the MNC ψ.

Take $\Omega \in \mathcal{M}$. Considering $T(\Omega)$, we see that by the definition of ψ there exists a sequence $\{x_n\} \subset T(\Omega)$ such that

$$\psi\bigl(T(\Omega)\bigr) = \sup_{t\in\mathbb{R}}\gamma\bigl(\{x_n(t)\}\bigr).$$

Thus, for each $n \in \mathbb{N}$, there is $z_n \in \Omega$ and $f_n \in N_F(z_n)$ such that

$$x_n(t) = \int_{\mathbb{R}} G(t,s)f_n(s)\,\mathrm{d}s. \tag{5.5}$$

Let $\varepsilon > 0$ be fixed. Choose a number $a > 0$ such that $K\mathrm{e}^{-\mu a} < \varepsilon$. Analogously to the estimation (5.4), one shows that

$$\left\|\int_{-\infty}^{t-a} G(t,s)f_n(s)\,\mathrm{d}s + \int_{t+a}^{\infty} G(t,s)f_n(s)\,\mathrm{d}s\right\| \leqslant \varepsilon,$$

for every $n \in \mathbb{N}$. Using (5.5), we thus infer for an arbitrary $t \in \mathbb{R}$ that

$$\gamma\big(\{x_n(t)\}\big) \leqslant \varepsilon + \gamma\left(\left\{\int_{t-a}^{t+a} G(t,s) f_n(s)\,\mathrm{d}s\right\}\right).$$

Now, from assumption (F1), we get that

$$\big\|G(t,s) f_n(s)\big\| \leqslant \big\|G(t,s)\big\|_{\mathcal{L}(E)} m(s),$$

for a.a. $s \in \mathbb{R}$ and each $n \in \mathbb{N}$. Furthermore, using assumption (F2) and properties of γ (see Proposition 2.3 in Section 2.2), we see that the following estimate holds, namely

$$\begin{aligned}\gamma\big(\{G(t,s) f_n(s)\}\big) &\leqslant \big\|G(t,s)\big\|_{\mathcal{L}(E)} \gamma\big(\{f_n(s)\}\big)\\ &\leqslant \big\|G(t,s)\big\|_{\mathcal{L}(E)} g(s) h\big(\gamma\big(\{z_n(s)\}\big)\big)\\ &\leqslant \big\|G(t,s)\big\|_{\mathcal{L}(E)} g(s) h\big(\psi(\Omega)\big),\end{aligned}$$

for a.a. $s \in \mathbb{R}$. Hence, an application of Lemma 5.1 gives us

$$\gamma\big(\{x_n(t)\}\big) \leqslant \varepsilon + q h\big(\psi(\Omega)\big) \int_{t-a}^{t+a} \big\|G(t,s)\big\|_{\mathcal{L}(E)} g(s)\,\mathrm{d}s.$$

It follows that

$$\psi\big(T(\Omega)\big) \leqslant \varepsilon + q h\big(\psi(\Omega)\big) L,$$

and subsequently, since $\varepsilon > 0$ was arbitrary,

$$\psi\big(T(\Omega)\big) \leqslant q h\big(\psi(\Omega)\big) L. \tag{5.6}$$

Let us now assume that Ω is not relatively compact. Then $\psi(\Omega) > 0$ and so, by assumption (F2) and (5.6), we obtain

$$\psi\big(T(\Omega)\big) \leqslant \psi(\Omega).$$

Finally, observe that the estimate (5.6) also implies the quasi-compactness of the mapping T which subsequently justifies the compactness of the solution set to (5.3), as claimed.

Hence, we have verified all the assumptions of Theorem 4.4 (cf. also Definition 2.8) and we can establish the existence of a bounded solution to problem (5.1). □

REMARK 5.1. One can easily check that the assumption (F1) can be replaced by a weaker one, namely

$$\big\|F(t,x)\big\| \leqslant m(t) + K\|x\|, \quad \text{for a.a. } t \in \mathbb{R},\ x \in E, \tag{5.7}$$

where $K \geqslant 0$ is a sufficiently small constant and m is the same as above.

REMARK 5.2. If $A : E \to E$ is a linear, bounded operator whose spectrum does not intersect the imaginary axis, then the constant K in (5.7) can be easily taken as $K < 1/C(A)$, where

$$\sup_{t\in\mathbb{R}}\left|\int_{-\infty}^{\infty}\left\|G(t,s)\right\|\mathrm{d}s\right| \leqslant C(A), \quad G(t,s)=\begin{cases}\mathrm{e}^{-A(t-s)}P_-, & \text{for } t>s,\\ \mathrm{e}^{-A(t-s)}P_+, & \text{for } t<s\end{cases} \tag{5.8}$$

and P_-, P_+ stand for the corresponding spectral projections to the invariant subspaces of A.

REMARK 5.3. For $E = \mathbb{R}^n$ ($\Rightarrow$ (F2) holds automatically), condition (A2) is satisfied, provided there exists a projection matrix P ($P = P^2$) and constants $k > 0$, $\lambda > 0$ such that

$$\begin{cases}\left|X(t)PX^{-1}(s)\right| \leqslant k\exp\bigl(-\lambda(t-s)\bigr), & \text{for } s\leqslant t,\\ \left|X(t)(I-P)X^{-1}(s)\right| \leqslant k\exp\bigl(-\lambda(s-t)\bigr), & \text{for } t\leqslant s,\end{cases} \tag{5.9}$$

where $X(t)$ is the fundamental matrix of (5.2), satisfying $X(0) = I$, i.e., the unit matrix.

If A in (A1) is a piece-wise continuous and periodic, then it is well known that (5.9) takes place, whenever all the associated Floquet multiplies lie off the unit cycle. If A in (A1) is (continuous and) almost-periodic, then it is enough (see [93, p. 70]) that (5.9) holds only on a half-line $[t_0, \infty)$ or even on a sufficiently long finite interval.

Now, the information concerning the topological structure of solution sets in Section 4.2 will be employed for obtaining existence criteria, on the basis of general methods established in Section 4.1.

EXAMPLE 5.1. Consider the system

$$\begin{cases}\dot{x}_1 \in F_1(t,x_1,x_2)x_1 + F_2(t,x_1,x_2)x_2 + E_1(t,x_1,x_2),\\ \dot{x}_2 \in -F_2(t,x_1,x_2)x_1 + F_1(t,x_1,x_2)x_2 + E_2(t,x_1,x_2),\end{cases} \tag{5.10}$$

where $E_1, E_2, F_1, F_2 : [0,\infty) \times \mathbb{R}^2 \multimap \mathbb{R}^2$ are product-measurable u-Carathéodory maps.

Assume, furthermore, the existence of positive constants $\widetilde{E}_1$, $\widetilde{E}_2$, $\widetilde{F}_1$, $\widetilde{F}_2$, λ such that

$$\operatorname*{ess\,sup}_{t\in[0,\infty)}\Bigl[\sup_{|x_i|\leqslant D, i=1,2} F_1(t,x_1,x_2)\Bigr] \leqslant -\lambda, \tag{5.11}$$

$$\operatorname*{ess\,sup}_{t\in[0,\infty)}\Bigl[\sup_{|x_i|\leqslant D, i=1,2} \bigl|F_1(t,x_1,x_2)\bigr|\Bigr] \leqslant \widetilde{F}_1, \tag{5.12}$$

$$\operatorname*{ess\,sup}_{t\in[0,\infty)}\Bigl[\sup_{|x_i|\leqslant D, i=1,2} \bigl|F_2(t,x_1,x_2)\bigr|\Bigr] \leqslant \widetilde{F}_2, \tag{5.13}$$

$$\operatorname*{ess\,sup}_{t\in[0,\infty)}\Bigl[\sup_{|x_i|\leqslant D, i=1,2} \bigl|E_1(t,x_1,x_2)\bigr|\Bigr] \leqslant \widetilde{E}_1, \tag{5.14}$$

$$\operatorname*{ess\,sup}_{t\in[0,\infty)}\Big[\sup_{|x_i|\leqslant D, i=1,2}\big|E_2(t,x_1,x_2)\big|\Big]\leqslant\widetilde{E}_2, \tag{5.15}$$

where $D=1/\lambda(\widetilde{E}_1,\widetilde{E}_2)$. Observe that, under the assumptions (5.12)–(5.15), we have

$$\operatorname*{ess\,sup}_{t\in[0,\infty)}\big|\dot{x}_i(t)\big|\leqslant D',\quad i=1,2, \tag{5.16}$$

where $D'=(\widetilde{F}_1+\widetilde{F}_2)D+\max(\widetilde{E}_1,\widetilde{E}_2)$, so long as the solution $(x_1(t),x_2(t))$ of (5.10) satisfies

$$\sup_{t\in[0,\infty)}\big|x_i(t)\big|\leqslant D,\quad i=1,2. \tag{5.17}$$

Our aim is to prove, under the assumptions (5.11)–(5.15), the existence of a solution $x(t)=(x_1(t),x_2(t))$ satisfying

$$x(0)=0\quad\text{and}\quad\sup_{t\in[0,\infty)}\big|x_i(t)\big|\leqslant D,\quad i=1,2. \tag{5.18}$$

In order to apply Corollary 4.1 for this goal, define two sets

$$\begin{aligned}Q&:=\Big\{r(t)=\big(r_1(t),r_2(t)\big)\in C\big([0,\infty)\times[0,\infty),\mathbb{R}^2\big)\mid\sup_{t\in[0,\infty)}\big|r_i(t)\big|\leqslant D,\\&\qquad i=1,2\Big\},\\S&:=\big\{s(t)=\big(s_1(t),s_2(t)\big)\in C\big([0,\infty)\times[0,\infty),\mathbb{R}^2\big)\cap Q\mid\big|s_i(t)\big|\leqslant D't,\\&\qquad i=1,2\big\}\end{aligned}$$

(observe that $s(0)=0$), where Q is a closed convex subset of $C([0,\infty)\times[0,\infty),\mathbb{R}^2)$ and S is a bounded closed subset of Q.

For $q(t)=(q_1(t),q_2(t))\in Q$, consider still the family of systems

$$\begin{cases}\dot{x}_1=p_1(t)x_1+p_2(t)x_2+r_1(t),\\\dot{x}_2=-p_2(t)x_1+p_1(t)x_2+r_2(t),\end{cases} \tag{5.19}$$

where $p_1(t)\subset F_1(t,q(t))$, $p_2(t)\subset F_2(t,q(t))$, $r_1(t)\subset E_1(t,q(t))$, $r_2(t)\subset E_2(t,q(t))$ are measurable selections (see Proposition 2.5).

To show the solvability of (5.10) and (5.18) by means of Corollary 4.1, we need to verify that, for each $q\in Q$, the linearized system

$$\begin{cases}\dot{x}_1\in F_1\big(t,q(t)\big)x_1+F_2\big(t,q(t)\big)x_2+E_1\big(t,q(t)\big),\\\dot{x}_2\in -F_2\big(t,q(t)\big)x_1+F_1\big(t,q(t)\big)x_2+E_2\big(t,q(t)\big)\end{cases} \tag{5.20}$$

has an R_δ-set of solutions in S.

It is well known that the general solution $x(t,0,\xi)$ of (5.19), where $\xi = (\xi_1, \xi_2) \in \mathbb{R}^2$, reads as follows:

$$\begin{aligned}
x_1(t,0,\xi) = {} & \left[\xi_1 \cos\left(\int_0^t p_2(s)\,\mathrm{d}s\right) + \xi_2 \sin\left(\int_0^t p_2(s)\,\mathrm{d}s\right)\right] \exp\int_0^t p_1(s)\,\mathrm{d}s \\
& + \int_0^t \left[r_1(s) \exp\int_s^t p_1(w)\,\mathrm{d}w \cos\left(\int_s^t p_2(w)\,\mathrm{d}w\right)\right] \mathrm{d}s \\
& + \int_0^t \left[r_2(s) \exp\int_s^t p_1(w)\,\mathrm{d}w \sin\left(\int_s^t p_2(w)\,\mathrm{d}w\right)\right] \mathrm{d}s, \\
x_2(t,0,\xi) = {} & \left[-\xi_1 \sin\left(\int_0^t p_2(s)\,\mathrm{d}s\right) + \xi_2 \cos\left(\int_0^t p_2(s)\,\mathrm{d}s\right)\right] \exp\int_0^t p_1(s)\,\mathrm{d}s \\
& - \int_0^t \left[r_1(s) \exp\int_s^t p_1(w)\,\mathrm{d}w \sin\left(\int_s^t p_2(w)\,\mathrm{d}w\right)\right] \mathrm{d}s \\
& + \int_0^t \left[r_2(s) \exp\int_s^t p_1(w)\,\mathrm{d}w \cos\left(\int_s^t p_2(w)\,\mathrm{d}w\right)\right] \mathrm{d}s.
\end{aligned}$$

Because of (5.11), (5.14) and (5.15), we get

$$\begin{aligned}
& \sup_{t\in[0,\infty)} \left| \int_0^t \left[r_i(s)\,\mathrm{d}s \exp\int_s^t p_1(w)\,\mathrm{d}w \cos\left(\int_s^t p_2(w)\,\mathrm{d}w\right)\right] \mathrm{d}s \right| \\
& \quad \leqslant \widetilde{E}_i \sup_{t\in[0,\infty)} \int_0^t \exp\left[-\int_s^t \left|p_1(w)\right| \mathrm{d}w\right] \mathrm{d}s \leqslant \frac{\widetilde{E}_i}{\lambda}, \\
& \sup_{t\in[0,\infty)} \left| \int_0^t \left[r_i(s)\,\mathrm{d}s \exp\int_s^t p_1(w)\,\mathrm{d}w \sin\left(\int_s^t p_2(w)\,\mathrm{d}w\right)\right] \mathrm{d}s \right| \\
& \quad \leqslant \widetilde{E}_i \sup_{t\in[0,\infty)} \int_0^t \exp\left[-\int_s^t \left|p_1(w)\right| \mathrm{d}w\right] \mathrm{d}s \leqslant \frac{\widetilde{E}_i}{\lambda},
\end{aligned}$$

for $i = 1, 2$, and subsequently we arrive at

$$\sup_{t\in[0,\infty)} \left|x_i(t,0,\xi)\right| \leqslant |\xi_1| + |\xi_2| + D, \quad i = 1, 2, \tag{5.21}$$

and $x(0,0,\xi) = \xi$.

According to Theorem 4.9 (see also Proposition 2.5 and estimate (5.21)), problem (5.17) ∩ (5.20) has the R_δ-set of solutions $x(t,0,0)$. Moreover, in view of the indicated implication ((5.17) ⇒ (5.16)), these solutions $x(t,0,0)$ belong obviously to S, for every $q \in Q$, as required.

Thus, it follows from Corollary 4.1 that problem (5.10) ∩ (5.18) has, under the assumptions (5.11)–(5.15), at least one solution.

If the inequality (5.11) or both inequalities (5.14) and (5.15) are sharp, then the same conclusion is true for $x(0) = 0$ in (5.18) replaced by $x(0) = \xi$, where $|\xi|$ is sufficiently small. For bigger values of $|\xi|$, the above assumptions can be appropriately modified as well.

THEOREM 5.2. *Consider the target problem*

$$\begin{cases} \dot{x}(t) \in F\big(t, x(t)\big), & \textit{for a.a. } t \in [0, \infty), \\ \lim\limits_{t\to\infty} x(t) = x_\infty \in \mathbb{R}^n \end{cases} \tag{5.22}$$

and assume that $F : [0, \infty) \times \mathbb{R}^n \multimap \mathbb{R}^n$ *is a product-measurable u-Carathéodory map. Let, furthermore, there exist a globally integrable function* $\alpha : [0, \infty) \to [0, \infty)$ *and a positive constant* β *such that, for every* $x \in \mathbb{R}^n$ *and for a.a.* $t \in [0, \infty)$, *we have* $|F(t, x)| \leqslant \alpha(t)(\beta + |x|)$, *where* $|F(t, x)| = \sup\{|y| \mid y \in F(t, x)\}$, *and* $\int_0^\infty \alpha(t)\,\mathrm{d}t < \infty$. *Then problem* (5.22) *admits a* (*bounded*) *solution, for every* $x_\infty \in \mathbb{R}^n$.

PROOF. It is convenient to consider, instead of problem (5.22), the equivalent problem

$$\begin{cases} \dot{x}(t) \in G\big(t, x(t)\big), & \text{for a.a. } t \in [0, \infty), \\ \lim\limits_{t\to\infty} x(t) = x_\infty \in \mathbb{R}^n, \end{cases} \tag{5.23}$$

where

$$G(t, x) = \begin{cases} F(t, x), & \text{for } |x| \leqslant D \text{ and } t \in [0, \infty), \\ F\left(t, D\dfrac{x}{|x|}\right), & \text{for } |x| \geqslant D \text{ and } t \in [0, \infty), \end{cases}$$

$$D \geqslant \big(|x_\infty| + AB\big) \exp A, \qquad A = \int_0^\infty \alpha(t)\,\mathrm{d}t < \infty.$$

Moreover, there certainly exists a positive constant γ such that

$$|x_0| + \big|G(t, x)\big| \leqslant |x_0| + A(B + D) \leqslant \gamma, \\ \text{for all } x \in \mathbb{R}^n \text{ and a.a. } t \in [0, \infty). \tag{5.24}$$

Besides problem (5.23), consider still a one-parameter family of linear problems

$$\begin{cases} \dot{x}(t) \in G\big(t, q(t)\big), & \text{for a.a. } t \in [0, \infty),\ q \in Q, \\ x \in Q \cap S, \end{cases} \tag{5.25}$$

where

$$S = \Big\{x \in C\big([0, \infty), \mathbb{R}^n\big) \ \Big|\ \lim_{t\to\infty} x(t) = x_\infty\Big\},$$

$$Q = \big\{q \in C\big([0, \infty), \mathbb{R}^n\big) \ \big|\ \big|q(t)\big| \leqslant |x_\infty| + A(B + D),\ \text{for } t \geqslant 0\big\}.$$

Consider the set

$$S_1 = \left\{ x \in Q \;\middle|\; \left|x(t) - x_\infty\right| \leqslant (B + D) \int_t^\infty \alpha(s)\,\mathrm{d}s, \text{ for } t \geqslant 0 \right\} \subset S.$$

It is evident that S_1 is a closed subset of S and all solutions to problem (5.25) belong to S_1.

At first, we assume that $G = g$ is single-valued. Then we have a single-valued continuous operator

$$T(q) = x_\infty + \int_\infty^t g\big(s, q(s)\big)\,\mathrm{d}s, \quad \text{for every } q \in Q.$$

Thus, to apply Corollary 4.2, only the condition $T(Q) \subset Q$ should be verified. But this follows immediately from (5.24), because

$$\begin{aligned} \sup_{t \in [0,\infty)} \left| x_\infty + \int_\infty^t G\big(s, q(s)\big)\,\mathrm{d}s \right| &\leqslant |x_\infty| + \int_0^\infty \big|G\big(t, q(t)\big)\big|\,\mathrm{d}t \\ &\leqslant |x_\infty| + (B + D) \int_0^\infty \alpha(t)\,\mathrm{d}t \\ &= |x_\infty| + A(B + D) < \infty. \end{aligned} \tag{5.26}$$

By Corollary 4.2, we obtain a solution to the problem with g as a right-hand side. This existence result can be used jointly with Theorem 4.12 which is needed to prove our statement in a general case. In fact, in view of the (just proved) existence result and Theorem 4.12 (cf. also Proposition 2.5), the map T which assigns to every $q \in Q$ the set of solutions to the linear problem (5.25), has nonempty, acyclic sets of values. Once more, we use Corollary 4.2, obtaining a solution to problem (5.22), and the proof is complete. □

5.2. *Solvability of boundary value problems with linear conditions*

Now, we shall deal with boundary value problems of the type

$$\begin{cases} \dot{x}(t) + A(t)x(t) \in F\big(t, x(t)\big), & \text{for a.a. } t \in [0, \tau], \\ Lx = \Theta, \end{cases} \tag{5.27}$$

where

(i) $A : [0, \tau] \to \mathcal{L}(\mathbb{R}^n, \mathbb{R}^n)$ is a measurable linear operator such that $|A(t)| \leqslant \gamma(t)$, for all $t \in [0, \tau]$ and some integrable function $\gamma : [0, \tau] \to [0, \infty)$,

(ii) the associated homogeneous problem

$$\begin{cases} \dot{x}(t) + A(t)x(t) = 0, & \text{for a.a. } t \in [0, \tau], \\ Lx = 0 \end{cases}$$

has only the trivial solution,

(iii) $F : [0,\tau] \times \mathbb{R}^n \multimap \mathbb{R}^n$ is a u-Carathéodory mapping with nonempty, compact and convex values (cf. Definition 2.10),

(iv) there are two nonnegative Lebesgue-integrable functions $\delta_1, \delta_2 : [0,\tau] \to [0,\infty)$ such that

$$\big|F(t,x)\big| \leqslant \delta_1(t) + \delta_2(t)|x|, \quad \text{for a.a. } t \in [0,\tau] \text{ and all } x \in \mathbb{R}^n,$$

where $|F(t,x)| = \sup\{|y| \mid y \in F(t,x)\}$.

Applying Theorem 4.13 (cf. also Proposition 2.5) to replace condition (i) in Corollary 4.3 for (5.27), we can immediately give

PROPOSITION 5.1. *Consider problem* (5.27) *with* (i)–(iv) *above and let* $G : [0,\tau] \times \mathbb{R}^n \times \mathbb{R}^n \times [0,1] \to \mathbb{R}^n$ *be a product-measurable u-Carathéodory map* (*cf. Definition* 2.10) *such that*

$$G(t,c,c,1) \subset F(t,c), \quad \textit{for all } (t,c) \in [0,\tau] \times \mathbb{R}^n.$$

Assume, furthermore, that

(v) *there exists a* (*bounded*) *retract* Q *of* $C([0,\tau],\mathbb{R}^n)$ *such that* $Q \setminus \partial Q$ *is nonempty* (*open*) *and such that* $G(t,x,q(t),\lambda)$ *is Lipschitzian in* x *with a sufficiently small Lipschitz constant* (*see Theorem* 4.13), *for a.a.* $t \in [0,\tau]$ *and each* $(q,\lambda) \in Q \times [0,1]$,

(vi) *there exists a Lebesgue integrable function* $\alpha : [0,\tau] \to [0,\infty)$ *such that*

$$\big|G\big(t,x(t),q(t),\lambda\big)\big| \leqslant \alpha(t), \quad \textit{a.e. in } [0,\tau],$$

for any $(x,q,\lambda) \in \Gamma_T$ (*i.e. from the graph of* T), *where* T *denotes the set-valued map which assigns, to any* $(q,\lambda) \in Q \times [0,1]$, *the set of solutions of*

$$\begin{cases} \dot{x}(t) + A(t)x(t) \in G\big(t,x(t),q(t),\lambda\big), & \textit{for a.a. } t \in [0,1],\\ Lx = \Theta, \end{cases}$$

(vii) $T(Q \times \{0\}) \subset Q$ *holds and* ∂Q *is fixed point free w.r.t.* T, *for every* $(q,\lambda) \in Q \times [0,1]$.

Then problem (5.27) *has a solution.*

REMARK 5.4. Rescaling t in (5.27), the interval $[0,\tau]$ can be obviously replaced in Proposition 5.1 by any compact interval J, e.g., $J = [-m,m]$, $m \in \mathbb{N}$. Therefore, the second part of Proposition 4.5 can be still applied for obtaining an entirely bounded solution.

EXAMPLE 5.2. Consider problem (5.27). Assume that conditions (i)–(iv) are satisfied. Taking (for a product-measurable $F : [0,\tau] \times \mathbb{R}^n \multimap \mathbb{R}^n$)

$$G\big(t,q(t)\big) = F\big(t,q(t)\big), \quad \text{for } q \in Q,$$

where $Q = \{\mu \in C([0,\tau],\mathbb{R}^n) \mid \max_{t\in[0,\tau]} |\mu(t)| \leqslant D\}$ and $D > 0$ is a sufficiently big constant which will be specified below, we can see that (v) holds trivially. Furthermore, according to (iv), we get

$$\bigl|G\bigl(t,q(t)\bigr)\bigr| \leqslant \delta_1(t) + \delta_2(t)D, \quad \text{for a.a. } t \in [0,\tau], \tag{5.28}$$

i.e. (vi) holds as well with $\alpha(t) = \delta_1(t) + \delta_2(t)D$. At last, the associated linear problem

$$\begin{cases} \dot{x}(t) + A(t)x(t) \in F\bigl(t,q(t)\bigr), & \text{for a.a. } t \in [0,\tau], \\ Lx = \Theta \end{cases}$$

has, according to Theorem 4.13, for every $q \in Q$, an R_δ-set of solutions of the form

$$T(q) = \int_0^\tau H(t,s) f\bigl(s,q(s)\bigr)\,\mathrm{d}s,$$

where H is the related Green function and $f \subset F$ is a measurable selection (see again Proposition 2.5).

Therefore, in order to apply Proposition 5.1 for the solvability of (5.27), we only need to show (cf. (vii)) that $T(Q) \subset Q$ (and that ∂Q is fixed point free w.r.t. T, for every $q \in Q$, which is, however, not necessary here). Hence, in view of (5.28), we have that

$$\begin{aligned} \max_{t\in[0,\tau]} \bigl|T(q)\bigr| &= \max_{t\in[0,\tau]} \left| \int_0^\tau H(t,s) f\bigl(s,q(s)\bigr)\,\mathrm{d}s \right| \\ &\leqslant \max_{t\in[0,\tau]} \int_0^\tau \bigl|H(t,s)\bigr| \bigl(\delta_1(s) + \delta_2(s)D\bigr)\,\mathrm{d}s \\ &= \max_{t,s\in[0,\tau]} \bigl|H(t,s)\bigr| \left[\int_0^\tau \delta_1(t)\,\mathrm{d}t + D \int_0^\tau \delta_2(t)\,\mathrm{d}t \right], \end{aligned}$$

and subsequently the above requirement holds for

$$D \geqslant \frac{\max_{t,s\in[0,\tau]} |H(t,s)| \int_0^\tau \delta_1(t)\,\mathrm{d}t}{1 - \max_{t,s\in[0,\tau]} |H(t,s)| \int_0^\tau \delta_2(t)\,\mathrm{d}t},$$

provided

$$\int_0^\tau \delta_2(t)\,\mathrm{d}t < \frac{1}{\max_{t,s\in[0,\tau]} |H(t,s)|}.$$

(Observe that for D strictly bigger than the above quantity, ∂Q becomes fixed point free.)

5.3. *Existence of periodic and anti-periodic solutions*

Now, consider the following special cases of Floquet boundary value problems in a reflexive Banach space E:

$$\begin{cases} \dot{x}(t) + A(t)x(t) \in F\big(t, x(t)\big), & \text{for a.a. } t \in [0,\tau], \\ x(\tau) = Mx(0), & \text{where } M = \mathrm{id} \text{ or } M = -\,\mathrm{id}. \end{cases} \tag{5.29}$$

Besides (A1), (A2), assume still

$$A(t) \equiv A(t+\tau) \quad \text{and} \quad F(t,x) \equiv F(t+\tau, x) \text{ or } F(t,x) \equiv -F(t+\tau, -x)$$
$$\text{for some } \tau > 0, \tag{5.30}$$

and, instead of (F1), that only

$$\big\|F(t,x)\big\| \leqslant \alpha_0(t) + \alpha_1(t)\|x\| \tag{5.31}$$

holds for a u-Carathéodory map $F : [0,\tau] \times E \multimap E$, for a.a. $t \in [0,\tau]$ and every $x \in E$, where $\alpha_0, \alpha_1 \in L^1([0,\tau])$. Then one can check, as in the proof of Theorem 5.1, that the solution operator $T : Q \times [0,1] \multimap E$, where $Q = \{q \in C(\mathbb{R}, E) \mid q(t) \equiv q(t+\tau) \text{ or } q(t) \equiv -q(t+\tau)\}$, associated with the fully linearized problem

$$\begin{cases} \dot{x}(t) + A(t)x(t) \in \lambda F\big(t, q(t)\big), & \text{for a.a. } t \in [0,\tau],\ \lambda \in [0,1], \\ x(\tau) = Mx(0), & \text{where } M = \mathrm{id} \text{ or } M = -\,\mathrm{id}, \end{cases} \tag{5.32}$$

is condensing and that the set of (bounded, after τ-periodic or 2τ-periodic prolongation) solutions is convex and compact, provided an analogy of (F2) holds.

Therefore, taking $G(t,c,c,0) \equiv -A(t)c$, Corollary 4.5 can be simplified as follows.

COROLLARY 5.1. *Assume that conditions* (5.30) *and* (5.31) *hold, jointly with*

- (i) $A : [0,\tau] \to \mathcal{L}(E)$ *is strongly measurable* (*cf. Definition* 2.9) *and Bochner integrable on the interval* $[0,\tau]$.
- (ii) *The linear equation* $\dot{x}(t) + A(t)x(t) = 0$ *admits a regular exponential dichotomy. Denote by G the related principal Green's function.*
- (iii) $F : [0,\tau] \times E \multimap E$ *is a u-Carathéodory map with nonempty, compact and convex values.*

Assume, furthermore, that there exists a nonempty, bounded, closed, convex subset Q of $\{q \in C(\mathbb{R}, E) \mid q(t) \equiv q(t+\tau)$ or $q(t) \equiv -q(t+\tau)\}$ with nonempty interior $\operatorname{int} Q$ *such that*

- (iv) $\gamma(F(t,\Omega)) \leqslant g(t)h(\gamma(\Omega))$, *for a.a.* $t \in [0,\tau]$, *and each* $\Omega \subset \{q(t) \in E \mid t \in [0,\tau],\ q \in Q\}$, *where* g, h *are positive functions*, g *is measurable*, h *is nondecreasing such that*

$$L := \sup\left\{ \int_0^\tau \big\|G(t,s)\big\|_{\mathcal{L}(E)} g(s)\,\mathrm{d}s \;\middle|\; t \in [0,\tau] \right\} < \infty$$

and $gh(t)L < t$, *for each* $t \in [0, \tau]$, *with a constant* $q = 1$, *if* E *is still separable, and* $q = 2$, *in general case.*

(v) $\{0\} \subset \operatorname{int} Q$ *and the boundary* ∂Q *of* Q *is fixed point free w.r.t.* T, *for every* $(q, \lambda) \in Q \times (0, 1]$, *where* T *is the map assigning, to any* $(q, \lambda) \in Q \times [0, 1]$, *the set of solutions of the fully linearized problem* (5.32).

Then problem (5.29) *admits a solution.*

REMARK 5.5. Obviously, under the assumptions (i), (ii), (iii), (5.7), (5.30) and (F2) in Section 5.1, problem (5.29) admits a solution, provided K in (5.7) is sufficiently small.

For periodic and anti-periodic problems, Proposition 5.1 can be easily simplified as follows (cf. Remark 5.3).

COROLLARY 5.2. *Consider problem*

$$\begin{cases} \dot{x}(t) + A(t)x(t) \in F\big(t, x(t)\big), & \text{for a.a. } t \in [0, \tau], \\ x(0) = x(\tau), \end{cases}$$

where $F(t, x) \equiv F(t + \tau, x)$ *satisfies conditions* (iii) *and* (iv) *in Proposition* 5.1. *Let* $G : [0, \tau] \times \mathbb{R}^n \times \mathbb{R}^n \times [0, 1] \multimap \mathbb{R}^n$ *be a product-measurable u-Carathéodory map such that*

$$G(t, c, c, 1) \subset F(t, c), \quad \text{for all } (t, c) \in [0, \tau] \times \mathbb{R}^n.$$

Assume that A *is a piece-wise continuous* (*single-valued*) *bounded* τ*-periodic* $(n \times n)$*-matrix whose Floquet multipliers lie off the unit cycle*, *jointly with* (v)–(vii) *in Proposition* 5.1, *where* $Lx = x(0) - x(\tau)$ *and* $\Theta = 0$. *Then the inclusion* $\dot{x} + A(t)x \in F(t, x)$ *admits a* τ*-periodic solution.*

COROLLARY 5.3. *Consider problem*

$$\begin{cases} \dot{x}(t) \in F\big(t, x(t)\big), & \text{for a.a. } t \in [0, \tau], \\ x(0) = -x(\tau), \end{cases}$$

where $F(t, x) \equiv -F(t + \tau, -x)$ *satisfies conditions* (iii) *and* (iv) *in Proposition* 5.1. *Let* $G : [0, \tau] \times \mathbb{R}^n \times \mathbb{R}^n \times [0, 1] \multimap \mathbb{R}^n$ *be a product-measurable u-Carathéodory map such that*

$$G(t, c, c, 1) \subset F(t, c), \quad \text{for all } (t, c) \in [0, \tau] \times \mathbb{R}^n.$$

Assume that (v)–(vii) *in Proposition* 5.1 *hold*, *where* $Lx = x(0) + x(\tau)$ *and* $\Theta = 0$. *Then the inclusion* $\dot{x} \in F(t, x)$ *admits a* 2τ*-periodic solution.*

In the case of ODEs, Corollary 5.3 can be still improved, in view of Theorem 4.14, where $\lambda = 1$ and $\xi = 0$, as follows.

COROLLARY 5.4. *Consider problem*

$$\begin{cases} \dot{x}(t) = f\big(t, x(t)\big), & \text{for a.a. } t \in [0, \tau], \\ x(0) = -x(\tau), \end{cases}$$

where $f(t, x) \equiv -f(t + \tau, -x)$ *is a Carathéodory function. Let* $g : [0, \tau] \times \mathbb{R}^n \times \mathbb{R}^n \times [0, 1] \to \mathbb{R}^n$ *be a Carathéodory function such that*

$$g(t, c, c, 1) = f(t, c), \quad \text{for all } (t, c) \in [0, \tau] \times \mathbb{R}^n.$$

Assume that

(i) *there exists a bounded retract* Q *of* $C([0, \tau], \mathbb{R}^n)$ *such that* $Q \setminus \partial Q$ *is nonempty* (*open*) *and such that* $g(t, x, q(t), \lambda)$ *satisfies*

$$\big|g\big(t, x, q(t), \lambda\big) - g\big(t, y, q(t), \lambda\big)\big| \leqslant p(t)|x - y|, \quad x, y \in \mathbb{R}^n$$

for a.a. $t \in [0, \tau]$ *and each* $(q, \lambda) \in Q \times [0, 1]$, *where* $p : [0, \tau] \to [0, \infty)$ *is a Lebesgue integrable function with* (*see* (4.31))

$$\int_0^\tau p(t)\, \mathrm{d}t \leqslant \pi,$$

(ii) *there exists a Lebesgue integrable function* $\alpha : [0, \tau] \to [0, \infty)$ *such that*

$$\big|g\big(t, x(t), q(t), \lambda\big)\big| \leqslant \alpha(t), \quad \text{a.e. in } [0, \tau],$$

for any $(x, q, \lambda) \in \Gamma_T$, *where* T *denotes the set-valued map which assigns, to any* $(q, \lambda) \in Q \times [0, 1]$, *the set of solutions of*

$$\begin{cases} \dot{x}(t) = g\big(t, x(t), q(t), \lambda\big), & \text{for a.a. } t \in [0, \tau], \\ x(0) = -x(\tau), \end{cases}$$

(iii) $T(Q \times \{0\}) \subset Q$ *holds and* ∂Q *is fixed point free w.r.t.* T, *for every* $(q, \lambda) \in Q \times [0, 1]$.

Then the equation $\dot{x} = f(t, x)$ *admits a* 2τ*-periodic solution.*

REMARK 5.6. Since in Corollaries 5.2 and 5.3 the associated homogeneous problems (cf. (ii) at the beginning of Section 5.2) have obviously only the trivial solution, the requirement $T(Q \times \{0\}) \subset Q$ reduces to $\{0\} \subset Q$, provided $G(t, x, q, \lambda) = \lambda G(t, x, \lambda)$, $\lambda \in [0, 1]$.

REMARK 5.7. The requirement concerning a fixed point free boundary ∂Q of Q in Proposition 5.1, Corollaries 5.1, 5.2, 5.3 and 5.4 can be verified by means of bounding (Liapunov-like) functions (see [11,32–34] and cf. [22, Chapter III.8]).

EXAMPLE 5.3. Consider the anti-periodic problem

$$\begin{cases} \dot{x} \in F_1(t,x) + F_2(t,x), \\ x(a) = -x(b), \end{cases} \tag{5.33}$$

where $x = (x_1, \ldots, x_n)$, $F = F_1 + F_2 = (f_{11}, \ldots, f_{1n}) + (f_{21}, \ldots, f_{2n})$, $F_1, F_2 : [a,b] \times \mathbb{R}^n \multimap \mathbb{R}^n$ are globally upper semicontinuous multivalued functions with nonempty, convex, compact values which are bounded in $t \in [a,b]$, for every $x \in \mathbb{R}^n$, and linearly bounded in $x \in \mathbb{R}^n$, for all $t \in [a,b]$.

Assume, furthermore, that there exist positive constants R_i, $i = 1, \ldots, n$ such that

$$\bigl|f_{1i}\bigl(t, x(\pm R_i)\bigr)\bigr| > \max_{\substack{t\in[a,b]\\ x\in\overline{K}}} \bigl|f_{2i}(t,x)\bigr|, \quad i = 1, \ldots, n,\ t \in (a,b),$$

where $x(\pm R_i) = (x_1, \ldots, x_{i-1}, \pm R_i, x_{i+1}, \ldots, x_n)$, $|x_j| \leqslant R_j$ and $K = \{x \in \mathbb{R}^n \mid |x_i| < R_i, i = 1, \ldots, n\}$,

$$\begin{aligned} &\bigl[f_{1i}\bigl(a, x(\pm R_i)\bigr) + f_{2i}(a,y)\bigr] \cdot \bigl[f_{1i}\bigl(b, -x(\pm R_i)\bigr) + f_{2i}(b,z)\bigr] < 0, \\ &\quad i = 1, \ldots, n, \end{aligned}$$

where $x, y, z \in \overline{K}$,

$$F_1(t,\cdot) \text{ is Lipschitzian with a sufficiently small constant } L,$$

for every $t \in [a,b]$; in the single-valued case, when $F \in C([a,b] \times \mathbb{R}^n, \mathbb{R}^n)$, it is enough to take $L \leqslant \pi/(b-a)$ (see condition (i) in Corollary 5.4).

It can be checked (see [32]; cf. [22, Example 8.40 in Chapter III.8]) that all assumptions of Corollary 5.3 (in the single-valued case, of Corollary 5.4) are satisfied, and so problem (5.33) admits a solution.

6. Multiplicity results

6.1. *Several solutions of initial value problems*

Let us recall that in order to apply Theorem 4.3, the following main steps have to be taken:

(i) the R_δ-structure of the solution set to (4.2) must be verified,
(ii) the inclusion $\overline{T(Q)} \subset S$ or, most preferably, $\overline{T(Q)} \subset Q \cap S$ must be guaranteed, together with the retractibility of T in the sense of Definition 4.1,
(iii) $N(r|_{T(Q)} \circ T)$ must be computed.

For initial value problems, condition (i) can be easily verified, provided G is still product-measurable. In fact, since u-Carathéodory inclusions (cf. Definition 2.10) with product-measurable right-hand sides G possess (according to Theorem 4.9; cf. also Proposition 2.5), for each $q \in Q \subset C(I, \mathbb{R}^n)$, an R_δ-set of solutions $x(\cdot, x_0)$ with $x(0, x_0) = x_0$, for every $x_0 \in \mathbb{R}^n$, such a requirement can be, in Theorem 4.3 with $S := \{x \in \mathrm{AC}_{\mathrm{loc}}(I, \mathbb{R}^n) \mid$

$x(0, x_0) = x_0\}$, simply avoided. Moreover, if Q is still compact and such that $\overline{T(Q)} \subset Q \cap S$, then (see Remark 4.3) $\pi_1(Q)$ need not be abelian and finitely generated.

Thus, Theorem 4.3 simplifies, for initial value problems, as follows:

COROLLARY 6.1. *Let $G : I \times \mathbb{R}^n \times \mathbb{R}^n \multimap \mathbb{R}^n$ be a product-measurable u-Carathéodory mapping, where $I = [0, \infty)$ or $I = [0, \tau]$, $\tau \in (0, \infty)$. Assume, furthermore, that there exists a (nonempty) compact, connected subset $Q \subset C(I, \mathbb{R}^n)$ which is a neighbourhood retract of $C(I, \mathbb{R}^n)$ such that $|G(t, x(t), q(t))| \leqslant \mu(t)(|x| + 1)$ holds, for every $(t, x, q) \in I \times \mathbb{R}^n \times Q$. Let the initial value problem*

$$\begin{cases} \dot{x}(t) \in G\big(t, x(t), q(t)\big), & \textit{for a.a. } t \in I, \\ x(0) = x_0 \end{cases}$$

have, for each $q \in Q$, a nonempty set of solutions $T(q)$ such that $\overline{T(Q)} \subset Q \cap S$, where $S := \{x \in \mathrm{AC}_{\mathrm{loc}}(I, \mathbb{R}^n) \mid x(0) = x_0\}$. Then the original initial value problem

$$\begin{cases} \dot{x}(t) \in F\big(t, x(t)\big), & \textit{for a.a. } t \in I, \\ x(0) = x_0 \end{cases}$$

admits at least $N(T)$ solutions, provided $G(t, c, c) \subset F(t, c)$ holds a.e. on I, for any $c \in \mathbb{R}^n$.

EXAMPLE 6.1. Consider the scalar ($n = 1$) initial value problem with $x_0 = 0$ and $I = [0, \tau]$, $\tau > 0$. Letting

$$Q := \big\{q \in \mathrm{AC}\big([0, \tau], \mathbb{R}\big) \mid q(0) = 0 \text{ and } \delta_2 \leqslant \dot{q}(t) \leqslant \delta_1$$
$$\text{or } -\delta_1 \leqslant \dot{q}(t) \leqslant -\delta_2, \text{ for a.a. } t \in [0, \tau]\big\},$$

where $0 < \delta_2 < \delta_1$ are suitable constants, Q can be easily verified to be a disjoint (!) union of two convex, compact sets, and consequently Q is a compact ANR, i.e. also a neighbourhood retract of $C([0, \tau], \mathbb{R})$. Unfortunately, Q is disconnected which excludes the direct application of Corollary 6.1.

Nevertheless, e.g., the inclusion

$$\dot{x}(t) \in \delta \operatorname{Sgn}\big(x(t)\big), \quad \text{for a.a. } t \in [0, \tau], \ \delta > 0, \tag{6.1}$$

where

$$\operatorname{Sgn}(x) = \begin{cases} -1, & \text{for } x \in (-\infty, 0), \\ [-1, 1], & \text{for } x = 0, \\ 1, & \text{for } x \in (0, \infty), \end{cases}$$

admits obviously two classical solutions $x_1(t) = \delta t$ with $x_1(0) = 0$ and $x_2(t) = -\delta t$ with $x_2(0) = 0$, satisfying the given inclusion everywhere.

The linearized inclusion

$$\dot{x}(t) \in \delta\,\mathrm{Sgn}\big(q(t)\big), \quad \text{for a.a. } t \in [0,\tau],\ \delta > 0,$$

possesses, for each $q \in Q$, either the solution $x_1(t) = \delta t$ with $x_1(0) = 0$ or $x_2(t) = -\delta t$ with $x_2(0) = 0$, depending on $\mathrm{sgn}(q(t))$, provided $\delta_2 \leqslant \delta \leqslant \delta_1$. Observe that there are no more solutions, for each $q \in Q$. Thus, we also have $\overline{T(Q)} \subset Q \cap S$ (i.e. condition (ii)), where $S := \{x \in \mathrm{AC}_{\mathrm{loc}}(I, \mathbb{R}^n) \mid x(0) = 0\}$.

The only handicap is related to the mentioned disconnectedness of Q. However, since $T : Q \to Q$, where

$$T(q) = \begin{cases} \delta t, & \text{for } q \geqslant 0, \\ -\delta t, & \text{for } q \leqslant 0, \end{cases}$$

is obviously single-valued, the application of the multivalued Nielsen theory, in the proof of Theorem 4.3 (and subsequently of Corollary 6.1), can be replaced by the single-valued one, where $Q \in \mathrm{ANR}$ can be disconnected (see the definition of the Nielsen number at the beginning of Section 3.2). We can, therefore, conclude, on the basis of the appropriately modified Corollary 6.1, that the original inclusion (6.1) admits at least $N(T) = 2$ solutions $x(t)$ with $x(0) = 0$, as observed by the direct calculations. In fact, it must therefore have, according to Theorem 4.5, a nontrivial R_δ-set of infinitely many piece-wise linear solutions $x(t)$ with $x(0) = 0$. The computation of $N(T) = 2$ (i.e. condition (iii)) is trivial, because $Q = Q^+ \cup Q^-$, where

$$\begin{aligned} (\mathrm{AR} \ni)\ Q^+ &:= \big\{q \in \mathrm{AC}\big([0,\tau], \mathbb{R}\big) \mid q(0) = 0 \text{ and} \\ &\qquad \delta_2 \leqslant \dot{q}(t) \leqslant \delta_1,\ \text{for a.a. } t \in [0,\tau]\big\}, \\ (\mathrm{AR} \ni)\ Q^- &:= \big\{q \in \mathrm{AC}\big([0,\tau], \mathbb{R}\big) \mid q(0) = 0 \text{ and} \\ &\qquad -\delta_1 \leqslant \dot{q}(t) \leqslant -\delta_2,\ \text{for a.a. } t \in [0,\tau]\big\}, \end{aligned}$$

and so for the computation of the generalized Lefschetz numbers we have $\Lambda(T|_{Q^+}) = \Lambda(T|_{Q^-}) = 1$, where $T|_{Q^+} : Q^+ \to Q^+$ and $T|_{Q^-} : Q^- \to Q^-$.

The same is obviously true for the inclusion

$$\dot{x}(t) \in \big[\delta + f\big(t, x(t)\big)\big]\,\mathrm{Sgn}\big(x(t)\big), \quad \text{for a.a. } t \in [0,\tau],\ \delta > 0,$$

where $f : [0,\tau] \times \mathbb{R} \to \mathbb{R}$ is a Carathéodory and locally Lipschitz function in x, for a.a. $t \in [0,\tau]$, such that $\delta_2 \leqslant \delta + f(t,x) \leqslant \delta_1$, for some $0 < \delta_2 < \delta_1$, because again $T : Q \to Q$.

Of course, we could arrive at the same conclusion even without an explicit usage of the Nielsen theory arguments, just through double application (separately on Q^+ and Q^-) of Theorem 3.3 (i.e. of the Lefschetz theory arguments).

REMARK 6.1. In view of Example 6.1, it is more realistic to suppose in Corollary 6.1 that (at least, for $n = 1$) the solution operator T is single-valued and that Q can be disconnected and not necessarily compact. Naturally, the first requirement seems to be rather associated with differential equations than inclusions.

6.2. *Several periodic and bounded solutions*

Now, Theorem 4.3 will be applied to boundary value problems associated with semilinear differential inclusions.

Hence, consider the problem

$$\begin{cases} \dot{x} + A(t)x \in F(t, x), \\ Lx = \Theta. \end{cases} \tag{6.2}$$

Since the composed multivalued function $F(t, q(t))$, where $F : J \times \mathbb{R}^n \multimap \mathbb{R}^n$ is a product-measurable u-Carathéodory mapping with nonempty, compact and convex values and $q \in C(J, \mathbb{R}^n)$, is, according to Proposition 2.5, measurable, we can also employ Theorem 4.13 to the associated linearized system

$$\begin{cases} \dot{x} + A(t)x \in F\big(t, q(t)\big), \\ Lx = \Theta, \end{cases} \tag{6.3}$$

provided

$$\big|F(t, x)\big| \leqslant \mu(t)\big(|x| + 1\big), \tag{6.4}$$

where $\mu : J \to [0, \infty)$ is a suitable (locally) Lebesgue integrable bounded function.

We can immediately give

THEOREM 6.1. *Consider boundary value problem* (6.2) *on a compact interval J. Assume that $A : J \to \mathbb{R}^{n^2}$ is a single-valued continuous $(n \times n)$-matrix and $F : J \times \mathbb{R}^n \multimap \mathbb{R}^n$ is a product-measurable u-Carathéodory mapping with nonempty, compact and convex values satisfying* (6.4). *Furthermore, let $L : C(J, \mathbb{R}^n) \to \mathbb{R}^n$ be a linear operator such that the homogeneous problem*

$$\begin{cases} \dot{x} + A(t)x = 0, \\ Lx = 0 \end{cases}$$

has only the trivial solution on J. Then the original problem (6.2) *has at least $N(r|_{T(Q)} \circ T(\cdot))$ solutions* (*for the definition of the Nielsen number N, see Definition* 3.2 *in Section* 3.2), *provided there exists a closed connected subset Q of $C(J, \mathbb{R}^n)$ with a finitely generated abelian fundamental group such that*

(i) *$T(Q)$ is bounded,*
(ii) *$T(q)$ is retractible onto Q with a retraction r in the sense of Definition* 4.1,
(iii) $\overline{T(Q)} \subset \{x \in \mathrm{AC}(J, \mathbb{R}^n) \mid Lx = \Theta\}$,

where $T(q)$ denotes the set of (*existing*) *solutions to* (6.3).

REMARK 6.2. In the single-valued case, we can obviously assume the unique solvability of the associated linearized problem. Moreover, Q need not then have a finitely generated abelian fundamental group (see Remark 4.3). In the multivalued case, the latter is true, provided Q is compact and $\overline{T(Q)} \subset Q$ (see again Remark 4.3).

Before presenting a nontrivial example, it will be convenient to have the following reduction property (see [6] and cf. [22, Lemma 6.6 in Chapter III.6]).

LEMMA 6.1 (Reduction). *Let X and its closed subset Y be ANR-spaces. Assume that $f : X \to X$ is a compact map, i.e. $\overline{f(X)}$ is compact, such that $f(X) \subset Y$. Denoting by $f' : Y \to Y$ the restriction of f, we have*

(i) $\mathrm{Fix}(f') = \mathrm{Fix}(f)$,

(ii) *the Nielsen relations coincide,*

(iii) $\mathrm{ind}(C, f') = \mathrm{ind}(C, f)$, *for any Nielsen class* $C \subset \mathrm{Fix}(f)$.

Thus, $N(f') = N(f)$.

Consider the u-Carathéodory system (the functions e, f, g, h have the same regularity as in Theorem 6.1)

$$\begin{cases} \dot{x} + ax \in e(t,x,y)y^{(1/m)} + g(t,x,y), \\ \dot{y} + by \in f(t,x,y)x^{(1/n)} + h(t,x,y), \end{cases} \tag{6.5}$$

where a, b are positive numbers and m, n are odd integers with $\min(m,n) \geqslant 3$. Let suitable positive constants E_0, F_0, G, H exist such that

$$\begin{aligned} \big|e(t,x,y)\big| &\leqslant E_0, & \big|f(t,x,y)\big| &\leqslant F_0, \\ \big|g(t,x,y)\big| &\leqslant G, & \big|h(t,x,y)\big| &\leqslant H, \end{aligned}$$

hold, for a.a. $t \in (-\infty, \infty)$ and all $(x,y) \in \mathbb{R}^2$.

Furthermore, assume the existence of positive constants e_0, f_0, δ_1, δ_2 such that

$$0 < e_0 \leqslant e(t,x,y), \tag{6.6}$$

for a.a. t, all x and $|y| \geqslant \delta_2$, jointly with

$$0 < f_0 \leqslant f(t,x,y), \tag{6.7}$$

for a.a. t, $|x| \geqslant \delta_1$ and all y.

As a constraint S, consider at first the periodic boundary condition

$$\big(x(0), y(0)\big) = \big(x(\omega), y(\omega)\big). \tag{6.8}$$

More precisely, we take $S = Q = Q_1 \cap Q_2 \cap Q_3$, where

$$Q_1 = \Big\{q(t) \in C\big([0,\omega], \mathbb{R}^2\big) \mid \\ \big\|q(t)\big\| := \max\Big\{\max_{t\in[0,\omega]}\big|q_1(t)\big|, \max_{t\in[0,\omega]}\big|q_2(t)\big|\Big\} \leqslant D\Big\},$$

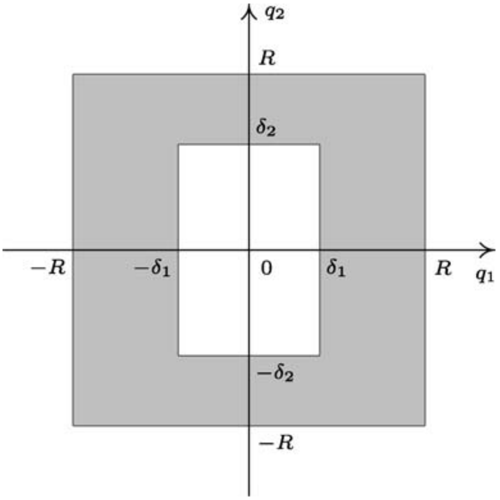

Fig. 3.

$$Q_2 = \Big\{q(t) \in C\big([0,\omega],\mathbb{R}^2\big) \mid \min_{t\in[0,\omega]}\big|q_1(t)\big| \geqslant \delta_1 > 0$$

$$\text{or } \min_{t\in[0,\omega]}\big|q_2(t)\big| \geqslant \delta_2 > 0\Big\},$$

$$Q_3 = \big\{q(t) \in C\big([0,\omega],\mathbb{R}^2\big) \mid q(0) = q(\omega)\big\},$$

the constants δ_1, δ_2, D will be specified below. For $(Q_1 \cap Q_2) \cap \mathbb{R}^2$, the situation is schematically sketched in Fig. 3.

Important properties of the set Q can be expressed as follows.

LEMMA 6.2. *The set Q defined above satisfies*:

(i) *Q is a closed connected subset of $C([0,\omega],\mathbb{R}^2)$*,
(ii) *$Q \in ANR$*,
(iii) *$\pi_1(Q) = \mathbb{Z}$*.

PROOF. Since Q is an intersection of closed sets Q_1, Q_2, Q_3, we conclude that Q is a closed subset of $C([0,\omega],\mathbb{R}^2)$ as well. The connectedness follows from the proof of (iii) below.

For (ii), it is enough to realize (see [69, Corollary 4.4 on p. 284]) that Q is the union of four closed, convex sets in the Banach space $C([0,\omega],\mathbb{R}^2)$, namely $Q = (Q_1 \cap Q_{21} \cap Q_3) \cup (Q_1 \cap Q_{22} \cap Q_3) \cup (Q_1 \cap Q_{23} \cap Q_3) \cup (Q_1 \cap Q_{24} \cap Q_3)$, where

$$Q_{21} = \Big\{q(t) \in C\big([0,\omega],\mathbb{R}^2\big) \mid \min_{t\in[0,\omega]} q_1(t) \geqslant \delta_1 > 0\Big\},$$

$$Q_{22} = \Big\{q(t) \in C\big([0,\omega],\mathbb{R}^2\big) \mid \min_{t\in[0,\omega]} q_2(t) \geqslant \delta_2 > 0\Big\},$$

$$Q_{23} = \Big\{ q(t) \in C\big([0,\omega],\mathbb{R}^2\big) \;\Big|\; \min_{t\in[0,\omega]} q_1(t) \leqslant -\delta_1 < 0 \Big\},$$

$$Q_{24} = \Big\{ q(t) \in C\big([0,\omega],\mathbb{R}^2\big) \;\Big|\; \min_{t\in[0,\omega]} q_2(t) \leqslant -\delta_2 < 0 \Big\}.$$

At last, we will show (iii). It is obvious that $\pi_1(A) = \mathbb{Z}$, where

$$A = \big\{ (x,y) \in \mathbb{R}^2 \;\big|\; \max\big(|x|,|y|\big) \leqslant D \text{ and } \big[|x| \geqslant \delta_1 \text{ or } |y| \geqslant \delta_2\big]\big\}.$$

At the same time, $A = Q \cap \mathbb{R}^2$, when regarding $\mathbb{R}^2$ as a subspace of constant functions of Q_3. For (iii), it is sufficient to show that A is a deformation retract of Q.

We define $\rho : Q \times [0,1] \to A$ by the formula

$$\rho(q,\lambda) = \big(\lambda q_1 + (1-\lambda)\overline{q_1}, \lambda q_2 + (1-\lambda)\overline{q_2}\big),$$

where $q = (q_1,q_2) \in Q$ and $\overline{q_1} = q_1(0)$, $\overline{q_2} = q_2(0)$. One can readily check that ρ is a deformation retraction, which completes the proof of our lemma. □

Besides (6.5) consider still its embedding into

$$\begin{cases} \dot{x} + ax \in \big[(1-\mu)e_0 + \mu e(t,x,y)\big]y^{1/m} + \mu g(t,x,y), \\ \dot{y} + by \in \big[(1-\mu)f_0 + \mu f(t,x,y)\big]x^{1/n} + \mu h(t,x,y), \end{cases} \tag{6.9}$$

where $\mu \in [0,1]$ and observe that (6.9) reduces to (6.5), for $\mu = 1$.

The associated linearized system to (6.9) takes, for $\mu \in [0,1]$, the form

$$\begin{cases} \dot{x} + ax \in \big[(1-\mu)e_0 + \mu e\big(t,q_1(t),q_2(t)\big)\big]q_2(t)^{1/m} + \mu g\big(t,q_1(t),q_2(t)\big), \\ \dot{y} + by \in \big[(1-\mu)f_0 + \mu f\big(t,q_1(t),q_2(t)\big)\big]q_1(t)^{1/n} + \mu h\big(t,q_1(t),q_2(t)\big), \end{cases} \tag{6.10}$$

or, equivalently,

$$\begin{cases} \dot{x} + ax = \big[(1-\mu)e_0 + \mu e_t\big]q_2(t)^{1/m} + \mu g_t, \\ \dot{y} + by = \big[(1-\mu)f_0 + \mu f_t\big]q_1(t)^{1/n} + \mu h_t, \end{cases} \tag{6.11}$$

where $e_t \subset e(t,q_1(t),q_2(t))$, $f_t \subset f(t,q_1(t),q_2(t))$, $g_t \subset g(t,q_1(t),q_2(t))$, $h_t \subset h(t,q_1(t),q_2(t))$ are measurable selections. These exist, because the u-Carathéodory functions e, f, g, h are weakly superpositionally measurable (see Proposition 2.5).

It is well known that problem (6.11) $\cap$ (6.8) has, for each $q(t) \in Q$ and every fixed quadruple of selections e_t, f_t, g_t, h_t, a unique solution $X(t) = (x(t),y(t))$, namely

$$X(t) = \begin{cases} x(t) = \displaystyle\int_0^\omega G_1(t,s)\big[\big((1-\mu)e_0 + \mu e_s\big)q_2(s)^{1/m} + \mu g_s\big]\,\mathrm{d}s, \\ y(t) = \displaystyle\int_0^\omega G_2(t,s)\big[\big((1-\mu)f_0 + \mu f_s\big)q_1(s)^{1/n} + \mu h_s\big]\,\mathrm{d}s, \end{cases}$$

where

$$G_1(t,s)=\begin{cases}\dfrac{\mathrm{e}^{-a(t-s+\omega)}}{1-\mathrm{e}^{-a\omega}}, & \text{for } 0\leqslant t\leqslant s\leqslant\omega,\\[2mm] \dfrac{\mathrm{e}^{-a(t-s)}}{1-\mathrm{e}^{-a\omega}}, & \text{for } 0\leqslant s\leqslant t\leqslant\omega,\end{cases}$$

$$G_2(t,s)=\begin{cases}\dfrac{\mathrm{e}^{-b(t-s+\omega)}}{1-\mathrm{e}^{-b\omega}}, & \text{for } 0\leqslant t\leqslant s\leqslant\omega,\\[2mm] \dfrac{\mathrm{e}^{-b(t-s)}}{1-\mathrm{e}^{-b\omega}}, & \text{for } 0\leqslant s\leqslant t\leqslant\omega.\end{cases}$$

In order to verify that $\overline{T_\mu(Q)}\subset S=Q$, where $T_\mu(\cdot)$ is the solution operator to (6.10) $\cap$ (6.8), it is just sufficient to prove that $T_\mu(Q)\subset Q$, $\mu\in[0,1]$, because $S=Q$ is closed. Hence, the Nielsen number $N(T_\mu)$ is well-defined, for every $\mu\in[0,1]$, provided only product-measurability of e, f, g, h and $T_\mu(Q)\subset Q$.

Since $X(0)=X(\omega)$, i.e. $T_\mu(Q)\subset Q_3$, it remains to prove that $T_\mu(Q)\subset Q_1$ as well as $T_\mu(Q)\subset Q_2$. Let us consider the first inclusion. In view of

$$\min_{t,s\in[0,\omega]} G_1(t,s)\geqslant\frac{\mathrm{e}^{-a\omega}}{1-\mathrm{e}^{-a\omega}}>0\quad\text{and}\quad\min_{t,s\in[0,\omega]} G_2(t,s)\geqslant\frac{\mathrm{e}^{-b\omega}}{1-\mathrm{e}^{-b\omega}}>0,$$

we obtain, for the above solution $X(t)$, that

$$\begin{aligned}\max_{t\in[0,\omega]}\left|x(t)\right| &\leqslant \max_{t\in[0,\omega]}\int_0^\omega \left|G_1(t,s)\right|\left[\left[(1-\mu)e_0+\mu e_s\right]q_2(s)^{1/m}+\mu g_s\right]\mathrm{d}s\\ &\leqslant\left[(e_0+E_0)D^{1/m}+G\right]\int_0^\omega G_1(t,s)\,\mathrm{d}s\\ &=\frac{1}{a}\left[(e_0+E_0)D^{1/m}+G\right]\end{aligned}$$

and

$$\begin{aligned}\max_{t\in[0,\omega]}\left|y(t)\right| &\leqslant \max_{t\in[0,\omega]}\int_0^\omega \left|G_2(t,s)\right|\left[\left[(1-\mu)f_0+\mu f_s\right]q_1(s)^{1/n}+\mu h_s\right]\mathrm{d}s\\ &\leqslant\left[(f_0+F_0)D^{1/n}+H\right]\int_0^\omega G_2(t,s)\,\mathrm{d}s\\ &=\frac{1}{b}\left[(f_0+F_0)D^{1/n}+H\right].\end{aligned}$$

Because of

$$\left\|X(t)\right\|=\max\left\{\max_{t\in[0,\omega]}\left|x(t)\right|,\max_{t\in[0,\omega]}\left|y(t)\right|\right\}$$

$$\leqslant \max\left\{\frac{1}{a}\big[(e_0+E_0)D^{1/m}+G\big], \frac{1}{b}\big[(f_0+F_0)D^{1/n}+H\big]\right\},$$

a sufficiently large constant D certainly exists such that $\|X(t)\| \leqslant R$, i.e. $T_\mu(Q) \subset Q_1$, independently of $\mu \in [0,1]$ and e_t, f_t, g_t, h_t.

For the inclusion $T_\mu(Q) \subset Q_2$, we proceed quite analogously.

Assuming that $q(t) \in Q_2$, we have

$$\text{either} \quad \min_{t\in[0,\omega]}\big|q_1(t)\big| \geqslant \delta_1 > 0 \quad \text{or} \quad \min_{t\in[0,\omega]}\big|q_2(t)\big| \geqslant \delta_2 > 0.$$

Therefore, we obtain for the above solution $X(t)$ that (see (6.6))

$$\begin{aligned}\min_{t\in[0,\omega]}\big|x(t)\big| &= \min_{t\in[0,\omega]}\int_0^\omega \big|G_1(t,s)\big|\big[\big[(1-\mu)e_0+\mu e_s\big]q_2(s)^{1/m}+\mu g_s\big]\,\mathrm{d}s\\ &\geqslant \big|e_0\delta_2^{1/m}-G\big|\int_0^\omega G_1(t,s)\,\mathrm{d}s = \frac{1}{a}\big|e_0\delta_2^{1/m}-G\big| > 0,\end{aligned}$$

provided $G < e_0\delta_2^{1/m}$, for $|q_2| \geqslant \delta_2$, or (see (6.7))

$$\begin{aligned}\min_{t\in[0,\omega]}\big|y(t)\big| &= \min_{t\in[0,\omega]}\int_0^\omega \big|G_2(t,s)\big|\big[\big[(1-\mu)f_0+\mu f_s\big]q_1(s)^{1/n}+\mu h_s\big]\,\mathrm{d}s\\ &\geqslant \big|f_0\delta_1^{1/n}-H\big|\int_0^\omega G_2(t,s)\,\mathrm{d}s = \frac{1}{b}\big|f_0\delta_1^{1/n}-H\big| > 0,\end{aligned}$$

provided $H < f_0\delta_1^{1/n}$, for $|q_1| \geqslant \delta_1$.

So, in order to prove that $X(t) \in Q_2$, we need to fulfill simultaneously the following inequalities:

$$\begin{cases}(1/a)\big|e_0\delta_2^{1/m}-G\big| \geqslant \delta_1 > (H/f_0)^n\\ (1/b)\big|f_0\delta_1^{1/m}-H\big| \geqslant \delta_2 > (G/e_0)^m.\end{cases} \tag{6.12}$$

Let us observe that the "amplitudes" of the multivalued functions g, h must be sufficiently small. On the other hand, if e_0 and f_0 are sufficiently large (for fixed quantities a, b, G, H), then we can easily find δ_1, δ_2 satisfying (6.12).

After all, if there exist constants δ_1, δ_2 obeying (6.12), then we arrive at $X(t) \in Q_2$, i.e., $T_\mu(Q) \subset Q_2$, independently of $\mu \in [0,1]$ and e_t, f_t, g_t, h_t. This already means that $T_\mu(Q) \subset Q$, $\mu \in [0,1]$, as required.

Now, since all the assumptions of Theorem 6.1 are satisfied, problem (6.9) $\cap$ (6.8) possesses at least $N(T_\mu(\cdot))$ solutions belonging to Q, for every $\mu \in [0,1]$. In particular, problem (6.5) $\cap$ (6.8) has $N(T_1(\cdot))$ solutions, but according to the invariance under homotopy, $N(T_1(\cdot)) = N(T_0(\cdot))$. So, it remains to compute the Nielsen number $N(T_0(\cdot))$ for the operator $T_0 : Q \to Q$, where

$$T_0(q) = \left(e_0\int_0^\omega G_1(t,s)q_2(s)^{1/m}\,\mathrm{d}s, f_0\int_0^\omega G_2(t,s)q_1(s)^{1/n}\,\mathrm{d}s\right). \tag{6.13}$$

Hence, besides (6.13), consider still its embedding into the one-parameter family of operators

$$T^{\nu}(q) = \nu T_0(q) + (1-\nu) r \circ T_0(q), \quad \nu \in [0,1],$$

where $r(q) := (r(q_1), r(q_2))$ and

$$r(q_i) = q_i(0), \quad \text{for } i = 1, 2.$$

One can readily check that $r: Q \to Q \cap \mathbb{R}^2$ is a retraction and $T_0(\overline{q}): Q \cap \mathbb{R}^2 \to Q$ is retractible onto $Q \cap \mathbb{R}^2$ with the retraction r in the sense of Definition 4.1. Thus, $r \circ T_0(\overline{q}): Q \cap \mathbb{R}^2 \to Q \cap \mathbb{R}^2$ has a fixed point $\widehat{q} \in Q \cap \mathbb{R}^2$ if and only if $\widehat{q} = T_0(\widehat{q})$. Moreover, $r \circ T_0(q): Q \to Q \cap \mathbb{R}^2$ has evidently a fixed point $\widehat{q} = Q \cap \mathbb{R}^2$ if and only if $\widehat{q} = T_0(\widehat{q})$. So, the investigation of fixed points for $T^0(q) = r \circ T_0(q)$ turns out to be equivalent with the one for $T^0(\overline{q}): Q \cap \mathbb{R}^2 \to Q \cap \mathbb{R}^2$.

Since, in view of invariance under homotopy, we have

$$N\big(T_1(\cdot)\big) = N\big(T_0(\cdot)\big) = N\big(T^1(\cdot)\big) = N\big(T^0(\cdot)\big),$$

where

$$T^0(q) = \left(\frac{e_0 \mathrm{e}^{-a\omega}}{1 - \mathrm{e}^{-a\omega}} \int_0^{\omega} \mathrm{e}^{as} q_2(s)^{1/m}\, \mathrm{d}s, \frac{f_0 \mathrm{e}^{-b\omega}}{1 - \mathrm{e}^{-b\omega}} \int_0^{\omega} \mathrm{e}^{bs} q_1(s)^{1/n}\, \mathrm{d}s \right)$$

and

$$T^0(\overline{q}) = \left(\frac{e_0}{a} \overline{q_2}^{(1/m)}, \frac{f_0}{b} \overline{q_1}^{(1/n)} \right),$$
$$\text{for } \overline{q} = (\overline{q_1}, \overline{q_2}) = \big(q_1(0), q_2(0)\big) \in Q \cap \mathbb{R}^2,$$

it remains to estimate $N(T^0(\cdot))$. It will be useful to do it by passing to a simpler finite-dimensional analogy, namely by the direct computation of fixed points of the operator

$$T^0(\overline{q}): Q \cap \mathbb{R}^2 \to Q \cap \mathbb{R}^2,$$

belonging to different Nielsen classes.

There are two fixed points $\widehat{q}_+ = (\widehat{q}_1, \widehat{q}_2)$ and $\widehat{q}_- = (-\widehat{q}_1, -\widehat{q}_2)$ in $Q \cap \mathbb{R}^2$, where

$$\widehat{q}_1 = \left(\frac{e_0}{a}\right)^{mn/(mn-1)} \left(\frac{f_0}{b}\right)^{1/(mn-1)},$$
$$\widehat{q}_2 = \left(\frac{e_0}{a}\right)^{m/(mn-1)} \left(\frac{f_0}{b}\right)^{mn/(mn-1)}.$$

These fixed points belong to different Nielsen classes, because any path u connecting them in $Q \cap \mathbb{R}^2$ and its image $T^0(u)$ are not homotopic in the space $Q \cap \mathbb{R}^2$, as it is schematically

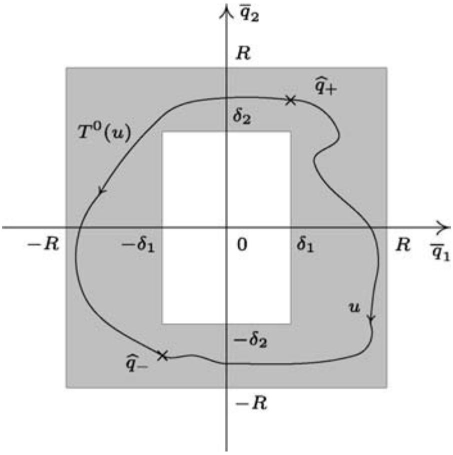

Fig. 4.

sketched in Fig. 4. Thus, according to the equivalent definition of the Nielsen number from the beginning of Section 3.2, $N(T^0(\overline{q})) = 2$. By means of the reduction property which is true here (see Lemma 6.1), we have, moreover,

$$N\bigl(T_1(\cdot)\bigr) = N\bigl(T^0(\cdot)\bigr) = N\bigl(T^0(\overline{q})\bigr) = 2$$

and so, according to Theorem 6.1, system (6.5) admits at least two solutions belonging to Q, provided suitable positive constants δ_1, δ_2 exist satisfying (6.12) and e, f, g, h are product-measurable.

In fact, system (6.5) possesses at least three solutions satisfying (6.8), when the sharp inequalities appear in (6.12), by which the lower boundary of Q becomes fixed point free. Indeed. Since

$$\Lambda\bigl(T_1(\cdot), Q\bigr) = \Lambda\bigl(T^0(\cdot), Q\bigr) = \lambda\bigl(T^0(\overline{q}), Q \cap \mathbb{R}^2\bigr)$$

holds for the generalized and ordinary Lefschetz numbers (see Section 3.1 and cf. [22, Chapter I.6]) and one can easily check that

$$\bigl|\lambda\bigl(T^0(\overline{q}), Q \cap \mathbb{R}^2\bigr)\bigr| = 2,$$

we obtain

$$\bigl|\Lambda\bigl(T_1(\cdot), Q\bigr)\bigr| = 2.$$

Furthermore, since for the self-map $T_1(\cdot)$ on the convex set $Q_1 \cap Q_3$ such that $\overline{T_1(Q_1 \cap Q_3)}$ is compact we have (see Remark 3.1)

$$\Lambda\bigl(T_1(\cdot), Q_1 \cap Q_3\bigr) = 1,$$

it follows from the additivity, contraction and existence properties of the fixed point index (see Proposition 3.2 in Section 3.3 and cf. [22, Chapter I.8]) that the mapping $T_1(\cdot)$ has the third coincidence point in $\overline{Q_1 \cap Q_3 \setminus Q}$ representing a solution of problem (6.5) $\cap$ (6.8) and belonging to $Q_1 \setminus Q$.

As we could see, problem (6.5) $\cap$ (6.8) admits at least two solutions in $Q_1 \cap Q_2$, for an arbitrary $\omega > 0$. Furthermore, because of rescaling (6.5), when replacing t by $t + (\omega/2)$, there are also two solutions of (6.5) satisfying $X(-\omega/2) = X(\omega/2)$, for an arbitrary $\omega > 0$, and belonging to $Q_1 \cap Q_2$.

Therefore, according to Proposition 4.5 and by obvious geometrical reasons, related to the appropriate subdomains of $Q_1 \cap Q_2$, system (6.5) possesses at least two entirely bounded solutions in $Q_1 \cap Q_2$.

Of course, because of replacing t by $(-t)$, the same result holds for (6.5) with negative constants a, b as well.

Finally, let us consider again system (6.5), where a, b, m, n are the same, but e, f, g, h are this time l.s.c. in (x, y), for a.a. $t \in (-\infty, \infty)$, multivalued functions with nonempty, convex, compact values and with the same estimates as above. Since each such mapping e, f, g, h has, under our regularity assumptions including the product-measurability, a Carathéodory selection (see, e.g., [22,73]), the same assertion must be also true in this new situation.

So, after summing up the above conclusions, we can give finally:

THEOREM 6.2. *Let suitable positive constants* δ_1, δ_2 *exist such that the inequalities*

$$\begin{cases} \dfrac{1}{|a|}\left|e_0\delta_2^{1/m} - G\right| \geqslant \delta_1 > \left(\dfrac{H}{f_0}\right)^n, \\ \dfrac{1}{|b|}\left|f_0\delta_2^{1/n} - H\right| \geqslant \delta_2 > \left(\dfrac{G}{e_0}\right)^m \end{cases} \tag{6.14}$$

are satisfied for constants e_0, f_0, G, H *estimating the product-measurable u-Carathéodory or l-Carathéodory multivalued functions* (*with nonempty, convex and compact values*) e, f, g, h *as above, for constants* a, b *with* $ab > 0$ *and for odd integers* m, n *with* $\min(m, n) \geqslant 3$. *Then system* (6.5) *admits at least two entirely bounded solutions. In particular, if multivalued functions* e, f, g, h *are still* ω*-periodic in* t, *then system* (6.5) *admits at least tree* ω*-periodic solutions, provided the sharp inequalities appear in* (6.14).

REMARK 6.3. Unfortunately, because of the invariance (w.r.t. the solution operator T_1) of the subdomains

$$\left\{q(t) \in C\left(\left[-\frac{\omega}{2}, \frac{\omega}{2}\right], \mathbb{R}^2\right) \,\middle|\, 0 < \delta_1 \leqslant q_1(t) \leqslant R \wedge 0 < \delta_2 \leqslant q_2(t) \leqslant R\right\}$$

and

$$\left\{q(t) \in C\left(\left[-\frac{\omega}{2}, \frac{\omega}{2}\right], \mathbb{R}^2\right) \,\middle|\, -R \leqslant q_1(t) \leqslant -\delta_1 < 0 \wedge -R \leqslant q_2(t) \leqslant -\delta_2 < 0\right\},$$

for each $\omega \in (-\infty, \infty)$, the same result can also be obtained, for example, by means of the fixed point index.

In order to avoid the handicap in Remark 6.3, let us still consider the planar system of integro-differential inclusions. For the sake of transparency, our presentation will be as simple as possible. Thus, the right-hand sides can apparently take a more general form and the multiplicity criteria in terms of inequalities can be improved.

Hence, let $x_i : [0, \omega] \to \mathbb{R}$, for $i = 1, 2$, $x = (x_1, x_2)$, $\varphi \in [0, \frac{\pi}{4}]$, $a > 0$ and consider the following system of integro-differential inclusions

$$\dot{x}_1 + a x_1 \in \sqrt[3]{p_2(x)} \cos\varphi - \sqrt[3]{p_1(x)} \sin\varphi + \varphi e, \tag{6.15}$$

$$\dot{x}_2 + a x_2 \in \sqrt[3]{p_1(x)} \cos\varphi + \sqrt[3]{p_2(x)} \sin\varphi + \varphi e, \tag{6.16}$$

where $e : [0, \omega] \times \mathbb{R}^2 \multimap \mathbb{R}$ is a product-measurable u-Carathéodory map with nonempty, convex and compact values with $|e(t, x)| \leqslant E$, for a.a. $t \in [0, \omega]$ and all $x \in \mathbb{R}^2$, and

$$p_i(x) = \frac{1}{\omega} \int_0^\omega x_i(s)\,\mathrm{d}s - B\left(\frac{1}{\omega} \int_0^\omega x_i(s)\,\mathrm{d}s - x_i\right),$$

with $B > 0$. For $\varphi = \frac{\pi}{4}$, the system takes the form

$$\dot{x}_1 + a x_1 \in \frac{\sqrt{2}}{2}\left(\sqrt[3]{p_2(x)} - \sqrt[3]{p_1(x)}\right) + \frac{\pi}{4} e, \tag{6.17}$$

$$\dot{x}_2 + a x_2 \in \frac{\sqrt{2}}{2}\left(\sqrt[3]{p_1(x)} + \sqrt[3]{p_2(x)}\right) + \frac{\pi}{4} e, \tag{6.18}$$

while, for $\varphi = 0$, it reduces to

$$\dot{x}_1 + a x_1 = \sqrt[3]{p_2(x)}, \qquad \dot{x}_2 + a x_2 = \sqrt[3]{p_1(x)}.$$

We shall be again looking for the lower estimate of the number of ω-periodic solutions to (6.17), (6.18).

Let us define sets $S = Q \subset C([0, \omega], \mathbb{R}^2)$ as follows. Function $q = (q_1, q_2)$ belongs to Q if the following conditions are satisfied:

(i) $q(0) = q(\omega)$ (ω-periodicity),

(ii) $|q(t)| \leqslant R$, for all $t \in [0, \omega]$ (boundedness),

(iii) $|q_1(t)| \geqslant \delta$ or $|q_2(t)| \geqslant \delta$, for all $t \in [0, \omega]$ (uniform boundedness of one component from below),

(iv) $q(t) = \overline{q} + \widetilde{q}(t)$, where $\overline{q} := \frac{1}{\omega} \int_0^\omega q(s)\,\mathrm{d}s$ is the integral average of q on $[0, \omega]$ (thus, $\frac{1}{\omega} \int_0^\omega \widetilde{q}(s)\,\mathrm{d}s = 0$) and $|\widetilde{q}(t)| \leqslant \varepsilon$, for all $t \in [0, \omega]$ (function q differs from its integral average by less than ε).

Values of a and ω are given, we shall specify the values of B, δ, R, E and ε in the subsequent parts.

Set Q is again a union of four closed, convex sets in the Banach space $C([0,\omega],\mathbb{R}^2)$, namely $Q = Q_1^+ \cup Q_2^+ \cup Q_1^- \cup Q_2^-$, where

$$Q_i^{\pm} = \Big\{ q(t) \in C\big([0,\omega],\mathbb{R}^2\big) \mid q \text{ satisfies (i), (ii), (iv) and} \\ \min_{t\in[0,\omega]} \pm q_i(t) \geqslant \delta > 0 \Big\}, \quad i = 1,2.$$

Thus, as in the proof of Lemma 6.2, it is a closed connected ANR-space such that $\pi_1(Q) = \mathbb{Z}$.

For homotopic parameter $\varphi = 0$, system (6.15), (6.16) reduces to a simpler case, which can be easily handled (in fact, we can explicitly compute two constant fixed points). For $\varphi = \frac{\pi}{4}$, the situation becomes non-trivial. We shall show that set Q is invariant under the solution operator, which takes a parameter $q \in Q$ to the solution x of the linearized inclusion. In this case, no obvious or easily detectable subset of Q can be recognized to be separately invariant.

In order to apply a slightly modified special case of Theorem 6.1 (cf. [18]), we use again the method of Schauder linearization. Let us take an arbitrary $q \in Q$. The system of fully linearized inclusions takes the form:

$$\dot{x}_1 + ax_1 \in \sqrt[3]{p_2(q)}\cos\varphi - \sqrt[3]{p_1(q)}\sin\varphi + \varphi e(t,q), \tag{6.19}$$

$$\dot{x}_2 + ax_2 \in \sqrt[3]{p_1(q)}\cos\varphi + \sqrt[3]{p_2(q)}\sin\varphi + \varphi e(t,q), \tag{6.20}$$

where

$$p_i(q) = \frac{1}{\omega}\int_0^{\omega} q_i(s)\,\mathrm{d}s - B\bigg(\frac{1}{\omega}\int_0^{\omega} q_i(s)\,\mathrm{d}s - q_i\bigg), \tag{6.21}$$

for $i = 1,2$.

Denoting $\overline{q} := \frac{1}{\omega}\int_0^{\omega} q(s)\,\mathrm{d}s$ the integral average of q on $[0,\omega]$, we can write $p\colon Q \subset C([0,\omega],\mathbb{R}^2) \to C([0,\omega],\mathbb{R}^2)$ in the form

$$p(q) = \overline{q} - B(\overline{q} - q). \tag{6.22}$$

For $B = 1$, operator p reduces to identity. For $B < 1$, the operator "shrinks" function q closer to its integral average. Indeed, if $q = \overline{q} + \widetilde{q}$, where $|\widetilde{q}(t)| \leqslant \varepsilon$, for all $t \in [0,\omega]$, then operator p takes q to $p(q) = \overline{q} - B\widetilde{q}$.

The fully linearized system (6.19), (6.20) possesses, for any $q \in Q$, and any Lebesgue integrable (single-valued) selection $e_0 \subset \{e(t,q)\}$, $t \in [0,\omega]$, a unique solution $x(t)$ which is given by the known convolution with the Green operator

$$x_i(t) = \int_0^{\omega} G(t,s) f_i(s)\,\mathrm{d}s, \tag{6.23}$$

where

$$f_1(s) := \sqrt[3]{p_2(q)}\cos\varphi - \sqrt[3]{p_1(q)}\sin\varphi + \varphi e_0, \tag{6.24}$$

$$f_2(s) := \sqrt[3]{p_1(q)}\cos\varphi + \sqrt[3]{p_2(q)}\sin\varphi + \varphi e_0. \tag{6.25}$$

Let us denote by T_φ the solution operator which takes $q \in Q$ to the solutions x, given by (6.23), of the linearized system (6.19), (6.20). We shall prove that Q is invariant under T_φ, namely that $T_\varphi(q) \subset Q$, for each $q \in Q$.

Let us take $q \in Q$ arbitrary. Operator p defined by (6.22) takes q to $p(q)$ such that $p(q) = \overline{q} + \widetilde{p}$, where $|\widetilde{p}(t)| \leqslant B\varepsilon$. Substituting this $p(q)$ into (6.24) and (6.25), we obtain $f_i(t) = F_i(t) + \widetilde{f}(t)$, where

$$F_1 := \sqrt[3]{\overline{q}_2}\cos\varphi - \sqrt[3]{\overline{q}_1}\sin\varphi, \qquad F_2 := \sqrt[3]{\overline{q}_1}\cos\varphi + \sqrt[3]{\overline{q}_2}\sin\varphi, \tag{6.26}$$

and $|\widetilde{f}_i(t)| \leqslant 3\sqrt[3]{B\varepsilon} + \frac{\pi E}{4}$ for all $t \in [0, \omega]$.

This estimate can be shown as follows. For $|\overline{q}_i| \geqslant 1$, one can get by direct calculation that $|\sqrt[3]{\overline{q}_i + \widetilde{p}_i} - \sqrt[3]{\overline{q}_i}| \leqslant \sqrt[3]{B\varepsilon}$, provided that $|\widetilde{p}_i| \leqslant B\varepsilon \leqslant 1$. For $|\overline{q}_i| \leqslant 1$, a careful examination of function $|\sqrt[3]{\overline{q}_i + \widetilde{p}_i} - \sqrt[3]{\overline{q}_i}|$ reveals that it is bounded from above by the value $2^{2/3}\sqrt[3]{B\varepsilon}$, provided again $|\widetilde{p}_i| \leqslant B\varepsilon \leqslant 1$. Altogether, f_i differs from F_i not more than by

$$2\frac{\sqrt{2}}{2}2^{2/3}\sqrt[3]{B\varepsilon} + \frac{\pi E}{4} \leqslant 3\sqrt[3]{B\varepsilon} + \frac{\pi E}{4},$$

as claimed.

The Green's function G in (6.23) takes the form

$$G(t,s) = \begin{cases} \dfrac{1}{1 - \mathrm{e}^{-a\omega}}\mathrm{e}^{-at}\mathrm{e}^{as}, & \text{for } 0 \leqslant s \leqslant t, \\ \dfrac{1}{1 - \mathrm{e}^{-a\omega}}\mathrm{e}^{-at}\mathrm{e}^{-a\omega}\mathrm{e}^{as}, & \text{for } t \leqslant s \leqslant \omega. \end{cases} \tag{6.27}$$

Substituting (6.26) and (6.27) into (6.23), we obtain $x_i(t) = \frac{F_i}{a} + \widetilde{x}_i(t)$, where $\widetilde{x}_i$ satisfies the inequality

$$\left|\widetilde{x}_i(t)\right| \leqslant \frac{3\sqrt[3]{B\varepsilon} + \frac{\pi}{4}E}{a},$$

for all $t \in [0, \omega]$. We can now take B and E small enough to fulfill

$$\frac{\sqrt{2}(3\sqrt[3]{B\varepsilon} + \frac{\pi}{4}E)}{a} \leqslant \frac{\varepsilon}{2}, \tag{6.28}$$

for example

$$B \leqslant \left(\frac{a}{12}\right)^3 \frac{\varepsilon^2}{\sqrt{2}} \quad \text{and} \quad E \leqslant \frac{a\varepsilon}{\pi\sqrt{2}}.$$

This means that function x differs from a constant function by less than $\frac{\varepsilon}{2}$, which implies that it differs from its integral average by less than ε. The above calculations ensure that the solution x satisfies condition (iv) of the definition of the parameter set Q, independently on $q \in Q$ and $\varphi \in [0, \frac{\pi}{4}]$. Condition (i) is trivially satisfied by the form of the Green function G.

We must further ensure that, for each $q \in Q$, function x satisfies conditions (ii) and (iii). Since both q and x differ from their integral averages by less than ε, let us first deal with constant functions. This is easy, because the solution mapping T_φ takes constant functions to functions that differ from a constant function by less than $\frac{\pi E}{4a}$ and it is a composition of

- reflection $(\overline{q}_1, \overline{q}_2) \to (\overline{q}_2, \overline{q}_1)$,
- re-scaling $(\overline{q}_1, \overline{q}_2) \to \frac{1}{a}(\sqrt[3]{\overline{q}_1}, \sqrt[3]{\overline{q}_2})$,
- rotation $(\overline{q}_1, \overline{q}_2) \to (\overline{q}_1 \cos\varphi - \overline{q}_2 \sin\varphi, \overline{q}_2 \cos\varphi + \overline{q}_1 \sin\varphi)$ by angle φ in the anticlockwise direction.

The re-scaling part of the composition ensures that constants R and δ can be specified so that the solution operator T_φ takes constant functions satisfying (ii) and (iii) to functions that again satisfy (ii) and (iii). Since functions in Q differ from their integral averages by less than ε, we need to find R, δ and ε such that the following conditions are satisfied:

$$\frac{1}{a}\sqrt[3]{R} \leqslant R - \varepsilon - \frac{\pi E}{4a} \quad \text{and} \quad \frac{\sqrt{2}}{2a}\sqrt[3]{\delta} \geqslant \delta + \sqrt{2}\varepsilon + \frac{\pi E}{4a}. \tag{6.29}$$

Inequalities (6.29) guarantee that x satisfies conditions (ii) and (iii) of the definition of the parameter set Q. Taking further $\varepsilon \leqslant \frac{\delta}{2}$ ensures that Q is a non-trivial ANR-space (leaving the "hole" inside).

Starting from $a > 0$ and $\omega > 0$, we have specified constants R, δ, B, E and ε such that set Q becomes invariant under the solution operator T_φ which takes any $q \in Q$ to the solutions x of the linearized problem (6.19), (6.20), for $\varphi \in [0, \frac{\pi}{4}]$. Moreover, observe that, for $\varphi = \frac{\pi}{4}$, there are no easily detectable subdomains of Q separately invariant under operator $T_{\pi/4}$. Figure 5 shows how operator $T_{\pi/4}$ treats constant functions in Q, for a particular choice of R and δ and helps understanding why we can not easily detect any subinvariant domains of Q.

Hence, a slightly modified special case of Theorem 6.1 (cf. [18]) ensures that system (6.15), (6.16) admits at least $N(T_{\pi/4})$ solutions. Since $T_{\pi/4}$ is compactly admissibly homotopic to T_0, we have $N(T_{\pi/4}) = N(T_0)$.

Let us further consider the retraction $r : Q \to Q$ which sends a function $q \in Q$ to its integral average $\overline{q}$. Let us define the homotopy $T^\mu : [0, 1] \times Q \to Q$ by

$$T^\mu(q) := \mu T_0(q) + (1 - \mu) r\bigl(T_0(q)\bigr).$$

This compact homotopy guarantees that $N(T^1) = N(T_0)$ equals to $N(T^0) = N(r \circ T_0)$. We can thus restrict ourselves to the computation of $N(r \circ T_0)$. Let us denote by $\overline{Q}$ the subset of Q consisting of constant functions. Since $r \circ T_0 : Q \to \overline{Q}$, all the fixed points of $r \circ T_0$ have to belong to $\overline{Q}$. Let us therefore deal with the restriction $L := r \circ T_0|_{\overline{Q}} : \overline{Q} \to \overline{Q}$, which can be explicitly written in the form

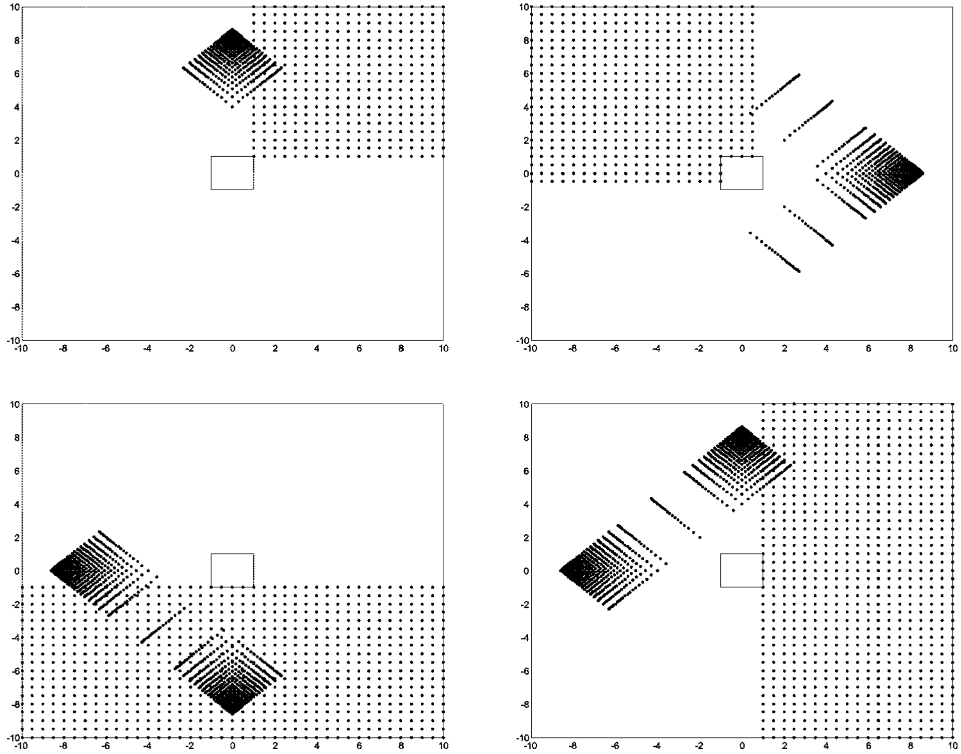

Fig. 5. Behaviour of $T_{\pi/4}$ on constant functions on Q for $R = 10$, $\delta = 1$ and $a = \frac{\sqrt{2}}{4}$. Rectangular grids of points represent constant functions $q \in Q$, the irregular grid represents their images under $T_{\pi/4}$. For simplicity, we take here $E = 0$, so that the images of constant functions become constant again. No easily detectable regions of the domain are subinvariant.

$$L(\overline{q}_1, \overline{q}_2) := \frac{1}{a}\left(\sqrt[3]{\overline{q}_2}, \sqrt[3]{\overline{q}_1}\right).$$

One can easily check by an explicit computation that L has two fixed-points in $\overline{Q}$ which belong to different Nielsen classes. Therefore, according to (reduction) Lemma 6.1, $N(L) = N(r \circ T_0) = 2$. This finally shows that system (6.17), (6.18) admits at least two ω-periodic solutions.

We are in the position to formulate the multiplicity criterion for ω-periodic solutions to system (6.17), (6.18).

THEOREM 6.3. *Let the following inequalities be satisfied*:

$$\delta < \frac{0.247}{a^{3/2}}, \quad \frac{\sqrt[3]{R}}{a} \leqslant R - \frac{5\delta}{8}, \quad E \leqslant \frac{a\delta}{2\sqrt{2}\pi}, \quad B \leqslant \left(\frac{a}{12}\right)^3 \frac{\delta^2}{4\sqrt{2}}, \tag{6.30}$$

and take $\varepsilon = \frac{\delta}{2}$. *Then system* (6.17), (6.18) *admits at least three* ω*-periodic solutions.*

PROOF. The assumptions guarantee that inequalities (6.28) and (6.29) are satisfied. Thus, two ω-periodic solutions have been already obtained by means of the Nielsen number, as above. The third can be proved quite analogously as in the proof of Theorem 6.2, by the additivity property of the fixed point index (see Proposition 3.2). □

REMARK 6.4. The inequalities in Theorem 6.3 are satisfied, e.g., for $a = \frac{\sqrt{2}}{4}$, $\delta = 1$, $R = 10$, $B \leqslant \frac{1}{2^4 3^3}$, and $E \leqslant \frac{1}{4\pi}$, as in Fig. 5, where $E = 0$.

REMARK 6.5. If the equality appears for δ in (6.30), then in the lack of periodicity, at least two entirely bounded solutions can be proved as in Theorem 6.2.

6.3. *Several anti-periodic solutions*

The following approach is via the Poincaré translation operator treated in Section 4.3. Hence, consider the system of differential inclusions

$$\dot{x} \in F(t, x), \tag{6.31}$$

where $F : \mathbb{R}^{n+1} \multimap \mathbb{R}^n$ is a u-Carathéodory mapping with nonempty, compact and convex values, satisfying (6.4). Then all solutions of (6.31) exist in the sense of Carathéodory, namely they are locally absolutely continuous and satisfy (6.31) a.e.

If $x(t, x_0) := x(t, 0, x_0)$ is a solution of (6.31) with $x(0, x_0) = x_0$, then we can define the Poincaré map (translation operator at the time $T > 0$) along the trajectories of (6.31) as follows:

$$\Phi_T : \mathbb{R}^n \multimap \mathbb{R}^n, \quad \Phi_T(x_0) := \bigl\{x(T, x_0) \mid x(t, x_0) \text{ satisfies } (6.31)\bigr\}. \tag{6.32}$$

The goal is to represent the admissible (see Theorem 4.17) map Φ_T in terms of an admissible pair (see Definition 2.5 in Section 2.2). We let $\varphi : \mathbb{R}^n \multimap C([0, T], \mathbb{R}^n)$, where

$$\varphi(X) := \bigl\{x \in C\bigl([0, T], \mathbb{R}^n\bigr) \bigm| x(0) = X \text{ and } x \text{ satisfies } (6.31)\bigr\}$$

and $C([0, T], \mathbb{R}^n)$ is the Banach space of continuous maps. According to Theorem 4.17, φ is an R_δ-mapping.

Now, we let

$$e_T : C\bigl([0, T), \mathbb{R}^n\bigr) \to \mathbb{R}^n, \quad e_T(x) = x(T),$$

where e_T is evidently continuous.

One can readily check that $\Phi_T = e_T \circ \varphi$. Moreover, $\mathcal{H} \circ \Phi_T = \mathcal{H} \circ \varphi \circ e_T$ is admissible for any homeomorphism $\mathcal{H} : \mathbb{R}^n \to \mathbb{R}^n$ (see Remark 4.15).

In fact, we have the diagram

$$\mathbb{R}^n \xleftarrow{p_\varphi} \Gamma_\varphi \xrightarrow{q_\varphi} C\bigl([0, a], \mathbb{R}^n\bigr) \xrightarrow{e_T} \mathbb{R}^n \xrightarrow{\mathcal{H}} \mathbb{R}^n,$$

where p_φ, q_φ are natural projections.

In what follows, we identify the Poincaré map Φ_T or its composition with $\mathcal{H}$, i.e. $\mathcal{H} \circ \Phi_T$, with the admissible pair $(p_\varphi, e_T \circ q_\varphi)$ or $(p_\varphi, \mathcal{H} \circ e_T \circ q_\varphi)$, i.e. we let

$$\Phi_T = (p_\varphi, e_T \circ q_\varphi) \quad \text{or} \quad \mathcal{H} \circ \Phi_T = (p_\varphi, \mathcal{H} \circ e_T \circ q_\varphi), \tag{6.33}$$

respectively.

Let $C(\mathcal{H} \circ \Phi_T)$ denote the set of coincidence points of the pair $(p_\varphi, \mathcal{H} \circ e_T \circ q_\varphi)$, while $\operatorname{Fix}(\mathcal{H} \circ \Phi_T) = \{X \in \mathbb{R}^n \mid X \in \mathcal{H}(e_T(q_\varphi(p_\varphi^{-1}(X))))\}$.

A pair for Φ_T can be easily shown to be homotopic to the identity map, so that the pair $(p_\varphi, \mathcal{H} \circ e_T \circ q_\varphi)$ is homotopic to $\mathcal{H}$ (see Theorem 4.17). We have a one-to-one correspondence between coincidence points and solutions. Since a coincidence point of $(p_\varphi, \mathcal{H} \circ e_T \circ q_\varphi)$ gives us in this way a solution $x(t)$ of (6.31) such that $x(0) = \mathcal{H}(x(T))$, the following proposition is self-evident.

PROPOSITION 6.1. *If* $\#C(p_\varphi, \mathcal{H} \circ e_T \circ q_\varphi) = \operatorname{card} C(\mathcal{H} \circ \Phi_T) \geqslant k$, *then system* (6.31) *has at least k solutions* $x_1(t), \ldots, x_k(t)$ *such that* $x_i(0) = \mathcal{H}(x_i(T))$, $i = 1, \ldots, k$.

The following lemma immediately follows from Theorem 4.17.

LEMMA 6.3. *Assume that* $Y \subset \mathbb{R}^n$ *is a compact connected ANR-space such that* $\Phi_s(Y) \subset Y$, *for every* $s \in [0, T]$ *and* $\mathcal{H}(Y) \subset Y$. *Then the pair* $(p_\varphi, \mathcal{H} \circ e_T \circ q_\varphi)$ *restricted to Y is admissibly homotopic to* $\mathcal{H}|_Y$.

As a consequence of Theorems 3.4 and 3.7 in Section 3.2, Proposition 6.1 and Lemma 6.3, we have the following

PROPOSITION 6.2. *Assume that* Φ_s, *for every* $s \in [0, T]$ *in* (6.32) *is a self-map on the torus* $\mathbb{T}^n = \mathbb{R}^n/\mathbb{Z}^n$. *Then system* (6.31) *has at least* $N(\mathcal{H})$ *solutions* $x(t)$ *such that* $x(0) = \mathcal{H}(x(T))$ *on* $\mathbb{T}^n$, *where* $N(\mathcal{H})$ *denotes the Nielsen number of a homeomorphism* $\mathcal{H}: \mathbb{T}^n \to \mathbb{T}^n$.

PROOF. The proof follows directly from Theorems 3.4 and 3.7 in Section 3.2, Proposition 6.1, Lemma 6.3 and the properties of the Nielsen number mentioned in Section 3.2. □

If in particular $\mathcal{H} = \mathrm{id}$, then according to Remark 3.6,

$$N(\mathrm{id}) = |\lambda(\mathrm{id})| = |\chi(\cdot)|$$

holds on tori, and consequently the problem considered in Proposition 6.2 should have at least $|\chi(\cdot)|$ solutions, where λ is the Lefschetz number and χ denotes the Euler–Poincaré characteristic of $\mathbb{T}^n$. Since, unfortunately, $\chi(\cdot) = 0$ for tori, this is not a suitable case for applications. In other words, we are not able to establish several T-periodic solutions in this way.

On the other hand, as the simplest application of Proposition 6.2, we can give immediately

THEOREM 6.4. *Assume that*

$$F(t,\dots,x_j+1,\dots)\equiv F(t,\dots,x_j,\dots),\quad \textit{for } j=1,\dots,n, \tag{6.34}$$

where $x=(x_1,\dots,x_n)$ *and consider system* (6.31) *on the set* $[0,\infty)\times\mathbb{T}^n$, *where* $\mathbb{T}^n=\mathbb{R}^n/\mathbb{Z}^n$. *Then system* (6.31) *admits, for every positive constant* T, *at least* $N(\mathcal{H})$ *solutions* $x(t)$ *such that*

$$x(0)=\mathcal{H}\big(x(T)\big)\pmod 1,$$

where $\mathcal{H}$ *is a continuous self-map on* $\mathbb{T}^n$ *and* $N(\mathcal{H})$ *denotes the associated Nielsen number.*

As a consequence, we obtain for $\mathcal{H}=-\mathrm{id}$ easily:

COROLLARY 6.2. *If, in addition to the assumptions of Theorem* 6.4,

$$F(t+T,-x)\equiv -F(t,x),$$

then system (6.31) *admits at least* 2^n *anti-*T*-periodic* (*or* $2T$*-periodic*) *solutions* $x(t)$ *on* $\mathbb{T}^n$, *namely* $x(t+T)\equiv -x(t)\pmod 1$.

PROOF. According to Theorem 6.4, system (6.31) admits at least $N(-\mathrm{id})$ anti-T-periodic solutions on $\mathbb{T}^n$. On $\mathbb{T}^n$, the following formula holds (see Remark 3.6), $N(-\mathrm{id})=|\lambda(-\mathrm{id})|=|\det 2I|=2^n$, which completes the proof. □

7. Remarks and comments

7.1. *Remarks and comments to general methods*

Theorems 4.1, 4.2 and Corollaries 4.1, 4.2, 4.3 are taken from [19]. Corollaries 4.1 and 4.4 generalize many single-valued situations, e.g., in [52] and [63], where the parameter set Q was only convex. Corollary 4.3 was employed for the first time in [32,33]. Corollary 4.4 generalizes the single-valued case in [39].

Theorem 4.3, for the lower estimate of the number of solutions, comes from [23]. Its slightly modified version (cf. Remark 4.3) was presented in [5]. As far as we know, there are no other general methods, using the Nielsen number, as our Theorem 4.3.

Theorem 4.4, extending Theorem 4.1 to Banach spaces, was published in [14]. Corollary 4.5 is formally new. Intuitively clear Propositions 4.4 and 4.5 (see also Remark 4.6) are contained in [22, Chapter III.1].

In view of Remark 4.6, one can check by means of the Gronwall inequality (cf. [71]) that differential inclusion $\dot{x}\in F(t,x)$ admits an entirely bounded solution $x\in AC_{\mathrm{loc}}(\mathbb{R},E)$ with $x(0)=x_0$ such that

$$\|x(t)\|\leqslant\left(\|x_0\|+\int_{-\infty}^{\infty}r(t)\,\mathrm{d}t\right)\exp\int_{-\infty}^{\infty}r(t)\,\mathrm{d}t,\qquad t\in\mathbb{R},$$

provided E is a separable or reflexive Banach space and $F: \mathbb{R} \times E \multimap E$ is a u-Carathéodory mapping (cf. Definition 2.10) such that:

(i) $\mu(F(t, B)) \leqslant k(t)\mu(B)$, for bounded subsets $B \subset E$, $t \in \mathbb{R}$, where $\mu = \alpha$ or $\mu = \gamma$, and $k \in L^1_{\mathrm{loc}}(\mathbb{R})$,

(ii) $\|y\| \leqslant r(t)(1 + \|x\|)$, for every $(t, x) \in \mathbb{R} \times E$, $y \in F(t, x)$, where $r: \mathbb{R} \to [0, \infty)$ is an integrable function such that $\int_{-\infty}^{\infty} r(t)\,\mathrm{d}t < \infty$.

Many alternative continuation principles for ODEs can be found, e.g., in [45,58,61,62, 64,65,82,83,90], and the references therein.

Theorems 4.6, 4.8, 4.9 and Proposition 4.9, dealing with the topological structure of solution sets are taken from [19]. Theorem 4.9 extends Theorem 4.5 in [57] for arbitrary (possibly infinite) intervals. In [20,21], we have developed and applied a powerful inverse limit method for the investigation of the topological structure of the solution sets. In these papers, the structure was also systematically studied for less regular right-hand sides of multivalued ODEs than those in Section 4.2.

Theorems 4.10 and 4.11 concerning the topological dimensions of solution sets come from [66]. An extension to multivalued ODEs in Banach spaces was recently published in [45]. For further results concerning the solution sets to initial value problems, see, e.g., [42,55,58,59,67,74,78,97].

Unlike for initial value problems, there are only several results concerning the topological structure of solution sets to boundary value problems. One of the most important is Theorem 4.13 in [43] which was improved by us (cf. Remark 4.10) in [21]. Theorem 4.12 comes from [20], Theorem 4.14 from [46] and Theorems 4.15, 4.16 from [7]. In [22, Chapter III.3], we collected for the first time practically all results in this field (cf. also [59, Chapter 6]). Paper [43] contains also the information about the topological dimension of the solution sets.

Theorem 4.17 about admissibility of Poincaré's operators appeared on various levels of abstraction in many papers (cf. [22, Chapter III.4 and the related comments on pp. 592–593]). For some generalizations and extensions, see [2,10,28], and the references therein.

7.2. *Remarks and comments to existence results*

Theorem 5.1 from [14] can be regarded as an infinite-dimensional extension of our earlier results in [3,4], where under suitable additional restrictions also almost-periodic solutions were detected. In [15], the methods applied to Theorem 5.1 were modified for obtaining almost-periodic solutions with values in separable Banach spaces. Theorem 5.2 is contained in [20].

Proposition 5.1, for solvability of a rather general class of boundary value problems with linear conditions, was presented for the first time in [3].

There is an enormous amount of results about the existence of periodic and anti-periodic solutions (see, e.g., [22,62,64,65,70,74,78,81,82,90]). Our Corollary 5.1 is formally new. Corollaries 5.2, 5.3, 5.4 can be found in [22, Chapter III.5]. As pointed out in Remark 5.7, the requirement concerning a fixed point free boundary of a parameter set Q were satisfied in [11,32–34] by means of bound sets. An alternative approach for satisfying this requirement can be found, e.g., in [30,31], where canonical domains or upper and lower solutions technique were applied, in the single-valued case (cf. also [65,70,81,82,90]).

7.3. *Remarks and comments to multiplicity results*

Our multiplicity results are based on the application of the Nielsen theory in Section 3.2, eventually combined with the additivity property of the fixed point index in Section 3.3. For further Nielsen theories which can be also used here, see [12,22–26,38], and the references therein. Practically all results obtained in this way were collected in [13].

Corollary 6.1 is from [5]. Variants of Theorems 6.1 and 6.2 can be found in [5,6,9], and [23], while Theorem 6.3 is a multivalued generalization of a single-valued version in [17]. Theorem 6.4 and Corollary 6.2 were presented for the first time in [24].

As pointed out in Section 1, the delicate problem of application of the Nielsen theory to differential equations is associated with the name of J. Leray.

For further multiplicity results obtained by different methods, see, e.g., [22, Chapter III.6; 62; 82, Chapter 6], and the references therein.

Acknowledgements

The collaboration and fruitful discussions with the coauthors of the quoted papers, in particular with Prof. Lech Górniewicz (Toruń), are highly appreciated. The author is also indebted to Dr. Tomáš Fürst (Olomouc) for his critical reading of the manuscript.

1. Introduction

In qualitative theory of differential equations, a prominent role is played by special classes of solutions, like periodic solutions or solutions to some kind of boundary value problem. When a system of ordinary differential equations has equilibria (i.e. constant solutions) whose stability properties are known, it becomes significant to study the connections between them by trajectories of solutions of the given system. These are called *homoclinic* or *heteroclinic* solutions (sometimes *pulses* or *kinks*) according to whether they just describe a loop based at one single equilibrium or they “start” and “end” at two distinct equilibria.

In addition to their intrinsic mathematical interest (for autonomous second order systems, for instance, homoclinics and heteroclinics act in the phase portrait as separatrices between regions where solutions behave differently; when they appear as connections between saddles they prevent structural stability, see, e.g., [38]), homoclinic and heteroclinic solutions appear in the context of a number of mathematical models for problems arising in Mechanics, Chemistry and Biology.

The study of existence of homoclinic and heteroclinic solutions has a long history. Besides phase plane analysis, whose applicability is confined to second order autonomous equations, the study of such solutions has been often made with resource to the geometric theory of ordinary differential equations and dynamical systems techniques. In the nineteenth century, Poincaré [64] already studies perturbed time periodic systems. Poincaré’s results have been the outbreak of many works. In particular, Melnikov’s theory provides instruments for the analysis of how homoclinics and heteroclinics are affected by perturbations on an Hamiltonian system. The main idea is that existence of loops or connections at some rest points can be proved by analyzing the intersection properties of the stable and unstable manifolds through those equilibrium points. In the 60’s, Melnikov [54] proves by analytical method the existence of homoclinics for non conservative perturbations, leading to chaos. Smale [81,82] then shows that in presence of a transverse homoclinic point, the Poincaré map admits a Bernouilli shift structure. Similar ideas are present in works of Birkhoff [15]. We refer to Moser [57] and Wiggins [92] for further developments.

However, starting mainly in the 80’s, a functional analytic approach added powerful tools to the research in this field. Variational methods, combining classical ideas with modern critical point theory, have thus provided a wealth of new results. A large number of contributions are devoted to this topic, the main developments being due to Ambrosetti, Bolotin, Coti Zelati, Ekeland, Rabinowitz and Séré [16,66,27,28,17,9,79,67]. The advantage of this approach comes from the fact that we can often bypass the question of transversality of the stable and unstable manifolds whose verification is delicate in practice, or obtain weaker nondegeneracy conditions. Moreover, it leads to results of a global nature. Some comparison with geometric methods and variational interpretation of Melnikov and Smale–Birkhoff theorems are studied by Ambrosetti and Badiale [7,8], see also [56,86].

This monograph is devoted mainly to the existence of heteroclinics in several types of differential equations and systems of the second and fourth orders. We divide our survey in two parts. Part 1 deals with second order equations and systems, while Part 2 concerns several important types of fourth order equations.

Part 1 starts with the analysis of classical conservative systems arising in Mechanics, like

$$u'' = \nabla V(u), \tag{1.1}$$

where $V \in C^1(\mathbb{R}^N, \mathbb{R})$ is a potential (according to the usual classical mechanics terminology, $-V$ should be called the potential) with several equilibria at the same (minimum) level. We have selected a basic set of results for this and similar problems, where V may also depend on time and be periodic in each variable. We present them with some detail. These results are due mainly to P.H. Rabinowitz and to T.O. Maxwel. Further results are mentioned without proofs. Roughly speaking, the common underlying idea is the following: suppose that V has two minima, say ξ and η; we look for heteroclinic connections between ξ and η as minimizers of the *action functional*

$$\int_{-\infty}^{+\infty} \left(\frac{|u'(t)|^2}{2} + V\bigl(u(t)\bigr) \right) \mathrm{d}t \tag{1.2}$$

in an appropriate class of functions u defined in $\mathbb{R}$ so that $u(-\infty) = \xi$ and $u(+\infty) = \eta$. Then u appears as a solution of (1.1) since this is the Euler–Lagrange equation of (1.2).

We then proceed to a different kind of problem. To state it in a simple form, we recall the Fisher–Kolmogorov type equation,

$$\frac{\partial u}{\partial t} = \frac{\partial^2 u}{\partial x^2} + g(u), \tag{1.3}$$

proposed as a model of diffusion in Biomathematics [34]. Here g is a positive, continuous function in [0, 1] such that $g(0) = g(1) = 0$. In the original model, $g(u) = u(1-u)$. A significant feature of the dynamics of (1.3) is the existence of *travelling wave fronts*, which are solutions of the form

$$u(x,t) = U(x - ct) \tag{1.4}$$

for some constant $c > 0$. The meaning of c is the speed of wave propagation. The *front profile* $U(s)$ solves then the ordinary differential equation

$$U'' + c\,U' + g(U) = 0, \tag{1.5}$$

where we look at c as a parameter. It is required that the profile satisfies $U(-\infty) = 1$, $U(+\infty) = 0$. Hence this is a problem of existence of heteroclinics for (1.5) and it is a classical one with a very rich literature. Its mathematical treatment began with Kolmogorov, Petrovski and Piskounov [45] and reached a highlight with the paper by Aronson and Weinberger [11]. However, it has continually attracted the interest of many mathematicians up to nowadays. We give an account of the most basic features of this problem dealing with more general equations than (1.5). We present a proof of the existence of a *threshold speed* c^* such that the heteroclinic exists if and only if $c \geqslant c^*$. Following an approach similar to that of Malaguti and Marcelli [48] and introducing some variational procedures like those developed in Arias, Campos, Robles-Pérez and Sanchez [10] we essentially reduce the problem to a first order ordinary differential equation and use the elementary theory of the Cauchy problem. We show that the same method is efficient in the treatment of equations in combustion theory, which differ from (1.3) in that $g(u)$ changes sign in $[0,1]$ while keeping its integral positive; in this case, it is curious that the heteroclinic appears for just one value of c.

In the second part, we consider a class of fourth order autonomous differential equations of the form

$$u'''' - \beta u'' + u^3 - u = 0, \tag{1.6}$$

where β is a real parameter. This equation admits three equilibrium states: $-1, 0$ and $+1$ and we focus on the existence of heteroclinic solutions going from -1 to $+1$. The set of bounded solutions of (1.6) has been the object of much research in the past ten years. In an impressive series of papers [59–62], Peletier and Troy have performed a systematic study of periodic, homoclinic, heteroclinic and chaotic solutions of the model equation (1.6) for the parameter range $\beta \geqslant 0$. In Section 4 we present an overview of results obtained concerning heteroclinic solutions. These include the pioneer works of Peletier and Troy and later results of Kalies and VanderVorst [43], Kalies, Kwapisz and VanderVorst [42] and van den Berg [87]. We give a first insight of methods that can be used to track heteroclinic orbits. It is convenient for simplicity to first restrict our attention to the simple model (1.6). The existence of heteroclinics for (1.6) for any $\beta \geqslant 0$ has been first proved by Peletier and Troy using a shooting method. We briefly describe their arguments in Section 4.1.

Equation (1.6) has also a variational structure. It is an elementary fact that heteroclinic solutions of (1.6) correspond to critical points of the functional

$$\mathcal{F}_\beta(u) := \int_{-\infty}^{+\infty} \left(\frac{1}{2}\left(u''^2 + \beta u'^2\right) + \frac{1}{4}\left(u^2 - 1\right)^2 \right) \mathrm{d}x$$

in an appropriate functional space. The existence of heteroclinics via variational arguments was first investigated by Peletier, Troy and VanderVorst [58] and Kalies and VanderVorst [43]. For $\beta \geqslant 0$, $\mathcal{F}_\beta$ is a positive functional. It is therefore natural to look for heteroclinics as minimizers of $\mathcal{F}_\beta$. Section 4.2 deals with a global minimization procedure which works fine for all $\beta \geqslant 0$.

When $0 \leqslant \beta \leqslant \sqrt{8}$, more heteroclinics are obtained via local minimization in well-chosen homotopy classes. Kalies, Kwapisz and VanderVorst [42] have defined precise types of functions that describe the complex structure of those solutions. In Section 4.3, we describe these homotopy classes and the profiles of the corresponding minimizers.

Many of the arguments used in the minimization process (both in the whole space and in homotopy classes) rely on the positivity of the Lagrangian

$$L\left(u, u', u''\right) = \frac{1}{2}\left(u''^2 + \beta u'^2\right) + \frac{1}{4}\left(u^2 - 1\right)^2$$

and therefore on the positivity of the parameter β. A first attempt to consider changing sign Lagrangian is made in [20,37]. The authors consider the more general functional

$$\mathcal{F}_g(u) := \int_{-\infty}^{+\infty} \left(\frac{1}{2}\left(u''^2 + g(u)u'^2\right) + f(u) \right) \mathrm{d}x \tag{1.7}$$

whose Euler–Lagrange equation is given by

$$u'''' - g(u)u'' - \frac{1}{2}g'(u)u'^2 + f'(u) = 0. \tag{1.8}$$

Here f is assumed to be a double-well potential with bottoms at ± 1 and g is neither necessarily constant nor positive. The main idea of [37] is to impose a condition on g to ensure a lower bound on the action $\mathcal{F}_g(u)$. In Section 5.1 and Section 5.2, we use the ideas of [19,20,37] to prove the existence of a global minimizer of $\mathcal{F}_g$ under convenient assumptions.

In Section 6, we discuss the case of an equation similar to (1.8) where f is a triple-well potential and address the following question. Does the dynamics possess a heteroclinic orbit connecting the extremal equilibria? Let us take a look at a classical mechanics analogy. Consider a moving particle in a potential characterized by three hills of equal height. To fix the ideas, suppose the tops of the peaks are located at -1, 0 and $+1$ and consider a motion starting from -1 at time $t \to -\infty$. As the potential energy is identical at the top of each hill, the law of energy conservation implies that the particle needs an infinite amount of time to reach the top of the second hill and therefore cannot pass through the middle-equilibrium. For the fourth order equation (1.8), the energy reads

$$E\left(u, u', u'', u'''\right) = u'''u' - \frac{1}{2}u''^2 + \frac{g(u)}{2}u'^2 + f(u).$$

For this equation of motion, a particle does not need to come at rest at the top of the second hill as the constant of motion can be satisfied with a non-zero u' due to the presence of the new terms $u'''u' - \frac{1}{2}u''^2$. In other words, the intersection of the zero energy manifold and the space $u = 0$ does not reduce to a point.

We answer positively the above question at least when the middle-equilibrium is of *saddle-focus* type. We mention that this question is relevant in the study of Ginzburg–Landau models of amphiphilic systems [36]. We refer to Section 6 for a brief description of these models.

We come back to equations with a double-well potential in Section 7. We present an existence result of multi-transition connections for Eq. (1.8). These solutions are obtained as local minimizers in classes of functions with prescribed profiles. We describe these subsets and explain briefly how the local minimization process works.

Each section is followed by some remarks and complementary results that we have chosen not to consider in details. We also give references for some extensions of results presented here in a simplified version, we refer to open questions, problems for which less is known or simply mention some related topics that did not find their way in this monograph.

Part 1. Second Order Equations and Systems

2. Second order Hamiltonian systems

2.1. *Heteroclinics for some scalar second order differential equations*

Recall that a good description of the various kinds of solutions of the mathematical pendulum equation

$$u'' + a\sin u = 0 \quad (a > 0) \tag{2.1}$$

is provided by the representation of the corresponding trajectories in the phase plane (u, u'). These are level curves of the energy, that is, they are a locus of points (u, u') of the form

$$\frac{u'^2}{2} + a(1 - \cos u) = k \tag{2.2}$$

for some constant $k \in \mathbb{R}^+$. That the energy function

$$E\bigl(u, u'\bigr) := \frac{u'^2}{2} + a(1 - \cos u)$$

is constant along solutions of (2.1) is an elementary consequence of multiplying Eq. (2.1) by u'.

When $k = 0$ in (2.2), we obtain the stable equilibria $u = 2k\pi$ $(k \in \mathbb{Z})$. If $0 < k < 2a$, the trajectories are closed curves corresponding to periodic solutions. For $k > 2a$, we obtain unbounded trajectories corresponding to solutions with periodic derivative. Finally, $k = 2a$ in (2.2) yields a locus consisting of the unstable equilibria ($u = (2k + 1)\pi$, $k \in \mathbb{Z}$) and the graphs of the functions

$$u' = \pm\sqrt{2a(1 + \cos u)}, \quad u \neq (2k + 1)\pi \text{ for all } k \in \mathbb{Z}. \tag{2.3}$$

For instance, the solutions having as trajectories the graph of this function in $]-\pi, \pi[$ have the property that

$$\lim_{t\to+\infty} u(t) = \pi, \qquad \lim_{t\to-\infty} u(t) = -\pi$$

and

$$\lim_{t\to\pm\infty} u'(t) = 0$$

or the same conditions with the roles of $+\infty$ and $-\infty$ reversed. Hence these trajectories connect two distinct (consecutive) unstable equilibria. They are called *heteroclinics* and

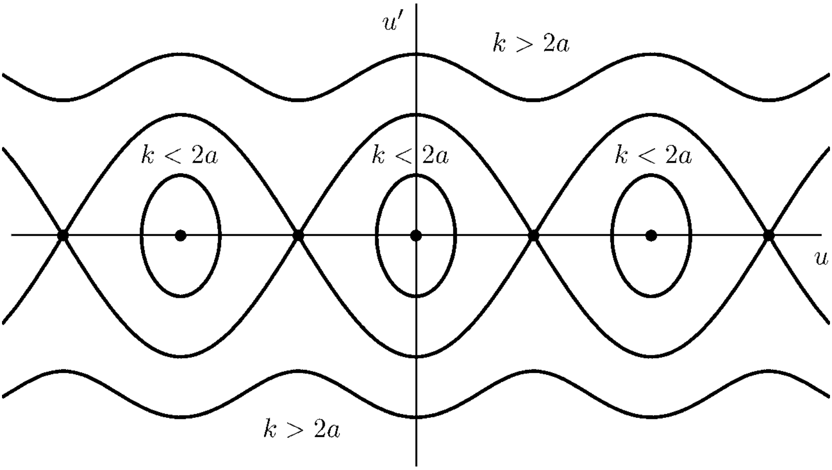

Fig. 1. The pendulum phase-plane.

any underlying solution is called a *heteroclinic solution* of (2.1). In this example it is apparent that they separate regions of the (u, u')-plane where the solutions of (2.1) have a different nature, see Fig. 1.

Of course, given the physical meaning of (2.1), it is sometimes preferable to depict trajectories not in a plane but in a cylinder (which is a plane where the points (u, u') and (v, v') are identified if and only if $u \equiv v \pmod{2\pi}$ and $u' = v'$. Then $(-\pi, 0)$ and $(\pi, 0)$ are in fact the same equilibrium and a trajectory connecting these points in the plane becomes a trajectory with equal limits at $\pm\infty$. We would then rather speak of a *homoclinic*. However, if one forgets the 2π-periodicity of the potential $a(1 - \cos u)$, or, for that matter, if one modifies it outside, say, the interval $]-\pi, \pi[$, the consideration of heteroclinics is meaningful.

Let us consider a more general autonomous scalar equation

$$u'' = f(u), \tag{2.4}$$

where $f \in C(\mathbb{R}, \mathbb{R})$ is a function such that

(A1) $f(\pm 1) = 0$;

(A2) there exists a primitive F of f such that $F(-1) = F(1) = 0$ and $F(u) > 0$ for all $u \in]-1, 1[$.

Hence Eq. (2.4) has two equilibria, $u = \pm 1$, at the (same) zero level of the potential. As for solutions of (2.4) energy is conserved, that is

$$\frac{u'^2}{2} - F(u) = K \tag{2.5}$$

for some constant K, it makes sense to look for heteroclinic solutions connecting -1 and 1, i.e. solutions such that

$$u(\pm\infty) := \lim_{x\to\pm\infty} u(x) = \pm 1 \quad \text{and} \quad u'(\pm\infty) := \lim_{x\to\pm\infty} u'(x) = 0$$

or the same properties with the roles of the $+\infty$ and $-\infty$ reversed. In fact, for such solutions we must have $K = 0$ in (2.5) and the corresponding phase plane trajectories are given explicitly by

$$u' = \pm\sqrt{2F(u)}, \quad -1 < u < 1.$$

These are equations with separable variables. With the $+$ sign, for example, integrating we obtain

$$\int_0^u \frac{\mathrm{d}v}{\sqrt{2F(v)}} = t + C, \tag{2.6}$$

for some constant C. In particular, the equilibria ± 1 are not reached in finite time whenever

$$\int_0^{\pm 1} \frac{\mathrm{d}v}{\sqrt{F(v)}}$$

diverges. This condition is obviously satisfied provided that f is locally Lipschitz. More generally, it also holds if F is at most quadratic near its minima, that is if there exists $c > 0$ so that

$$F(u) \leqslant c(u \pm 1)^2$$

in a neighborhood of -1 and $+1$, respectively.

Now we look for a heteroclinic of (2.4) from another angle. Instead of using elementary integration techniques, we show that such a solution can be characterized by a variational property. Needless to say, it may seem cumbersome to treat that simple problem in such an involved way, but since the variational method has an important role to play in the search of heteroclinics for systems and non-autonomous equations, it is worth to grasp the main ideas in an uncomplicated case.

Formally, (2.4) is the Euler–Lagrange equation of the functional

$$\mathcal{I}(u) := \int_{-\infty}^{+\infty} \left(\frac{u'^2}{2} + F(u) \right) \mathrm{d}t, \tag{2.7}$$

where $F(u)$ is the primitive of f as given in (A2). We look for the heteroclinics of (2.4) as minimizers of $\mathcal{I}$ in the functional space

$$\mathcal{E} := \left\{ u \in H^1_{\mathrm{loc}}(\mathbb{R}, \mathbb{R}) \mid u(\pm\infty) = \pm 1 \right\}.$$

In fact it will be clear that we may confine ourselves to functions taking values in $[-1,1]$ by simply assuming that F is extended by 0 on $]-\infty,-1[\cup]+1,+\infty[$. We therefore make this hypothesis from now on.

FACT 1. *Let* $\varepsilon\in]0,1[$ *and*

$$\beta_\varepsilon:=\min\left\{F(z)\mid 1-\varepsilon\leqslant z\leqslant 1-\frac{\varepsilon}{2}\ \textit{or}\ -1+\frac{\varepsilon}{2}\leqslant z\leqslant -1+\varepsilon\right\}.$$

If $u\in\mathcal{E}$ *has the property that there exist* $t_1,t_2\in\mathbb{R}$ *such that* $u(t_1)=1-\frac{\varepsilon}{2}$ *and* $u(t_2)=1-\varepsilon$ (*or* $u(t_1)=-1+\frac{\varepsilon}{2}$ *and* $u(t_2)=-1+\varepsilon$), *then we have*

$$\mathcal{I}(u)\geqslant\left|\int_{t_1}^{t_2}\left(\frac{u'^2}{2}+F(u)\right)\mathrm{d}t\right|\geqslant\frac{\varepsilon\sqrt{\beta_\varepsilon}}{\sqrt{2}}.$$

PROOF. We may assume $t_1<t_2$ and $1-\varepsilon\leqslant u(t)\leqslant 1-\frac{\varepsilon}{2}$ or $-1+\frac{\varepsilon}{2}\leqslant u(t)\leqslant -1+\varepsilon$ for $t\in[t_1,t_2]$. Using the positivity of the integrand and Schwarz's inequality we write

$$\mathcal{I}(u)\geqslant\int_{t_1}^{t_2}\left(\frac{u'^2}{2}+F(u)\right)\mathrm{d}t\geqslant\frac{\varepsilon^2}{8(t_2-t_1)}+\beta_\varepsilon(t_2-t_1)$$

and the conclusion follows from the elementary inequality $\frac{a^2}{x}+b^2x\geqslant 2ab$ which holds for all $x\geqslant 0$. □

With these preliminaries we can state and prove:

THEOREM 2.1. *If* $f\in C([-1,1],\mathbb{R})$ *satisfies the assumptions* (A1), (A2) *and is extended by* 0 *outside the interval* $]-1,1[$, *the functional* $\mathcal{I}$ *defined by* (2.7) *attains a minimum in* $\mathcal{E}$. *A minimizer is a heteroclinic solution of* (2.4) *connecting* -1 *and* 1.

PROOF. Let $(u_n)_n\subset\mathcal{E}$ be a minimizing sequence that is $\mathcal{I}(u_n)\to\inf_{\mathcal{E}}\mathcal{I}$. By passing to $v_n=\sup(-1,\inf(u_n,1))$ and observing that $\mathcal{I}(v_n)\leqslant\mathcal{I}(u_n)$, we may assume without loss of generality $-1\leqslant u_n\leqslant 1$.

For each $\varepsilon>0$, we find an interval $[s_n,t_n]$ such that $u_n(s_n)=-1+\varepsilon$, $u_n(t_n)=1-\varepsilon$ and

$$-1+\varepsilon\leqslant u_n(t)\leqslant 1-\varepsilon\quad\text{for all } t\in[s_n,t_n].$$

If u_n takes values greater than $-1+\varepsilon$ in $]-\infty,s_n]$, we may choose $s_n'<s_n$ so that $u_n(s_n')=-1+\varepsilon$ and $-1\leqslant u_n\leqslant -1+\varepsilon$ in $]-\infty,s_n']$. In the same way we find $t_n'\geqslant t_n$ so that $u_n(t_n')=1-\varepsilon$ and $1-\varepsilon\leqslant u_n\leqslant 1$ in $[t_n',+\infty[$. Define a new function

$$U_n(t)=\begin{cases}u_n(t-s_n+s_n') & \text{if } t\leqslant s_n,\\ u_n(t) & \text{if } s_n\leqslant t\leqslant t_n,\\ u_n(t+t_n'-t_n) & \text{if } t\geqslant t_n.\end{cases}$$

By the translation invariance of the integrals and the fact that the integrand is positive it is clear that

$$\mathcal{I}(U_n) \leqslant \mathcal{I}(u_n)$$

so that $(U_n)_n \subset \mathcal{E}$ is again a minimizing sequence which in addition satisfies $-1 \leqslant U_n \leqslant -1+\varepsilon$ in $]-\infty, s_n]$ and $1-\varepsilon \leqslant U_n \leqslant 1$ in $[t_n, +\infty[$. The sequence $t_n - s_n$ is bounded since

$$\mathcal{I}(U_n) \geqslant \Big(\min_{-1+\varepsilon\leqslant z\leqslant 1-\varepsilon} F(z)\Big)(s_n - t_n).$$

Observe also that as $\mathcal{I}$ is translation invariant, we may assume that $s_n = 0$.

Now, since $\sup_n \|U_n\|_{L^\infty} \leqslant 1$ and $\sup_n \|U_n'\|_{L^2}$ is bounded, we may apply the diagonal procedure to extract a subsequence that we still denote by $(U_n)_n$, and we obtain a function $u \in H^1_{\mathrm{loc}}(\mathbb{R})$ such that

$$U_n \overset{C_{\mathrm{loc}}(\mathbb{R})}{\longrightarrow} u$$

i.e. uniformly in compact intervals and

$$U_n' \overset{L^2(\mathbb{R})}{\rightharpoonup} u'.$$

In addition, we have $t_n \to \bar{t} > 0$.

Combining weak lower semicontinuity of the L^2-norm and Fatou's lemma we infer

$$\begin{aligned}\mathcal{I}(u) &\leqslant \liminf_{n\to\infty} \int_{-\infty}^{+\infty} \frac{U_n'^2}{2}\,\mathrm{d}t + \liminf_{n\to\infty}\int_{-\infty}^{+\infty} F(U_n)\,\mathrm{d}t \\ &\leqslant \lim_{n\to\infty} \mathcal{I}(U_n) = \inf_{\mathcal{E}} \mathcal{I}.\end{aligned} \tag{2.8}$$

By uniform convergence, we have $-1 \leqslant u(t) \leqslant -1+\varepsilon$ for $t \leqslant 0$ and $1-\varepsilon \leqslant u(t) \leqslant 1$ for $t > \bar{t}$. On the other hand, the fact that $\int_{-\infty}^{+\infty} F(u)\,\mathrm{d}t < +\infty$ implies that

$$\liminf_{t\to-\infty} u(t) = -1 \quad \text{and} \quad \limsup_{t\to+\infty} u(t) = 1.$$

In fact we have $\lim_{t\to\pm\infty} u(t) = \pm 1$. Otherwise there exist $\delta > 0$ and infinitely many disjoint intervals $[t_1, t_2]$ in the conditions of Fact 1 (with $\varepsilon = \delta$), implying $\mathcal{I}(u) = +\infty$ and contradicting (2.8). It follows that $u \in \mathcal{E}$ and therefore

$$\mathcal{I}(u) = \min_{\mathcal{E}} \mathcal{I}.$$

The fact that u is a solution of (2.4) follows by the usual argument that gives the Euler–Lagrange equation of a functional. For each $\varphi \in C_c^1(\mathbb{R})$, and $\tau \in \mathbb{R}$, the function $u + \tau\varphi$ belongs to $\mathcal{E}$; we compute

$$\frac{\mathrm{d}}{\mathrm{d}\tau}\bigg|_{\tau=0} \mathcal{I}(u+\tau\varphi) = \int_{-\infty}^{+\infty} \big(u'\varphi' + f(u)\varphi\big)\,\mathrm{d}t = 0$$

and, by the Du Bois–Reymond lemma, u satisfies (2.4).

Finally, since u satisfies (2.5) for some K and there exist sequences $t_n \to \pm\infty$ with $u'(t_n) \to 0$, we infer that $K = 0$ and we then conclude that $u'(\pm\infty) = 0$. $\square$

We next apply the above method to a less trivial situation: let us consider the second order non-autonomous differential equation

$$u'' = a(t)f(u), \tag{2.9}$$

where $f \in C(\mathbb{R},\mathbb{R})$ satisfies the assumptions (A1), (A2) and $a \in L^\infty(\mathbb{R},\mathbb{R})$ is such that

(A3) there exist $a_1, a_2 \in \mathbb{R}$ so that $0 < a_1 \leqslant a(t) \leqslant a_2$ for all $t \in \mathbb{R}$.

We look for a heteroclinic connection between the equilibria -1 and $+1$. In the absence of a conservation law, the variational argument appears as a natural device. So we now consider the functional

$$\mathcal{J}(u) := \int_{-\infty}^{+\infty} \left(\frac{u'^2}{2} + a(t)F(u)\right)\mathrm{d}t \tag{2.10}$$

and seek conditions that allow to minimize it in $\mathcal{E}$. If $a(t)$ is a T-periodic function then the proof of Theorem 2.1 can be easily adapted. While we cannot completely mimic the powerful modification arguments used in the autonomous case, the periodicity of a allows to localize a transition from a small neighborhood of -1 to a small one of $+1$. Indeed, keeping the notations of the proof of Theorem 2.1, the sequence of left endpoints of the intervals $[s_n, t_n]$ can be placed in the interval $[0, T]$ by time translations whose length is a multiple of T. The remaining of the proof is then similar.

If a does not possess any symmetry or periodicity property then we have to face a possible loss of compactness as the interval $[s_n, t_n]$ could escape to $+\infty$ or $-\infty$ so that the weak limit of u_n could either be one equilibrium or a homoclinic solution. The natural way to avoid such behaviours is to impose some coercivity assumption on the function a at $\pm\infty$. In some sense this penalizes transitions tending to $\pm\infty$.

Note that Fact 1 proved above has an obvious extension for this new functional: under condition (A3), it suffices to replace, in the right-hand side of the inequality, $\frac{\varepsilon\sqrt{\beta_\varepsilon}}{\sqrt{2}}$ with $\frac{\varepsilon\sqrt{a_1\beta_\varepsilon}}{\sqrt{2}}$, namely we have:

FACT 1′. *Under the assumptions of Fact* 1, *we have*

$$\mathcal{J}(u) \geqslant \left|\int_{t_1}^{t_2} \left(\frac{u'^2}{2} + a(t)F(u)\right)\mathrm{d}t\right| \geqslant \frac{\varepsilon\sqrt{a_1\beta_\varepsilon}}{\sqrt{2}}.$$

The following two facts are useful to ensure that the quasi-minimizers stay close to ±1 once they enter a sufficiently small neighborhood of ±1.

FACT 2. *Let* $\varepsilon \in \,]0,1[$ *and*

$$\mathcal{E}_{\bar t,1-\varepsilon} := \bigl\{u \in C\bigl([\bar t,+\infty[,\mathbb{R}\bigr) \bigm| u(\bar t) = 1-\varepsilon,\ u(+\infty) = 1,\ u' \in L^2\bigl([\bar t,+\infty[\bigr)\bigr\}.$$

Then, setting

$$\mathcal{J}_{[\bar t,+\infty[}(u) := \int_{\bar t}^{+\infty} \left(\frac{u'^2}{2} + a(t)F(u)\right) \mathrm{d}t,$$

there exists $v \in \mathcal{E}_{\bar t,1-\varepsilon}$ *so that* $1-\varepsilon \leqslant v(t) \leqslant 1$ *for all* $t \geqslant \bar t$ *and*

$$\mathcal{J}_{[\bar t,+\infty[}(v) \leqslant \frac{\varepsilon^2}{2} + a_2 \max_{z\in[1-\varepsilon,1]} F(z).$$

PROOF. It suffices to compute $\mathcal{J}_{[\bar t,+\infty[}(v)$ where

$$v(t) = \begin{cases} 1-\varepsilon+\varepsilon\bigl(t-\bar t\bigr), & \text{if } \bar t \leqslant t \leqslant \bar t+1,\\ 1, & \text{if } t \geqslant \bar t+1. \end{cases} \qquad \square$$

Analogously we have:

FACT 3. *Let* $\varepsilon \in \,]0,1[$ *and*

$$\mathcal{E}_{\bar t,-1+\varepsilon} := \bigl\{u \in C\bigl(]-\infty,\bar t],\mathbb{R}) \bigm| u(\bar t) = -1+\varepsilon,\ u(-\infty) = -1,\\ u' \in L^2\bigl(]-\infty,\bar t]\bigr)\bigr\}.$$

Then, setting

$$\mathcal{J}_{]-\infty,\bar t]}(u) := \int_{-\infty}^{\bar t} \left(\frac{u'^2}{2} + a(t)F(u)\right) \mathrm{d}t,$$

there exists $v \in \mathcal{E}_{\bar t,-1+\varepsilon}$ *such that* $-1 \leqslant v(t) \leqslant -1+\varepsilon$ *for all* $t \leqslant \bar t$ *and*

$$\mathcal{J}_{]-\infty,\bar t]}(v) \leqslant \frac{\varepsilon^2}{2} + a_2 \max_{z\in[-1,-1+\varepsilon]} F(z). \qquad \square$$

The family of functionals

$$\mathcal{I}_\alpha(u) := \int_{-\infty}^{+\infty} \left(\frac{u'^2}{2} + \alpha F(u)\right) \mathrm{d}t,$$

where $\alpha > 0$ is constant, is useful in what follows. According to Theorem 2.1, $\mathcal{I}_\alpha$ has a minimum in $\mathcal{E}$. Hence we may define $u_\alpha \in \mathcal{E}$ such that

$$\varphi(\alpha) := \min_{u \in \mathcal{E}} \mathcal{I}_\alpha(u) = \mathcal{I}_\alpha(u_\alpha).$$

FACT 4. *The function φ is a strictly increasing, continuous function in* $]0, +\infty[$.

PROOF. The first statement is obvious. The second is a consequence of the inequalities

$$\varphi(\alpha) + (\beta - \alpha)\int_{-\infty}^{+\infty} F(u_\beta)\,\mathrm{d}t \leqslant \varphi(\beta) \leqslant \varphi(\alpha) + (\beta - \alpha)\int_{-\infty}^{+\infty} F(u_\alpha)\,\mathrm{d}t$$

together with the fact that, when β is close to α, $\int_{-\infty}^{+\infty} F(u_\beta)\,\mathrm{d}t$ is uniformly bounded from above. □

We can now state the following theorem.

THEOREM 2.2. *Assume that $f \in C(\mathbb{R}, \mathbb{R})$, $a \in L^\infty(\mathbb{R}, \mathbb{R})$ satisfy* (A1)–(A3). *If, in addition,*

$$\lim_{|t| \to \infty} a(t) = a_2$$

and $a(t) < a_2$ in some set of nonzero measure, then (2.9) *has a heteroclinic solution from -1 to 1. This solution takes values in* $[-1, 1]$.

PROOF. Observe first that we clearly have $\inf_{\mathcal{E}} \mathcal{J} < \varphi(a_2)$ and using Fact 4, we may find $\alpha \in]0, a_2[$ so that $\inf_{\mathcal{E}} \mathcal{J} < \varphi(\alpha)$.

Fix $\bar{\varepsilon} \in]0, 1[$ and then choose $\varepsilon > 0$ sufficiently small to satisfy $\varepsilon < \bar{\varepsilon}/2$ and

$$\left(1 + \frac{a_2}{a_1}\right)\left(\frac{\varepsilon^2}{2} + a_2\mu_\varepsilon\right) < \min\left(\frac{\bar{\varepsilon}\sqrt{a_1\beta_{\bar{\varepsilon}}}}{\sqrt{2}}, \frac{\varphi(\alpha) - \inf_{\mathcal{E}} \mathcal{J}}{2}\right) \tag{2.11}$$

where $\beta_{\bar{\varepsilon}}$ is defined as in Fact 1 and

$$\mu_\varepsilon := \max_{z \in [-1, -1+\varepsilon] \cup [1-\varepsilon, 1]} F(z).$$

Let $u_n \in \mathcal{E}$ be a minimizing sequence for $\mathcal{J}$. Define the interval $[s_n, t_n]$ with respect to u_n and ε as in the proof of Theorem 2.1. According to the choice of ε, Fact 1′, Fact 2 and Fact 3 and modifying $u_n(t)$ in $]-\infty, s_n] \cup [t_n, +\infty[$ if necessary, we may assume that

$$-1 \leqslant u_n(t) \leqslant -1 + \bar{\varepsilon} \quad \text{if } t \leqslant s_n, \qquad 1 - \bar{\varepsilon} \leqslant u_n(t) \leqslant 1 \quad \text{if } t \geqslant t_n$$

and

$$\sup\bigl(\mathcal{J}_{]-\infty, s_n]}(u_n),\ \mathcal{J}_{[t_n, +\infty[}(u_n)\bigr) \leqslant \frac{\varepsilon^2}{2} + a_2\mu_\varepsilon.$$

As in the proof of Theorem 2.1, $t_n - s_n$ is bounded. We claim that s_n is bounded from above and t_n is bounded from below. Let us prove this for s_n, the proof for t_n being similar. If the claim is not true there exists $s_0 \in \mathbb{R}$ such that $a(t) \geqslant \alpha$ whenever $t \geqslant s_0$ so that $a(t) \geqslant \alpha$ whenever $t \geqslant s_n$ for large n. We then compute

$$\begin{aligned} \mathcal{J}(u_n) &\geqslant \int_{s_n}^{+\infty} \left(\frac{u_n'^2}{2} + \alpha F(u_n) \right) \mathrm{d}t \\ &\geqslant \varphi(\alpha) - \frac{a_2}{a_1} \left(\frac{\varepsilon^2}{2} + a_2 \mu_\varepsilon \right) \end{aligned}$$

and by our choice of ε in (2.11) we infer that

$$\mathcal{J}(u_n) \geqslant \frac{\varphi(\alpha) + \inf_{\mathcal{E}} \mathcal{J}}{2},$$

a contradiction with the assumption $\mathcal{J}(u_n) \to \inf_{\mathcal{E}} \mathcal{J}$.

It now follows that along some subsequence

$$u_n \overset{C_{\mathrm{loc}}(\mathbb{R})}{\longrightarrow} u, \quad u_n' \overset{L^2(\mathbb{R})}{\rightharpoonup} u', \quad s_n \to \bar{s}, \quad t_n \to \bar{t}$$

and in particular

$$-1 \leqslant u(t) \leqslant -1 + \varepsilon \quad \text{for all } t \leqslant \bar{s}, \qquad 1 - \varepsilon \leqslant u(t) \leqslant 1 \quad \text{for all } t \geqslant \bar{t}.$$

Arguing as in the proof of Theorem 2.1, it is easily shown that $u \in \mathcal{E}$, $\mathcal{J}(u) = \inf_{\mathcal{E}} \mathcal{J}$ and u is a solution of (2.9).

It remains to show that $u'(\pm\infty) = 0$. Assume, by contradiction, that there exist $\tau_n \to \infty$ and $\Delta > 0$ with $|u'(\tau_n)| \geqslant \Delta$. As from (2.9) we have $u''(\pm\infty) = 0$, we may assume that, for n sufficiently large, $|u'(t)| \geqslant \Delta/2$ for all $t \in [\tau_n, \tau_n + 1]$. But then $|u(\tau_n) - u(\tau_n + 1)| \geqslant \Delta/2$, which is impossible since $u(\pm\infty) = \pm 1$. □

2.2. *Autonomous Hamiltonian systems*

In this section we consider a basic situation for systems, adapted from the results of Rabinowitz [66]. We concentrate on the autonomous system

$$u'' = \nabla V(u), \tag{2.12}$$

where $u = (u_1, \ldots, u_N)$ and $V \in C^1(\mathbb{R}^N, \mathbb{R})$ is a non-negative potential with several isolated equilibria at minimum level. Precisely, we assume

(A4) $V \geqslant 0$, $\mathcal{M} := V^{-1}(0)$ contains at least two points and

$$\inf\bigl\{ |\xi_1 - \xi_2| \mid \xi_1, \xi_2 \in V^{-1}(0) \text{ and } \xi_1 \neq \xi_2 \bigr\} > 0;$$

(A5) for each $\varepsilon > 0$, $\inf\{V(u) \mid \operatorname{dist}(u, \mathcal{M}) \geqslant \varepsilon\} > 0$.

As in the previous section, we investigate the existence of heteroclinic connections between elements of $\mathcal{M}$. A solution $u(t)$ of (2.12) such that there exist $\xi, \eta \in \mathcal{M}$, $\xi \neq \eta$ and

$$u(-\infty) = \xi, \quad u(+\infty) = \eta, \quad u'(\pm\infty) = 0$$

is called a *heteroclinic solution of* (2.12) *from* ξ *to* η *or a heteroclinic connection between* ξ *and* η. We say also that u *starts* at ξ and *ends* at η.

Clearly, if $u(t)$ is a heteroclinic of (2.12) from ξ to η, for every $c \in \mathbb{R}$ $u(t+c)$ is also a heteroclinic from ξ to η, and $u(-t)$ is a heteroclinic from η to ξ.

Let us fix an element in $\mathcal{M}$ which we may assume without loss of generality to be 0. Then we search for heteroclinics from 0 to some $\xi \in \mathcal{M} \setminus \{0\}$. They appear as suitable minimizers of the functional

$$\mathcal{J}(u) := \int_{-\infty}^{+\infty} \left(\frac{|u'|^2}{2} + V(u) \right) \mathrm{d}t. \tag{2.13}$$

Given $\xi \in \mathcal{M} \setminus \{0\}$, it is natural to consider the class of vector functions

$$\Gamma(\xi) := \left\{ u \in H^1_{\mathrm{loc}}\left(\mathbb{R}, \mathbb{R}^N\right) \mid u(-\infty) = 0,\ u(+\infty) = \xi \right\}.$$

Let us set

$$c(\xi) := \inf_{u \in \Gamma(\xi)} \mathcal{J}(u).$$

The following fact is proved with a computation quite similar to the proof of Fact 3 in Section 2.1.

FACT 1. *Assume that* (A5) *holds. Let* $\varepsilon > 0$, *and* $z \in H^1((t_1, t_2), \mathbb{R}^N)$ *be such that*

$$\operatorname{dist}\big(u(t), \mathcal{M}\big) \geqslant \varepsilon \quad \textit{for all } t \in [t_1, t_2].$$

Then

$$\int_{t_1}^{t_2} \left(\frac{|u'|^2}{2} + V(u) \right) \mathrm{d}t \geqslant \sqrt{2\alpha_\varepsilon} \big| u(t_2) - u(t_1) \big|,$$

where $\alpha_\varepsilon := \inf\{V(u) \mid \operatorname{dist}(u, \mathcal{M} \geqslant \varepsilon)\} > 0$.

FACT 2. *Assume that* V *satisfies* (A4) *and* (A5). *Let* $u \in H^1_{\mathrm{loc}}(\mathbb{R}, \mathbb{R}^N)$ *be such that* $\mathcal{J}(u) < +\infty$. *Then* $u(-\infty)$, $u(+\infty)$ *exist and belong to* $\mathcal{M}$.

PROOF. As $\int_{-\infty}^{+\infty} V(u(t))\,\mathrm{d}t < +\infty$, we have

$$\liminf_{t \to -\infty} V\big(u(t)\big) = \liminf_{t \to +\infty} V\big(u(t)\big) = 0.$$

By assumption (A5), there exist sequences $t_n \to -\infty$, $s_n \to +\infty$ so that

$$\lim_{n\to\infty} \operatorname{dist}\bigl(u(t_n), \mathcal{M}\bigr) = \lim_{n\to\infty} \operatorname{dist}\bigl(u(s_n), \mathcal{M}\bigr) = 0.$$

Let us prove that $\lim_{t\to+\infty} u(t)$ exists (a similar argument applies at $-\infty$): if the limit does not exist we are able to find

$$0 < \varepsilon < \gamma := \frac{1}{3} \inf\bigl\{|\xi_1 - \xi_2| \mid \xi_1 \neq \xi_2 \text{ and } \xi_1, \xi_2 \in \mathcal{M}\bigr\} \tag{2.14}$$

and disjoint intervals $[\tau_n, \sigma_n]$ such that $\operatorname{dist}(u(\tau_n), \mathcal{M}) = \varepsilon, \operatorname{dist}(u(\sigma_n), \mathcal{M}) = 2\varepsilon$ and $\operatorname{dist}(u(t), \mathcal{M}) \geqslant \varepsilon$ for all $t \in [\tau_n, \sigma_n]$. But then, by virtue of Fact 1, we infer that

$$\begin{aligned}\mathcal{J}(u) &\geqslant \sum_n \int_{\tau_n}^{\sigma_n} \left(\frac{|u'|^2}{2} + V\bigl(u(t)\bigr) \right) \mathrm{d}t \\ &\geqslant \sum_n \sqrt{2\alpha_\varepsilon} \min(\varepsilon, \gamma - \varepsilon) = +\infty\end{aligned}$$

which is a contradiction. □

FACT 3. *If V has infinitely many minima, then*

$$\lim_{|\xi|\to+\infty} c(\xi) = +\infty.$$

PROOF. It suffices to prove that, given $M \geqslant 0$, there exists another number $N = N(M)$ so that $\mathcal{J}(u) \leqslant M$ and $u \in \Gamma(\xi)$ implies $|\xi| \leqslant N$. Fix $\varepsilon > 0$ as in (2.14). For u as stated, let us call $[a, b]$ a transition interval from $\xi_a \in \mathcal{M}$ to $\xi_b \in \mathcal{M}$ ($\xi_a \neq \xi_b$) if $|u(a) - \xi_a| = \varepsilon = |u(b) - \xi_b|$ and for all $t \in [a, b]$, $\operatorname{dist}(u(t), \mathcal{M}) \geqslant \varepsilon$. By definition of $\Gamma(\xi)$ we find (disjoint) transition intervals $[t_i, s_i]$, from ξ_i to η_i, $i = 1, \ldots, k$, so that $\xi_1 = 0$, $\xi_{j+1} = \eta_j$ and the $\{\xi_j\}$ are all distinct. Fact 1 implies that

$$\mathcal{J}(u) \geqslant \sum_{i=1}^{k} \sqrt{2\alpha_\varepsilon}\gamma = k\sqrt{2\alpha_\varepsilon}\gamma.$$

Hence the number k of such intervals has an upper bound, $k \leqslant M/(\sqrt{2\alpha_\varepsilon}\gamma)$. Since $u(t)$ reaches $B(\xi, \varepsilon)$, we may assume that $\eta_k = \xi$. The length of each transition interval has an upper bound that depends only on M, since

$$M \geqslant \int_{t_i}^{s_i} V\bigl(u(t)\bigr) \mathrm{d}t \geqslant \alpha_\varepsilon (s_i - t_i).$$

We then infer that

$$\bigl|u(t_i) - u(s_i)\bigr| \leqslant M\sqrt{\frac{2}{\alpha_\varepsilon}}.$$

Therefore

$$|\xi| < 2\varepsilon + 2\varepsilon(k-2) + (k-1)M\sqrt{\frac{2}{\alpha_\varepsilon}}$$

and we obtain an upper bound for $|\xi|$ depending on M. □

THEOREM 2.3. *Let* $V \in C^1(\mathbb{R}^N, \mathbb{R})$ *satisfy the assumptions* (A4) *and* (A5), *with* $0 \in \mathcal{M}$. *Then the system* (2.12) *has a heteroclinic solution starting at* 0, *and another one ending at* 0.

PROOF. By reversing time, it suffices to show that the system (2.12) possesses a heteroclinic starting at 0. By the assumption (A4) and Fact 3 (if $\mathcal{M}$ is not finite) it is clear that

$$c := \min_{\zeta \in \mathcal{M}\setminus\{0\}} c(\zeta)$$

exists, since a bounded domain intersects $\mathcal{M}$ in a finite set. Hence there exists $\xi \in \mathcal{M} \setminus \{0\}$ such that $c = c(\xi)$. Now let (u_n) be a minimizing sequence, so that

$$u_n \in \Gamma(\xi) \quad \text{and} \quad \mathcal{J}(u_n) \to c(\xi) = c.$$

By translation invariance we may assume (with ε as in (2.14))

$$\left|u_n(0)\right| = \varepsilon, \quad \left|u_n(t)\right| \leqslant \varepsilon \quad \text{for all } t \leqslant 0 \text{ and all } n \in \mathbb{N}. \tag{2.15}$$

From the boundedness of $\mathcal{J}(u_n)$ it follows immediately that $(u_n')_n$ is bounded for the L^2-norm, and the arguments of the proof of Fact 3 imply that $\|u_n\|_{L^\infty}$ is also bounded. Hence for each finite interval $[a,b]$, $\|u_n\|_{H^1(a,b)}$ is bounded and, by the diagonal procedure we may extract a subsequence, also labelled $(u_n)_n$, and find a function $u \in H^1_{\mathrm{loc}}(\mathbb{R}, \mathbb{R}^N)$ so that

$$u_n \overset{C_{\mathrm{loc}}(\mathbb{R},\mathbb{R}^N)}{\longrightarrow} u \quad \text{and} \quad u_n' \overset{L^2(\mathbb{R},\mathbb{R}^N)}{\rightharpoonup} u'.$$

The weak lower semicontinuity of the norm and Fatou's lemma imply

$$\mathcal{J}(u) \leqslant \liminf_{n\to\infty} \mathcal{J}(u_n) = c.$$

By Fact 2, $u(\pm\infty)$ exist and belong to $\mathcal{M}$. From (2.15), using local uniform convergence we have $u(-\infty) = 0$. We now prove that $u(+\infty) = \xi$. This follows from the following two claims.

CLAIM 1. $u(+\infty) \neq 0$. Suppose by contradiction that $u(+\infty) = 0$. Fix $\delta > 0$ so that $4\delta < \varepsilon$ and

$$2\delta^2 + \sup_{B_{2\delta}(0)} V < \frac{\varepsilon}{4}\sqrt{2\alpha_{\varepsilon/2}}, \tag{2.16}$$

where $\alpha_{\varepsilon/2}$ has been defined in Fact 1. There exists t_δ so that $u(t) \in B_\delta(0)$ for all $t \geqslant t_\delta$, and therefore $u_m(t_\delta) \in B_{2\delta}(0)$ for all m sufficiently large. As $|u_m(0)| = \varepsilon$, Fact 1 implies that

$$\mathcal{J}(u_m) \geqslant \frac{\varepsilon}{2}\sqrt{2\alpha_{\varepsilon/2}} + \int_{t_\delta}^{+\infty} \left(\frac{|u_m'|^2}{2} + V(u_m) \right) \mathrm{d}t. \tag{2.17}$$

Define a new function $U_m \in \Gamma(\xi)$ by

$$U_m(t) := \begin{cases} 0 & \text{if } t \leqslant t_\delta - 1, \\ (t - t_\delta + 1)u_m(t_\delta) & \text{if } t_\delta - 1 \leqslant t \leqslant t_\delta, \\ u_m(t) & \text{if } t \geqslant t_\delta. \end{cases}$$

We clearly have the estimate

$$\mathcal{J}(U_m) \leqslant \frac{1}{2}(2\delta)^2 + \sup_{B_{2\delta}(0)} V + \int_{t_\delta}^{+\infty} \left(\frac{|u_m'|^2}{2} + V(u_m) \right) \mathrm{d}t. \tag{2.18}$$

From (2.16)–(2.18) we conclude that

$$\mathcal{J}(u_m) - \mathcal{J}(U_m) \geqslant \frac{\varepsilon}{4}\sqrt{2\alpha_{\varepsilon/2}},$$

which yields a contradiction since

$$c \leqslant \limsup_{m\to\infty} \mathcal{J}(U_m) \leqslant c - \frac{\varepsilon}{4}\sqrt{2\alpha_{\varepsilon/2}} < c.$$

CLAIM 2. If $\eta \in \mathcal{M} \setminus \{0, \xi\}$, $u(+\infty) \neq \eta$. Suppose, by contradiction, that $u(+\infty) = \eta \in \mathcal{M} \setminus \{0, \xi\}$. We then fix $\delta > 0$ so that $2\delta < \varepsilon$ and

$$2\delta^2 + \sup_{B_{2\delta}(\eta)} V < \frac{\gamma}{2}\sqrt{2\alpha_\varepsilon}.$$

Let t_δ be such that $u_m(t_\delta) \in B_{2\delta}(\eta)$ for all m sufficiently large. We introduce the new function $U_m \in \Gamma(\eta)$ defined by

$$U_m(t) := \begin{cases} u_m(t) & \text{if } t \leqslant t_\delta, \\ (1 - t + t_\delta)u_m(t_\delta) + (t - t_\delta)\eta & \text{if } t_\delta \leqslant t \leqslant t_\delta + 1, \\ \eta & \text{if } t \geqslant t_\delta + 1. \end{cases}$$

As $u_m \in \Gamma(\xi)$, there exists $\underline{t}_m < \bar{t}_m$ with $t_\delta < \underline{t}_m$, so that $|u_m(\underline{t}_m) - \eta| = \varepsilon$, $\operatorname{dist}(u_m(\bar{t}_m), \mathcal{M}) = \varepsilon$ and $\operatorname{dist}(u_m(t), \mathcal{M}) \geqslant \varepsilon$ for all $t \in [\underline{t}_m, \bar{t}_m]$. Hence we have

$$\mathcal{J}(u_m) \geqslant \int_{-\infty}^{t_\delta} \left(\frac{|u_m'|^2}{2} + V(u_m) \right) \mathrm{d}t + \gamma\sqrt{2\alpha_\varepsilon}.$$

On the other hand, we infer that

$$\mathcal{J}(U_m) \leqslant 2\delta^2 + \sup_{B_{2\delta}(\eta)} V + \int_{-\infty}^{t_\delta} \left(\frac{|u_m'|^2}{2} + V(u_m) \right) \mathrm{d}t$$

and we therefore conclude that

$$\mathcal{J}(u_m) - \mathcal{J}(U_m) \geqslant \frac{\gamma}{2}\sqrt{2\alpha_\varepsilon}.$$

It now follows that

$$\limsup_{m\to\infty} \mathcal{J}(U_m) \leqslant c - \frac{\gamma}{2}\sqrt{2\alpha_\varepsilon} < c,$$

which again contradicts the definition of the level c.

Having shown that $u \in \Gamma(\xi)$, it follows that $c = \mathcal{J}(u)$ is a minimum. The usual elementary argument of the Calculus of Variations shows that u is a solution of (2.12). At last we must check that $u'(\pm\infty) = 0$. For the autonomous system , this is particularly simple. Indeed, since u is a solution of (2.12), it satisfies the energy identity

$$\frac{|u'|^2}{2} + V(u) = K$$

for some constant K, and it is easy to see that $K = 0$. □

In presence of symmetries something else can be said. Let us consider the important case where V is periodic in each coordinate. For definiteness, we assume the period is the same for all coordinates and that the minimizers of V are the translates of 0:

(A6) $V \in C^1(\mathbb{R}^N, \mathbb{R})$ is a potential periodic in each variable u_i with period 1, $\min_{\mathbb{R}^N} V = 0$ and $\mathcal{M} = V^{-1}(0) = \mathbb{Z}^N$.

Of course, the condition (A6) implies that (A4) and (A5) hold, so that Theorem 2.3 applies to this class of potentials.

THEOREM 2.4. *If* $V \in C^1(\mathbb{R}^N, \mathbb{R})$ *satisfies* (A6) *then for each* $\beta \in \mathcal{M}$ *there are at least* $2N$ *heteroclinic solutions of* (2.12) *starting from* β *and at least* $2N$ *heteroclinic solutions of* (2.12) *ending at* β.

IDEA OF THE PROOF. We may assume that $\beta = 0$ and we keep the notation introduced before. Whenever $c(\xi)$ is attained for some $\xi \in \mathcal{M} \setminus \{0\}$, the minimizer is a heteroclinic from 0 to ξ. Let G be the subgroup of $\mathbb{Z}^N$ spanned by the elements $\xi \in \mathcal{M} \setminus \{0\}$ so that $c(\xi)$ is attained. It follows from Theorem 2.3 that $G \neq 0$. If $G \neq \mathbb{Z}^N$, we can select $\zeta \in \mathbb{Z}^N \setminus G$ so that

$$c(\zeta) = \min_{\zeta' \in \mathbb{Z}^N \setminus G} c(\zeta').$$

Then we prove that $c(\zeta)$ is attained, by mimicking the proof of Theorem 2.3. The main difference is in the proof of Claim 2. When we take $\eta \in \mathcal{M} \setminus \{0, \zeta\}$ we have to allow the possibility that $\eta \in G$. But this implies that $\zeta - \eta \in \mathbb{Z}^N \setminus G$. The minimizing sequence (u_m) is then modified to a sequence in $\Gamma(\zeta - \eta)$, given by

$$U_m(t) := \begin{cases} 0 & \text{if } t \leqslant t_\delta - 1, \\ (t - t_\delta + 1)\big(u_m(t_\delta) - \eta\big) & \text{if } t_\delta - 1 \leqslant t \leqslant t_\delta, \\ u_m(t) - \eta & \text{if } t \geqslant t_\delta. \end{cases}$$

The appropriate choice of δ and the fact that $V(u_m(t) - \eta) = V(u_m(t))$ lead to the usual contradiction with the choice of ζ. Therefore we conclude that $G = \mathbb{Z}^N$. This yields N $\mathbb{Z}$-independent elements ξ so that there exist heteroclinics u form 0 to ξ. For each such ξ, $u(-t) - \xi$ is a heteroclinic from 0 to $-\xi$. □

2.3. *Periodic Hamiltonian systems: Multiplicity. Multibump solutions*

In this section we are interested in non-autonomous systems of the form

$$u'' = \nabla_u V(t, u), \tag{2.19}$$

where the potential is periodic in the time variable as well as in each spatial variable u_i ($i = 1, \ldots, N$). For simplicity, the period is supposed to be the same for all the variables. The results of the previous section carry over to this kind of systems provided the assumptions on the potential are adequately rephrased. Namely, $V(t, \cdot)$ must have equilibria at the minimum level of the potential that are independent of t.

Let us state the assumptions on V:

(A7) $V \in C^2(\mathbb{R} \times \mathbb{R}^N, \mathbb{R})$ is 1-periodic in each variable $t, u_i, i = 1, \ldots, n$;

(A8) $V(t, 0) = 0 < V(t, u)$ for all $t \in \mathbb{R},\ u \in \mathbb{R}^N \setminus \mathbb{Z}^N$.

Clearly, we may consider different given periods in each variable of V by rescaling. Note also that the assumptions (A7) and (A8) imply that $\mathcal{M} := \{u \in \mathbb{R}^N\colon\ V(t, u) = 0\} = \mathbb{Z}^N$ independently of t.

We easily recognize that Fact 1 and Fact 2 of the preceding section extend to the class of potentials we are considering by now. We only have to replace $V(u)$ by $V(t, u)$ and define

$$\alpha_\varepsilon := \inf\big\{V(t, u) \mid t \in \mathbb{R},\ \operatorname{dist}(u, \mathcal{M}) \geqslant \varepsilon\big\}. \tag{2.20}$$

As before, we make use of the functional $\mathcal{J}$ given by

$$\mathcal{J}(u) := \int_{-\infty}^{+\infty} \left(\frac{|u'|^2}{2} + V(t, u)\right) \mathrm{d}t. \tag{2.21}$$

For each given pair of elements $\xi, \eta \in \mathcal{M}$, consider the class of functions

$$\Gamma(\xi, \eta) := \big\{u \in C\big(\mathbb{R}, \mathbb{R}^N\big) \bigm| u(-\infty) = \xi,\ u(+\infty) = \eta \text{ and } u' \in L^2(\mathbb{R})\big\}.$$

Obviously, $\Gamma(\xi, \eta) \subset H^1_{\mathrm{loc}}(\mathbb{R}, \mathbb{R}^N)$. Set

$$c(\xi, \eta) := \inf_{u \in \Gamma(\xi, \eta)} \mathcal{J}(u). \tag{2.22}$$

We cannot guarantee, in general, that $c(\xi, \eta)$ is attained at a heteroclinic from ξ to η. However it is attained at a *heteroclinic chain* between ξ and η in the sense of the following statement which, according to Rabinowitz [70], was first obtained by Strobel in his Ph.D. dissertation.

THEOREM 2.5. *Assume* $V \in C^2(\mathbb{R} \times \mathbb{R}^N, \mathbb{R})$ *satisfies* (A7) *and* (A8). *For each pair* $\xi, \eta \in \mathcal{M}$ $(\xi \neq \eta)$ *there exists a finite family* $\{w_1, \dots, w_j\} \subset \mathcal{M}$ *with* $w_1 = \xi$, $w_j = \eta$, *and a corresponding family of heteroclinics* v^i *of* (2.19), *with*

$$\mathcal{J}\left(v^i\right) = c(w_i, w_{i+1}), \quad v^i \in \Gamma(w_i, w_{i+1}),\ i = 1, \dots, j-1$$

and

$$\sum_{i=1}^{j-1} \mathcal{J}\left(v^i\right) = c(\xi, \eta).$$

It is easily seen by (A7)–(A8) that the v^i's may be assumed to be *basic heteroclinics* by which we mean that none of the heteroclinic chains, with more than one element, joining w_i and w_{i+1}, achieve the value $\mathcal{J}(v^i)$.

Variational methods have proved to be fruitful in investigating the existence of multiple heteroclinics for Hamiltonian systems of the type (2.19). Different approaches have been proposed by several authors but all of them share a common feature: at the start these always require some nondegeneracy assumption, like stating that some solution of (2.19) is in a sense isolated. This kind of assumption naturally excludes autonomous systems whereas it is commonly conjectured it is generically fulfilled when V depends on t although it is quite complicate to check it on concrete examples.

We shall take advantage from the existence of a basic heteroclinic chain from ξ to η in order to describe, following [70], how true heteroclinics from ξ to η may be obtained. We shall see that we can impose these solutions to spend arbitrarily large amounts of time near the "vertices" w_i. Hence there are infinitely many such solutions. This is one of several multiplicity results where solutions are distinguished by means of their behaviour with respect to the equilibria of the system (2.19): one therefore refers to "*multibump*" solutions.

Before stating the theorem, we first introduce a nondegeneracy condition. Given $\xi \neq \eta \in \mathcal{M}$, set

$$\mathcal{S}(\xi, \eta) := \left\{q(0) \in \mathbb{R}^N \mid q \in \Gamma(\xi, \eta),\ \mathcal{J}(q) = c(\xi, \eta)\right\}.$$

As $q(0) \in \mathcal{S}(\xi, \eta)$ implies $q(k) \in \mathcal{S}(\xi, \eta)$ for any integer k, we infer that ξ and η belong to $\bar{\mathcal{S}}(\xi, \eta)$. Denote respectively by $C_\xi(\xi, \eta)$ and $C_\eta(\xi, \eta)$ the connected components of ξ and η in $\bar{\mathcal{S}}(\xi, \eta)$. We assume

$$C_{w_i}(w_i, w_{i+1}) = \{w_i\} \quad \text{and} \quad C_{w_{i+1}}(w_i, w_{i+1}) = \{w_{i+1}\}, \\ \text{for } i = 1, \ldots, j-1. \tag{N}$$

It is shown in [70] that when these conditions fail then

$$C_{w_i}(w_i, w_{i+1}) = C_{w_{i+1}}(w_i, w_{i+1}),$$

which can be interpreted as a strongly degenerate situation.

THEOREM 2.6. *Assume* $V \in C^2(\mathbb{R} \times \mathbb{R}^N, \mathbb{R})$ *satisfies* (A7) *and* (A8). *Let there exist a basic heteroclinic chain of* (2.19), *consisting in the basic heteroclinics* v^i *with vertices* $\xi = w_1, \ldots, w_j = \eta$, *as described in Theorem* 2.5. *Then if* (N) *holds, the system* (2.19) *has infinitely many heteroclinic solutions connecting* ξ *and* η. *The time a solution spends in a neighbourhood of the vertices may be prescribed to exceed any arbitrary positive number.*

PROOF OF THEOREM 2.6. If I is an interval in $\mathbb{R}$, we write

$$\mathcal{J}_I(u) := \int_I \left(\frac{|u'|^2}{2} + V(t, u) \right) \mathrm{d}t.$$

By the nondegeneracy condition (N), given $\rho > 0$ we can fix open neighbourhoods A_i of w_i, B_{i+1} of w_{i+1} with diameter smaller than ρ and so that

$$\partial(A_i \cup B_{i+1}) \cap \bar{S}(w_i, w_{i+1}) = \emptyset, \quad \text{for } 1 \leqslant i \leqslant j-1. \tag{2.23}$$

We now consider a vector $z \in \mathbb{Z}^{2j-2}$ with coordinates

$$z_1 < z_2' < z_2 < z_3' < \cdots < z_j'$$

and define

$$X_z = \bigl\{ q \in \Gamma(\xi, \eta) \bigm| q(z_i) \in \bar{A}_i, q\bigl(z_{i+1}'\bigr) \in \bar{B}_{i+1}, i = 1, \ldots, j-1 \bigr\}.$$

The solutions we look for will be solutions of the following minimization problem:

$$b_z = \inf_{u \in X_z} \mathcal{J}(u) \tag{2.24}$$

provided that ρ is sufficiently small and the differences between the successive coordinates of z are sufficiently large. By the way, observe that the coordinates of z may be translated by any integer without affecting the variational problem.

CLAIM 1. *If* $0 < r < \frac{1}{3}$ *and* $\rho > 0$ *is sufficiently small*, b_z *is attained at a function* $u_z \in X_z$ *such that* $|u_z(t) - w_i| \leqslant r$ *for all* $t \in I_i$, *where* $I_i = [z_i', z_i]$, $i = 2, \dots, j-1$, $I_1 =]-\infty, z_1]$ *and* $I_j = [z_j', \infty[$.

Taking a minimizing sequence $(u_n)_n \subset X_z$ for (2.24), the claim follows from arguments similar to those we used in the proof of Theorem 2.3 that enable us to extract a convergent subsequence, still denoted by $(u_n)_n$, such that

$$u_n \overset{C_{\mathrm{loc}}(\mathbb{R},\mathbb{R}^N)}{\longrightarrow} u_z \quad \text{and} \quad u_n' \overset{L^2(\mathbb{R},\mathbb{R}^N)}{\rightharpoonup} u_z',$$

together with the fact that we may assume that the minimizing sequence satisfies the inequalities in the above statement. To see this last fact with respect to I_1, let $K(s, t; x, y)$ denote the affine map

$$\tau \to x + \frac{\tau - s}{t - s}(y - x), \quad s \leqslant \tau \leqslant t,$$

and consider the modified sequence $(U_n)_n \subset X_z$ defined by

$$U_n(t) = \begin{cases} w_1(t) & \text{if } t \leqslant z_1 - 1, \\ K\big(z_1 - 1, z_1; w_1, u_n(z_1)\big)(t) & \text{if } z_1 - 1 < t < z_1, \\ u_n(t) & \text{if } t \geqslant z_1. \end{cases}$$

A straightforward computation yields $\mathcal{J}_{I_1}(U_n) = o(\rho)$ as $\rho \to 0$. However if u_n reaches the boundary of $B_r(w_1)$ at some instant $t \in I_1$, the adaptation of Fact 1 of Section 2.2 to the present situation allows to prove $\mathcal{J}_{I_1}(u_n)$ is bounded from below by a constant depending only on r. Hence, if ρ is chosen sufficiently small, we may substitute U_n for u_n and the inequality follows. The same argument enables us to deal with the remaining intervals. This proves Claim 1.

CLAIM 2. *Let* $0 < \sigma < \rho$. *If the differences* $z_i - z_i'$ *are large enough, there exist subintervals* $J_i = [a_i, a_i + 2] \subset I_i$, *such that* $|u_z(t) - w_i| \leqslant \sigma$ *for all* $t \in J_i$ *and* $2 \leqslant i \leqslant j - 1$. *In addition* $\mathcal{J}_{J_i}(u_z) = o(\sigma)$ *as* $\sigma \to 0$.

By Claim 1, taking $z_i - z_i'$ large, we cannot have $|u_z(t) - w_i| \geqslant \sigma/2$ for all $t \in I_i$, since otherwise

$$\alpha_{\sigma/2}\big(z_i - z_i'\big) \leqslant \mathcal{J}_{I_i}(u_z) = o(\rho) \quad \text{for } \rho \to 0,$$

where $\alpha_{\sigma/2}$ is defined according to (2.20). In fact, the same argument shows that a subinterval $L \subset I_i$ with length greater than a certain $l > 0$ must contain at least one instant t such that $|u_z(t) - w_i| < \sigma/2$.

Suppose the first statement of Claim 2 is false. Then, each subinterval $J_i = [a_i, a_i + 2] \subset I_i$ containing an instant t where $|u_z(t) - w_i| < \sigma/2$ also contains an instant t' where $|u_z(t') - w_i| \geqslant \sigma$. If k is the number of such disjoint intervals, applying again the arguments of Fact 1 of Section 2.2 and the computations in the proof of Claim 1, we deduce a bound on k. Namely, we have

$$k\frac{\sigma}{2}\sqrt{2\alpha_{\sigma/2}} < o(\rho), \quad \text{for } \rho \to 0.$$

But, by the above remark, if $z_i - z_i'$ grows to infinity, so does k. This shows that the first statement of Claim 2 is true.

The second statement of Claim 2 is checked by noting that

$$\mathcal{J}_{J_i}(u_z) \leqslant \mathcal{J}_{J_i}(\psi) = o(\sigma), \quad \text{as } \sigma \to 0,$$

where ψ is defined by

$$\psi(t) := \begin{cases} u_z(t) & \text{if } t \in]-\infty, a_i[\cup]a_i+2, \infty[, \\ K\big(a_i, a_i+2, u_z(a_i), u_z(a_i+2)\big)(t) & \text{if } t \in [a_i, a_i+2]. \end{cases}$$

Let us now complete the proof. It is clear that $u_z(t)$ is a solution of (2.19) for $t \neq z_i,\ z_i'$. To prove that it is indeed a solution, we have to show that $u(z_i) \in A_i$ and $u(z_{i+1}') \in B_{i+1}$, for $1 \leqslant i \leqslant j-1$. To this purpose, an auxiliary variational problem is introduced: define

$$\Lambda(w_i, w_{i+1}) := \big\{u \in \Gamma(w_i, w_{i+1}) \mid u(0) \in \partial(A_i \cup B_{i+1})\big\}$$

and

$$d(w_i, w_{i+1}) := \inf_{u \in \Lambda(w_i, w_{i+1})} \mathcal{J}(u).$$

It is easily seen that this infimum is attained at some $S \in \Lambda(w_i, w_{i+1})$ and

$$d(w_i, w_{i+1}) > c(w_i, w_{i+1}).$$

Indeed, if there holds an equality, then $S(0) \in \partial(A_i \cup B_{i+1}) \cap \bar{S}(w_i, w_{i+1})$, contradicting (2.23).

Arguing by contradiction, assume that for some $i \in \{1, \dots, j-1\}$, we have, say,

$$u_z\big(z_{i+1}'\big) \in \partial B_{i+1}. \tag{2.25}$$

The other case may be handled in a similar way. By integer translation, we may suppose $z_{i+1}' = 0$. Also, we can translate the time variable in the basic heteroclinic v^i thus obtaining a new basic heteroclinic V^i such that $V^i(t) \in \bar{A}_i$ for $t \leqslant z_i$ and $V^i(t)$ leaves $\bar{A}_i$ at some time in $[z_i, z_{i+1}]$. Taking large differences $z_i - z_i'$ we may assume $V^i(t) \in \bar{B}_{i+1}$ for $t \geqslant z_{i+1}'$ as well. Hence $V^i(t) \in \bar{A}_i$ for $t \in J_i$ and $V^i(t) \in \bar{B}_{i+1}$ for $t \in J_{i+1}$.

Let us call U_z the modification of u_z outside $]-\infty, a_i] \cup [a_{i+1}+2, \infty[$ obtained by gluing together the following pieces: $K(a_i, a_i+1; u_z(a_i), w_i)$; $K(a_i+1, a_i+2; w_i, V^i(a_i+2))$;

the restriction of V^i to the interval $[a_i+2, a_{i+1}]$; $K(a_{i+1}, a_{i+1}+1; V^i(a_{i+1}), w_{i+1})$ and $K(a_{i+1}+1, a_{i+1}+2; w_{i+1}, u_z(a_{i+1}+2))$.

Finally we compute the difference

$$\mathcal{J}(u_z)-\mathcal{J}(U_z)=\mathcal{J}_{[a_i,a_{i+1}+2]}(u_z)-\mathcal{J}_{[a_i,a_{i+1}+2]}(U_z)$$

in the following way. Define an auxiliary curve γ_z by gluing together the constant w_i on $]-\infty, a_i]$; $K(a_i, a_i+1; w_i, u_z(a_i+1))$; u_z restricted to $[a_i+1, a_{i+1}]$; $K(a_{i+1}, a_{i+1}+1; u_z(a_{i+1}), w_{i+1})$ and the constant w_{i+1} in $[a_{i+1}+1, \infty[$. Note that $\gamma_z \in \Lambda(w_i, w_{i+1})$ by our assumption (2.25). Then we write

$$\begin{aligned}\mathcal{J}_{[a_i,a_{i+1}+2]}(u_z)-\mathcal{J}_{[a_i,a_{i+1}+2]}(U_z) &= \big(\mathcal{J}_{[a_i,a_{i+1}+2]}(u_z)-\mathcal{J}_{[a_i,a_{i+1}+2]}(\gamma_z)\big)\\ &\quad+\big(\mathcal{J}_{[a_i,a_{i+1}+2]}(\gamma_z)-\mathcal{J}_{[a_i,a_{i+1}+2]}(U_z)\big).\end{aligned}$$

Using Claim 2, we may check that the first difference on the right-hand side is an $o(\sigma)$ as $\sigma \to 0$. On the other hand, we clearly have

$$\mathcal{J}_{[a_i,a_{i+1}+2]}(\gamma_z) \geqslant b_z$$

and

$$\mathcal{J}_{[a_i,a_{i+1}+2]}(U_z) \leqslant \mathcal{J}_{[a_i,a_{i+1}+2]}\big(V^i\big)+o(\sigma), \quad \text{as } \sigma \to 0.$$

Hence, we finally deduce that

$$\begin{aligned}\mathcal{J}(u_z)-\mathcal{J}(U_z) &= \mathcal{J}_{[a_i,a_{i+1}+2]}(u_z)-\mathcal{J}_{[a_i,a_{i+1}+2]}(U_z)\\ &\geqslant b(w_i, w_{i+1})-c(w_i, w_{i+1})+o(\sigma), \quad \text{as } \sigma \to 0,\end{aligned}$$

leading to a contradiction with the minimizing property of u_z.

Conclusion. From what precedes, we conclude that for each $0<r<\frac{1}{3}$ and each vector $(z_1, z_2', z_2, z_3', \dots, z_j') \in \mathbb{Z}^{2j-2}$ such that the distances $z_i - z_i'$, $2 \leqslant i \leqslant j-1$, are large enough, there exists a heteroclinic solution u_z of (2.19) with the particularity that

$$\big|u_z(t)-w_i\big| \leqslant r, \quad \text{if } t \in \big[z_i', z_i\big], \quad \text{for } i=2,\dots,j-1$$

and

$$\big|u_z(t)-\xi\big| \leqslant r \quad \text{if } t \leqslant z_1, \qquad \big|u_z(t)-\eta\big| \leqslant r \quad \text{if } t \geqslant z_j'. \qquad \square$$

Several methods adapted to the search of multibump solutions may be found in the literature. For instance, in [67] Rabinowitz considers a system with two equilibria 0 and ξ and, starting from a pair of heteroclinics, v from 0 to ξ and w from ξ to 0, constructs heteroclinics that oscillate an arbitrary number of times between neighbourhoods of the equilibria. The method uses the functional $u \to \mathcal{J}(v+u)$ defined in $H^1(\mathbb{R}, \mathbb{R}^N)$. The concentration of Palais–Smale sequences with respect to homoclinics and heteroclinics is a crucial tool.

In [72], Coti Zelati and Rabinowitz give a variant of the result of Strobel for potentials of the form $V(t,u) = a(t)W(u)$ where W is periodic, a is slowly oscillating and not necessarily periodic.

The almost periodic case has been considered by Alessio, Bertotti and Montechiari [3] for fairly general Lagrangian systems. In particular, they show that, in presence of a slowly oscillating extra term, chaotic multibump dynamics arises.

2.4. *Notes and further comments*

1. In Theorem 2.1, the minimizer u takes values in $[-1,1]$. If (2.4) has uniqueness or if $F(u)$ lies below some quadratic function $c(u \pm 1)^2$ in the neighborhood of ∓ 1, we have $u(t) \in \,]-1,1[$ for all $t \in \mathbb{R}$. The heteroclinic of (2.4) is essentially unique (up to translation) as a consequence of (2.5) with $k = 0$.

2. If (2.9) has uniqueness of solutions for the Cauchy problem, the heteroclinics assume values in $]-1,1[$. In addition, if f has only one zero in $]-1,1[$, it can be checked that the minimizers of the functional $\mathcal{J}$ defined by (2.10) are strictly increasing. On the other hand, the presence of the function $a(t)$ in the functional rules out an easier argument which in the autonomous case shows that the elements of a minimizing sequence may assumed to be increasing functions.

3. In comparison with Theorem 2.2, the next theorem illustrates what can be said about second order systems where the potential depends on time and has no particular symmetry properties. For definiteness, consider the system

$$u'' = \nabla_u V(t,u), \tag{2.26}$$

where $u : \mathbb{R} \to \mathbb{R}^N$, $V \in C^2(\mathbb{R} \times \mathbb{R}^N, \mathbb{R})$ and ∇_u is the gradient with respect to the variable $u \in \mathbb{R}^N$. Assume that

(A9) $V(t,u) \geqslant 0$ for all $t \in \mathbb{R}$ and all $u \in \mathbb{R}^N$, and there exist $\xi \neq \eta$ such that $V(t,u) = 0$ if and only if $u \in \{\xi, \eta\}$;

(A10) there exist constants $a_1, a_2 > 0$ and $\varepsilon > 0$ such that $a_1|u-z|^2 \leqslant V(t,u) \leqslant a_2|u-z|^2$ if $z \in \{\xi, \eta\}$ and $|u-z| < \varepsilon$;

(A11) $\liminf_{|u| \to \infty} V(t,u) > 0$ uniformly in $t \in \mathbb{R}$.

Then one can prove:

THEOREM 2.7. *If* $V \in C^2(\mathbb{R} \times \mathbb{R}^N, \mathbb{R})$ *satisfies the assumptions* (A9)–(A11) *and*

$$t \frac{\partial V}{\partial t}(t,u) > 0$$

whenever $t \neq 0$ *and* $u \notin \{\xi, \eta\}$, *then* (2.26) *has a heteroclinic solution from* ξ *to* η.

This theorem is a particular case of the results proved by Chen and Tzeng [26]. In their paper, further examples of existence, and results on multiplicity of heteroclinics, may be found. Thus in this respect the non-autonomous equation behaves quite differently from the autonomous one. We also mention that the system considered there may have an infinite set of equilibria.

4. It is, however, interesting to note that, in contrast to Theorems 2.2 and 2.7, Korman and Lazer [46] consider a special scalar equation

$$u'' = a(t)\big(|u|^{p-1}u - u\big), \quad p > 1, \tag{2.27}$$

and they find a heteroclinic from -1 to 1 assuming that $a(t)$ is even, $a'(t) < 0$ if $t < 0$ and $a(\infty) > 0$. They exploit the symmetry of (2.27), solve the approximate two point problem with boundary conditions $u(0) = 0$, $u(T) = 1$ and then they pass to the limit as $T \to +\infty$.

5. Many other properties of heteroclinics of Hamiltonian systems have been established by means of variational methods. Let us list a few of them:

(i) *Heteroclinics to periodics.* Consider a system of the form

$$u'' = \nabla_u V(t, u) + f(t), \tag{2.28}$$

where V is a function of class C^2, 1-periodic in t and in the spacial variables, and f is continuous, 1-periodic and of zero mean value. Assume in addition that the system is *reversible*, namely that V and f are *even* in t. Then it is known that (2.28) has periodic solutions at the minimum level of the action functional corresponding to the periodic boundary value problem for (2.28). In [68] Rabinowitz gives conditions for the existence of heteroclinics *connecting two such periodic solutions*. In [53] Maxwell proves that there are heteroclinic chains between any two periodic solutions, the "vertices" of the chain being also periodic solutions.

Calanchi and Serra [24] use a constrained minimization approach for the existence of connections between consecutive periodic solutions. For ordinary differential equation, Bosetto and Serra [21] obtain multi-bump heteroclinics between consecutive periodic motions without any reversibility assumption.

(ii) *Heteroclinics to almost periodic solutions.* Alessio, Carminati and Montecchiari [4] prove the existence of heteroclinic connections joining almost periodic solutions of a Lagrangian system.

(iii) *Heteroclinics with an endpoint at infinity.* For potentials $V \in C^1(\mathbb{R}^N, \mathbb{R})$ with one zero at the origin and vanishing at infinity like some power $|u|^{-\alpha}$, $\alpha > 0$, the system (2.12) has at least one "heteroclinic at infinity", i.e. a solution $u(t)$ such that $u(-\infty) = 0$, $|u(+\infty)| = +\infty$ and $u'(\pm\infty) = 0$. We refer to Serra [80]. A similar result holds for a potential with a finite singularity when $N \geqslant 3$.

(iv) *Almost periodic systems.* Bertotti and Montecchiari [14] and Alessio, Bertotti and Montecchiari [3] consider almost periodic Lagrangian systems. Under suitable conditions, they obtain infinitely many heteroclinic solutions connecting possibly degenerate equilibria.

(v) *Singular potentials*. Many authors consider homoclinic solutions to equilibrium points of Hamiltonian systems with a singular potential, see [85,69,13,25] and the references therein. In case of a potential in $\mathbb{R}^2$ singular at some unique point, the basic result is the existence of many homoclinics classified according to their winding number around the singularity. It seems that only few attention was paid to heteroclinic connections with such settings. In [25] an autonomous system in $\mathbb{R}^2$ is considered. The origin is a minimum of the potential and a strong force at the singularity ξ is assumed. The authors obtain a certain periodic solution $\bar{u}$ with index 1 with respect to ξ, homoclinics with arbitrarily large indexes with respect to ξ and a heteroclinic from 0 to $\bar{u}$ which is built upon an infinite sequence of homoclinics. We already mentioned the result of Serra [80] about heteroclinics at infinity which holds in some singular frameworks. But up to our knowledge, no multiplicity results were obtained for heteroclinic solutions in the spirit of those concerning homoclinics.

(vi) *Heteroclinic connections between minima at different levels of the potential*. V. Coti Zelati and Rabinowitz [29] give conditions for the existence of a heteroclinic from χ to η for a system of the form

$$u'' = a(t)\nabla V(u),$$

where a is periodic and bounded away from zero and χ, η are isolated minima of V at *different* levels.

(vii) *Spatial heteroclinics*. Consider the PDE

$$\Delta u = a(x, y) f(u) \quad \text{in } \mathbb{R}^2, \tag{2.29}$$

where a is periodic in both variables and f is a non-negative smooth function such that $f(0) = f(1) = 0$. There are solutions $u(x, y)$ of (2.29) periodic in y and "heteroclinic in x" from 0 to 1, i.e. approaching respectively 0 and 1 as $x \to -\infty$ and $x \to +\infty$. This and a lot more of related results can be consulted in Rabinowitz and Stredulinsky [73, 74] and Rabinowitz [71]. See also the papers by Alessio, Jeanjean and Montecchiari [5, 6].

3. Heteroclinics as front wave profiles in reaction diffusion equations

An efficient model for many chemical and biological phenomena is provided by the partial differential equation

$$\frac{\partial u}{\partial t} + \frac{\partial}{\partial x} H(u) = \frac{\partial}{\partial x}\left[p(u)\frac{\partial u}{\partial x}\right] + g(u), \tag{3.1}$$

where $H, p \in C^1(\mathbb{R})$, $p > 0$ and following the terminology used in [49], g is a *function of type* A in [0, 1] by which we mean that

$$\begin{aligned}&g \text{ is continuous in } [0,1], \quad g(0) = g(1) = 0 \quad \text{and}\\ &g(u) > 0 \text{ if } u \in]0,1[.\end{aligned} \tag{Type A}$$

Hence the constants $u = 0$ and $u = 1$ are solutions of (3.1).

The first term in the right-hand side represents density dependent diffusion, while the term $\frac{\partial}{\partial x} H(u)$ accounts for convection effects.

An important problem related to this equation is that of finding positive travelling wave solutions, that is, positive solutions of the form $u(t,x) = U(x - ct)$ for some $c > 0$. Here c is the propagation speed of the wave. It is in addition required that the wave front $U(s)$ is defined in $]-\infty, +\infty[$ and satisfies $U(-\infty) = 1$, $U(+\infty) = 0$. This amounts to look at the solutions of the second order ordinary differential equation

$$\big(p(u)u'\big)' + \big(c - H'(u)\big)u' + g(u) = 0 \tag{3.2}$$

satisfying the limit conditions

$$u(-\infty) = 1, \quad u(+\infty) = 0.$$

We are therefore close to the problem of finding a heteroclinic between the equilibria 1 and 0.

The simplest and most classical case corresponds to $H \equiv 0$, $p \equiv 1$, the associated equation being then

$$u'' + cu' + g(u) = 0. \tag{3.3}$$

This (or the corresponding evolution equation) is usually referred as Fisher's equation, although in Fisher's original model $g(u)$ is the function $u(1-u)$. Among the vast literature on the existence of heteroclinics for (3.3) at least two contributions should be singled out: the pioneering work of Kolmogorov, Petrovsky and Piskounoff [45] and the paper by Aronson and Weinberger [11]—the latter concerning also diffusion in n-dimensional space. It is shown in [11] that, for $g \in C^1[0,1]$, there exists a heteroclinic connection of (3.3) between 1 and 0 if and only if $c \geqslant c^*$, where c^* is a positive number such that

$$2\sqrt{g'(0)} \leqslant c^* \leqslant 2\sqrt{\sup_{0<u<1} \frac{g(u)}{u}}.$$

The lower bound is clear, since linearizing (3.3) around $u = 0$ shows that for $c < 2\sqrt{g'(0)}$ the origin cannot act as an attractor of *positive* solutions. This result has been recently extended by Malaguti and Marcelli [48,49] for the more general problem (3.2) (in fact for even more general equations).

In this monograph we shall concentrate on the existence of heteroclinics and some bounds for the minimal speed c^*. Many other interesting problems concerning the equation (3.3) or systems of equations of this type have been dealt with in the literature. Some examples will be mentioned at the end of the section.

3.1. *Reduction to a first order equation*

Maybe the simplest way to obtain existence results for heteroclinic solutions of (3.2) or (3.3) consists in studying an equivalent first-order problem. This device may be found in [76] and has been extensively used in [49,50]. We modify it slightly, in the spirit of the approach given in [10].

Let us consider the equation (3.2) written as

$$\bigl(p(u)u'\bigr)' + h(u)u' + g(u) = 0 \tag{3.4}$$

and assume

(B1) $p \in C^1([0,1])$ and $p(u) > 0$ for all $u \in [0,1]$;
(B2) $h \in C[0,1]$ and $h(u) > 0$, for all $u \in [0,1]$;
(B3) g is a function of type A in $[0,1]$.

We first notice that monotone solutions of (3.4) such that $0 < u(s) < 1$ have no critical points. Indeed, if $u'(t_0) = 0$ and $0 < u(t_0) < 1$, then (3.4) implies $u''(t_0) < 0$. On the other hand, we observe that any decreasing solution $u(s)$ of (3.4) such that u is defined in $]-\infty, +\infty[$, $u(-\infty) = 1$ and $u(+\infty) = 0$ has the property

$$\lim_{s \to \pm\infty} u'(s) = 0, \tag{3.5}$$

so that u is indeed a heteroclinic between the equilibria 1 and 0. To prove (3.5) first remark that $\limsup_{s \to \pm\infty} u'(s) = 0$ by the boundedness of $u(s)$. Suppose, by contradiction, that $\liminf_{s \to +\infty} u'(t) < 0$, the limit at $-\infty$ is handled in a similar way. Let $t_n \to +\infty$ be a sequence so that $u'(t_n) \to 0$. Integrating (3.4) in $[0, t_n]$ shows that $\int_0^{t_n} g(u(s))\,\mathrm{d}s$ is bounded, whence by the positivity of g, we deduce that $\int_0^{+\infty} g(u(s))\,\mathrm{d}s$ is finite. Now let $t_n \to +\infty$ and $s_n \to +\infty$ be sequences so that $t_n < s_n < t_{n+1}$, $u'(t_n) \to 0$ and $u'(s_n) \to -\delta < 0$. From (3.4) we derive, for some $\tau_n \in [t_n, s_n]$

$$\begin{aligned}&\bigl[p\bigl(u(s_n)\bigr)u'(s_n) - p\bigl(u(t_n)\bigr)u'(t_n)\bigr] + h\bigl(u(\tau_n)\bigr)\bigl(u(s_n) - u(t_n)\bigr)\\&\quad + \int_{t_n}^{s_n} g\bigl(u(s)\bigr)\,\mathrm{d}s = 0.\end{aligned}$$

In the above equation the term in brackets has limit $-p(0)\delta$, while the remaining terms tend to 0, leading to a contradiction.

Now let $u = U(t)$ be a monotone decreasing heteroclinic of (3.4) and let $]t_-, t_+[$ be the maximal interval where

$$0 < U(t) < 1.$$

Then we have $U'(t) < 0$ for $t \in]t_-, t_+[$ and thus we can define $t(u)$, the inverse function of $u = U(t)$. Set

$$\varphi(u) := p\big[U\big(t(u)\big)\big]U'\big(t(u)\big). \tag{3.6}$$

Then φ is a C^1 function in $]0, 1[$ which can be continuously extended to $[0, 1]$ with $\varphi(0) = \varphi(1) = 0$. Moreover, φ satisfies

$$\varphi'(u)\varphi(u) + h(u)\varphi(u) + p(u)g(u) = 0.$$

Observe that the boundedness of h and the positivity of p and g implies that

$$\big|\varphi(u)\big| \leqslant ku$$

for some positive constant k. From Gronwall's inequality we then infer this rules out the possibility that $t_+ < +\infty$. Since $\varphi < 0$, we find that $\psi(u) := \varphi(u)^2$ is a solution of the first order differential equation

$$\psi'(u) = 2h(u)\sqrt{\psi(u)} - 2p(u)g(u) \tag{3.7}$$

in $[0, 1]$, together with the endpoint conditions

$$\psi(0) = \psi(1) = 0. \tag{3.8}$$

In particular, ψ is of type A in $[0, 1]$.

Conversely, if (3.7) has a solution ψ of type A in $[0, 1]$, we use it to define the solution $u(t)$ of the Cauchy problem

$$u' = -\frac{\sqrt{\psi(u)}}{p(u)}, \qquad u(0) = \frac{1}{2}. \tag{3.9}$$

The domain of this solution is $]t_-, t_+[$, where

$$t_- = -\int_{1/2}^{1} \frac{p(u)\,\mathrm{d}u}{\sqrt{\psi(u)}}, \qquad t_+ = \int_0^{1/2} \frac{p(u)\,\mathrm{d}u}{\sqrt{\psi(u)}}.$$

The boundedness of h and (3.7) imply that in a neighborhood of $u = 0$, we have

$$\sqrt{\psi(u)} \leqslant ku$$

for some positive constant k. Therefore it follows from assumption (B1) that $t_+ = +\infty$. If we assume in addition that

(B4) there exists $\ell > 0$ such that for all $u \in [0, 1]$, $g(u) \leqslant \ell(1 - u)$, then we infer from (3.7) that there exists some constant $k_1 > 0$ so that $\psi(u) \leqslant k_1(1-u)^2$ in a neighborhood of $u = 1$. Hence under the condition (B4) we also have $t_- = -\infty$.

A straightforward computation shows that $u(t)$ satisfies (3.4) in $]t_-, t_+[$, and it is clear that

$$\lim_{t\to t_-} u(t) = 1, \qquad \lim_{t\to t_+} u(t) = 0, \qquad \lim_{t\to t_\pm} u'(t) = 0.$$

Therefore we have shown:

PROPOSITION 3.1. *Assume* (B1)–(B4) *hold and let* φ *be the function defined by* (3.6). *Then* $u = U(t)$ *is a* (*strictly*) *decreasing heteroclinic solution of* (3.4) *between* 1 *and* 0 *if and only if* $\varphi(u)^2$ *is a solution of type A of* (3.7) *in* [0, 1].

REMARK. Under weaker hypotheses, namely if we allow a singularity at zero, i.e. $p(0) = 0$, or in the absence of (B4), t_- or t_+, or both, may be finite. In these cases, we still obtain a heteroclinic by trivially extending $U(t)$ with the value 1 to the left and with the value 0 to the right.

Proposition 3.1 reduces the existence of heteroclinics for (3.4) to the existence of type A solutions of (3.7). Therefore it is useful to have criteria that ensure existence of such solutions.

PROPOSITION 3.2. *Assume* (B1)–(B3) *hold.*

(i) *Suppose that* $s(u)$ *is a* C^1 *function in* [0, 1] *such that* $s(0) = 0$, $s(u) > 0$ *if* $u \in]0, 1[$ *and for all* $u \in [0, 1]$,

$$s'(u) \leqslant 2h(u)\sqrt{s(u)} - 2p(u)g(u). \tag{3.10}$$

Then Eq. (3.7) *has a solution of type A.*

(ii) *Equation* (3.7) *has at most one solution of type A.*

PROOF. (i) The assumption (3.10) which means s is a lower solution of the initial value problem

$$\begin{aligned} &\psi' = 2h(u)\sqrt{\psi} - 2p(u)g(u), \\ &\psi(0) = 0, \end{aligned} \tag{3.11}$$

implies, as is well known (see, e.g., [91]), that (3.11) has a solution $\psi(u)$ such that $\psi(u) \geqslant s(u)$. If $\psi(1) = 0$ then ψ is a type A solution of (3.7) and we are done.

If $\psi(1) > 0$, we consider the solution $\bar{\psi}$ of the initial value problem

$$\begin{aligned} &\bar{\psi}' = 2h(u)\sqrt{|\bar{\psi}|} - 2p(u)g(u), \\ &\bar{\psi}(1) = 0. \end{aligned} \tag{3.12}$$

It is clear that we may assume $\bar{\psi} \geqslant 0$ in $[0, 1]$, since 0 is a lower solution for the initial value problem (3.12) in $[0, 1]$. We claim that $0 < \bar{\psi}(u) < \psi(u)$ for all $u \in]0, 1[$. In fact, if u_0 is the largest zero of $\bar{\psi}$ in $]0, 1[$, then (3.12) implies $\bar{\psi}'(u_0) < 0$, which is impossible. If $u_1 \in]0, 1[$ is such that $\bar{\psi}(u_1) = \psi(u_1)$, then $\bar{\psi} \equiv \psi$, which is also impossible. Hence the claim is proved and by continuity, $\bar{\psi}(0) = 0$ so that $\bar{\psi}$ is the desired solution of type A.

(ii) Assume by contradiction that ψ_1 and ψ_2 are distinct type A solutions of (3.7). By uniqueness of the solution of the Cauchy problem, these two solutions are ordered, say $\psi_1(u) < \psi_2(u)$ for all $u \in]0, 1[$. But then (3.7) shows that $\psi_2 - \psi_1$ is increasing and this contradicts $\psi_1(1) = \psi_2(1) = 0$. □

The results we have established have straightforward consequences:

PROPOSITION 3.3.
(i) *The decreasing heteroclinic of* (3.4), *if it exists, is unique up to translation.*
(ii) *Consider two equations*

$$\bigl(p_i(u)u'\bigr)' + h_i(u)u' + g_i(u) = 0, \quad i = 1, 2, \tag{$*$}_i$$

where p_i, h_i, g_i satisfy assumptions (B1)–(B4). *Then if $h_1 \leqslant h_2$, $p_1 \geqslant p_2$ and $g_1 \leqslant g_2$, and* $(*)_1$ *has a decreasing heteroclinic, then so does* $(*)_2$.

REMARK. If $c_1 < c_2$ the heteroclinics u_1, u_2 of (3.3) with respectively $c = c_1$, c_2 satisfy $\psi_2 < \psi_1$ by the above ordering argument.

EXAMPLES. (1) Suppose H' in (3.2) is continuous. Then there exists a number $c^* \in \mathbb{R}$ such that (3.2) admits a decreasing solution if and only if $c \geqslant c^*$. In particular, for (3.3) we have the classical estimate

$$0 < c^* \leqslant 2\sqrt{\sup_{0<u<1} \frac{g(u)}{u}}. \tag{3.13}$$

In fact, if there exists $M > 0$ so that for all $u \in [0, 1]$, $g(u) \leqslant Mu$, then we can choose a constant $\beta > 0$ so that $s(u) = \beta u^2$ is a lower solution of (3.11) with $h(u) \equiv c$, $p(u) \equiv 1$, provided that $c^2 \geqslant 4M$.

(2) Consider the autonomous case

$$u'' + cu' + g(u) = 0$$

in which there exists $M > 0$ and $\alpha \geqslant 2$ so that

$$g(u) \leqslant Mu^\alpha(1 - u).$$

(This type of nonlinear term appears in many applications.) It is easy to see that $s = \beta u^\alpha(1 - u)^2$ is a lower solution of (3.11) with $h(u) \equiv c$, $p(u) \equiv 1$, if for all $u \in [0, 1]$,

$$\alpha\beta u^{\alpha/2-1} + \bigl(2M - \beta(\alpha + 2)\bigr)u^{\alpha/2} \leqslant 2c\sqrt{\beta}.$$

Elementary but tedious computations show that such a number $\beta > 0$ exists if $c \geqslant \sqrt{2M}\big(\frac{\alpha-1}{\alpha+2}\big)^{(\alpha-1)/2}$. We thus obtain

$$c^* \leqslant \sqrt{2M}\left(\frac{\alpha-1}{\alpha+2}\right)^{(\alpha-1)/2},$$

an estimate which improves, for small values of α (e.g., $\alpha \leqslant 4$) that allowed by (3.13).

3.2. *Fast solutions and heteroclinics*

In this section we consider the simple model

$$u'' + cu' + g(u) = 0 \tag{3.14}$$

with g of type A. Following [10] we say that a solution $u(t)$ of (3.14) is a *fast solution* if it is defined in some interval $[t_0, +\infty]$ and satisfies the integrability condition

$$\int_{t_0}^{+\infty} \mathrm{e}^{ct} u'(t)^2 \,\mathrm{d}t < +\infty.$$

In order to look for this kind of solutions we introduce the Hilbert space

$$H_c = \left\{ u \in H^1_{\mathrm{loc}}(0, +\infty) \;\middle|\; \int_0^{+\infty} \mathrm{e}^{ct} u'(t)^2 \,\mathrm{d}t < +\infty \text{ and } u(+\infty) = 0 \right\}$$

with the norm

$$\|u\| = \left(\int_0^{+\infty} \mathrm{e}^{ct} u'(t)^2 \,\mathrm{d}t \right)^{1/2}.$$

Note that $u(+\infty)$ exists whenever the above integral is finite, since by Schwarz's inequality

$$\big|u(T) - u(S)\big| \leqslant \left(\frac{|\mathrm{e}^{-cS} - \mathrm{e}^{-cT}|}{c} \int_S^T \mathrm{e}^{ct} u'(t)^2 \,\mathrm{d}t \right)^{1/2}.$$

On the other hand, taking limits in the above inequality as $T \to +\infty$ it turns out that for all $u \in H_c$

$$\|u\|_{L^\infty(S,+\infty)} \leqslant \frac{\mathrm{e}^{-cS/2}}{\sqrt{c}} \|u\|. \tag{3.15}$$

PROPOSITION 3.4. *For all $u \in H_c$, we have*

$$\frac{c^2}{4} \int_0^{+\infty} \mathrm{e}^{ct} u(t)^2 \,\mathrm{d}t \leqslant \int_0^{+\infty} \mathrm{e}^{ct} u'(t)^2 \,\mathrm{d}t. \tag{3.16}$$

PROOF. In Hardy's inequality (see [40])

$$\int_0^{+\infty} \frac{v(s)^2}{s^2}\,\mathrm{d}s \leqslant 4\int_0^{+\infty} v'(s)^2\,\mathrm{d}s,$$

where v is absolutely continuous in $[0,+\infty[$ and $v(0)=0$, make the change of variables $v(s)=u(t)$, $s=\mathrm{e}^{-ct}$ to obtain

$$c\int_{-\infty}^{+\infty} \mathrm{e}^{ct}u(t)^2\,\mathrm{d}t \leqslant \frac{4}{c}\int_{-\infty}^{+\infty} \mathrm{e}^{ct}u'(t)^2\,\mathrm{d}t.$$

Then choose $u(t)$ to be constant for $t\leqslant 0$ and ignore, in the left-hand side of the estimate, the integral over $]-\infty,0]$ which is positive. □

Assume that g satisfies
(B5) $\sup_{0<u<1}\frac{g(u)}{u}<+\infty$
and extend $g(u)$ to $]-\infty,\infty[$ with the value 0 outside $[0,1]$. Solutions of (3.14) defined in $[0,+\infty[$ and taking values in $[0,1]$ can thus be identified with critical points of the functional $\mathcal{F}\colon H_c\to\mathbb{R}$ defined by

$$\mathcal{F}(u)=\int_0^{+\infty}\mathrm{e}^{ct}\left(\frac{u'^2}{2}-G(u)\right)\mathrm{d}t,$$

where $G(s)=\int_0^s g(\tau)\,\mathrm{d}\tau$. In fact, one can check that under the assumption (B5), $\mathcal{F}$ is a functional of class C^1 in H_c and (3.14) (with the extended g) is the Euler–Lagrange equation for $\mathcal{F}$.

Let us introduce one more assumption:
(B6) there exists a constant k such that $k\in\,]0,c^2/4[$ and

$$G(u)\leqslant\frac{ku^2}{2},\qquad \text{for } 0\leqslant u\leqslant 1.$$

PROPOSITION 3.5. *Assume* (B3), (B5) *and* (B6) *hold. Then* $\mathcal{F}$ *attains a minimum in the set*

$$M=\bigl\{u\in H_c \mid u(0)=1\bigr\}.$$

The minimizer u *is a solution of* (3.14) *in* $[0,+\infty[$ *such that for all* $t\geqslant 0$, $u'(t)\leqslant 0$ *and* $0\leqslant u(t)\leqslant 1$.

PROOF. We write $\mathcal{F}$ in the form

$$\mathcal{F}(u)=\int_0^{+\infty}\mathrm{e}^{ct}\left(\frac{u'^2}{2}-k\frac{u^2}{2}\right)\mathrm{d}t+\int_0^{+\infty}\mathrm{e}^{ct}H(u)\,\mathrm{d}t, \tag{3.17}$$

where by (B6),

$$H(u) = k\frac{u^2}{2} - G(u) \geqslant 0.$$

Let $(u_n)_n \subset M$ be a minimizing sequence for $\mathcal{F}$. Since $G(u) = G(\max(0, \min(1, u)))$, it is clear that arguing as in the proof of Theorem 2.1, we may assume $0 \leqslant u_n \leqslant 1$. Because of (3.16), the first integral in (3.17) is the square of an equivalent norm in H_c. Hence $(u_n)_n$ is bounded and, passing to a subsequence we may assume that there exists $u \in H_c$ so that $u_n \rightharpoonup u$ in H_c and $u_n \to u$ uniformly in compact intervals. In particular $u \in M$ and, by the lower semicontinuity of the norm and Fatou's lemma, we infer from (3.17) that

$$\mathcal{F}(u) \leqslant \liminf_{n\to\infty} \mathcal{F}(u_n).$$

Hence u is a minimizer of $\mathcal{F}$ in M. Since $0 \leqslant u \leqslant 1$, $u(t)$ is a solution of (3.14) with $u(0) = 1$. Writing (3.14) as

$$\left(\mathrm{e}^{ct}u'\right)' + \mathrm{e}^{ct}g(u) = 0 \tag{3.18}$$

we see that $\mathrm{e}^{ct}u'$ is decreasing, hence for all $t \geqslant 0$ we have $u'(t) \leqslant 0$. □

THEOREM 3.6. *Assume* (B3), (B5) *and* (B6) *hold. Then* (3.14) *has a heteroclinic connecting* 1 *and* 0.

PROOF. Let U be the solution found in the preceding proposition. If $U'(0) = 0$, then extending U with value 1 on $]-\infty, 0]$ we obtain a heteroclinic solution. Otherwise, we have $U'(t) < 0$, $0 < U(t) \leqslant 1$ for all $t \geqslant 0$ and we may define $\varphi(u) = U'(t(u))$ for $0 \leqslant u \leqslant 1$ as in (3.6). We thus obtain a solution $\psi(u) = \varphi(u)^2$ of (3.7) (with $p \equiv 1$, $h \equiv c$), such that $\psi(0) = 0$ and $\psi(u) > 0$ if $0 < u \leqslant 1$. It now follows from Proposition 3.2 that (3.7) has a solution of type A and Proposition 3.1 allows to conclude. □

We then have the straightforward corollary:

COROLLARY 3.7. *For a given function g of type A satisfying* (B5), *the threshold speed of Eq.* (3.14) *satisfies*

$$c^* \leqslant 2 \sup_{0<u<1} \sqrt{\frac{2G(u)}{u^2}}.$$

To end this section we illustrate the use of variational and comparison arguments to obtain a heteroclinic for a nonautonomous equation (see also [50] for further results relative to the non-autonomous case). We consider

$$u'' + p(t)u' + g(u) = 0, \tag{3.19}$$

where p is a continuous function in $\mathbb{R}$ such that

(B7) there exist $0 < c < d < +\infty$ such that for any $t \in \mathbb{R}$, $c \leqslant p(t) \leqslant d$.

As above, we make use of a weighted space of functions:

$$X_\tau = \left\{ u \in H^1_{\mathrm{loc}}(\tau, +\infty) \;\middle|\; \int_\tau^{+\infty} \mathrm{e}^{P(t)} u'(t)^2 \,\mathrm{d}t < +\infty \text{ and } u(+\infty) = 0 \right\},$$

where τ is taken negative and $P(t) = \int_0^t p(s)\,\mathrm{d}s$. Arguing as in the proof of Proposition 3.4 and assuming p satisfy (B7), we derive the inequality

$$\frac{c^2}{4} \int_\tau^{+\infty} \mathrm{e}^{P(t)} u(t)^2 \,\mathrm{d}t \leqslant \int_\tau^{+\infty} \mathrm{e}^{P(t)} u'(t)^2 \,\mathrm{d}t, \tag{3.20}$$

which is valid for any $u \in X_\tau$. On the other hand, it is easily seen that for any $u \in X_\tau$ we have the estimate

$$\|u\|_{L^\infty(0,+\infty)} \leqslant C \left(\int_0^{+\infty} \mathrm{e}^{P(t)} u'(t)^2 \,\mathrm{d}t \right)^{1/2} \tag{3.21}$$

for some positive constant C.

THEOREM 3.8. *Assume* (B3) *holds*, $p \in C(\mathbb{R})$ *satisfies* (B7), g *is Lipschitz in* $[0, 1]$ *and there exists* $k < c^2/4$ *such that*

$$g(u) \leqslant ku, \quad \textit{for } u \in [0, 1]. \tag{3.22}$$

Then, *given* $a \in\,]0, 1[$, (3.19) *has a strictly decreasing heteroclinic connecting* 1 *and* 0 *and satisfying* $u(0) = a$.

PROOF. We outline the proof in four steps.

Step 1. We claim that the linear equation

$$\varphi'' + p(t)\varphi' + k\varphi = 0 \tag{3.23}$$

has a solution φ_τ such that $\varphi_\tau(\tau) = 1$, $0 < \varphi_\tau < 1$ in $]\tau, +\infty[$ and $\varphi_\tau \in X_\tau$.

Indeed, it suffices to take φ_τ as the minimizer of the quadratic functional

$$\mathcal{F}_\tau(u) = \int_\tau^{+\infty} \mathrm{e}^{P(t)} \left(\frac{u'^2}{2} - k\frac{u^2}{2} \right) \mathrm{d}t$$

in the convex set $\{u \in X_\tau \colon\ u(\tau) = 1\}$. It is easy to see, on the basis of (3.20) which remains valid with τ substituted by any $\xi \geqslant \tau$, that in fact $\varphi_\tau > 0$. Observe also that, multiplying the self-adjoint form of (3.23) by φ_τ and integrating by parts, we infer that $\mathrm{e}^{P(t)}\varphi'(t)\varphi(t)$ has limit as $t \to +\infty$. It then follows from (3.20) and the fact that $\varphi_\tau > 0$ that this limit is negative. This in turn implies that $\varphi_\tau'(\tau) < 0$ and $\varphi_\tau < 1$ in $]\tau, +\infty[$. Hence this step is completed.

Step 2. We claim $\lim_{\tau\to-\infty} \varphi_\tau(0) = 0$.

Given $\beta > 0$, we first evaluate $\mathcal{F}_\tau$ on the test function $u(t) = \mathrm{e}^{-(\beta/2)P(t-\tau)}$ and obtain

$$\mathcal{F}_\tau(\varphi_\tau) = \inf_{X_\tau} \mathcal{F}_\tau \leqslant \frac{\beta^2 d^2}{8} \int_0^{+\infty} \mathrm{e}^{P(\tau+t)-\beta P(t)}\,\mathrm{d}t. \tag{3.24}$$

From the inequality (3.20), we come out with the estimate

$$\mathcal{F}_\tau(\varphi_\tau) \geqslant \frac{1}{2}\left(1 - \frac{4k}{c^2}\right) \int_\tau^{+\infty} \mathrm{e}^{P(t)} \varphi_\tau'(t)^2\,\mathrm{d}t. \tag{3.25}$$

It then follows from the inequalities (3.24), (3.25) and $k < c^2/4$ that

$$\int_0^{+\infty} \mathrm{e}^{P(t)} \varphi_\tau'(t)^2\,\mathrm{d}t \leqslant C \int_0^{+\infty} \mathrm{e}^{P(\tau+t)-\beta P(t)}\,\mathrm{d}t$$

for some $C \geqslant 0$ and consequently we deduce from Step 1 and (3.21) that there exists a number $L \geqslant 0$ such that for all $\tau < 0$,

$$0 < \varphi_\tau(0) \leqslant L \left(\int_0^{+\infty} \mathrm{e}^{P(\tau+t)-\beta P(t)}\,\mathrm{d}t \right)^{1/2}.$$

If we take $\beta > d/c$, we may apply the dominated convergence theorem to the integral in the right-hand side and conclude that

$$\lim_{\tau\to-\infty} \varphi_\tau(0) = 0.$$

Step 3. Let $\tau < 0$ be such that $\varphi_\tau(0) < a$. From (3.22) it follows that φ_τ is an upper solution of (3.19) with respect to the two-point boundary conditions $u(\tau) = 1$, $u(0) = 0$. Since 0 is a lower solution, we obtain a solution v of (3.19) in $[\tau, 0]$ such that $v(\tau) = 1$, $v(0) = 0$, $0 \leqslant v \leqslant \varphi_\tau$. This in turn is a lower solution in $[\tau, 0]$ with respect to the boundary conditions $u(\tau) = 1$, $u(0) = a$. Since 1 is an upper solution, there is a solution u_τ of (3.19) such that

$$u_\tau(\tau) = 1, \qquad u_\tau(0) = a, \qquad v \leqslant u_\tau \leqslant 1 \quad \text{in } [\tau, 0].$$

We claim that the solution u_τ satisfies for all $t \geqslant 0$,

$$u_\tau(t) \geqslant \varphi_\tau(t) > 0.$$

Otherwise, since $u_\tau(\tau) = \varphi(\tau)$ and $u_\tau(0) > \varphi_\tau(0)$, there exist t_0, t_1 such that $\tau \leqslant t_0 < 0$, $t_0 < t_1 \leqslant +\infty$, $u_\tau(t_i) = \varphi_\tau(t_i)$ for $i = 0, 1$, $u_\tau > \varphi_\tau$ in $]t_0, t_1[$. Multiplying the self-adjoint forms of (3.19) and (3.23) respectively by φ_τ and u_τ, and integrating by parts, we obtain

$$\left[\mathrm{e}^{P(t)}\left(u_\tau'(t)\varphi_\tau(t) - u_\tau(t)\varphi_\tau'(t)\right)\right]_{t_0}^{t_1} + \int_{t_0}^{t_1} \mathrm{e}^{P(t)}\left(g(u_\tau)\varphi_\tau - k u_\tau\varphi_\tau\right) \mathrm{d}t = 0. \tag{3.26}$$

On the other hand, since g satisfies a Lipschitz condition in $[0, 1]$, we must have $u_\tau'(t_0) > \varphi_\tau'(t_0)$ and $u_\tau'(t_1) \leqslant \varphi_\tau'(t_1)$. But then using (3.22), we conclude that the left-hand side of (3.26) is strictly negative, yielding a contradiction.

Step 4. From the last two steps it follows that we may define a sequence $\tau_n \to -\infty$ and a corresponding sequence $u_n = u_{\tau_n}$ of solutions of (3.19) such that

$$u_n(\tau_n) = 1, \qquad u_n(0) = a \qquad \text{and} \qquad 0 < u_n < 1 \quad \text{in }]\tau_n, +\infty[.$$

A diagonal argument, based on simple estimates on the sequence $(u_n)_n$, shows that some subsequence converges to a solution u of (3.19) in $]-\infty, +\infty[$ such that $u(0) = a$ and $0 < u < 1$. It is easy to see that $u' < 0$, $u(-\infty) = 1$, $u(+\infty) = 0$ and indeed u is the desired heteroclinic solution. □

3.3. *Heteroclinics in a combustion model*

In this section we consider the differential equation

$$u'' + cu' + f(u) = 0, \tag{3.27}$$

where $f \in C([0, 1], \mathbb{R})$ has the following behaviour:

(B8) $f(0) = f(1) = 0$;
(B9) there exists $a \in]0, 1[$ such that $f(u) < 0$ if $u \in]0, a[$;
(B10) $\int_0^1 f(t)\,\mathrm{d}t > 0$.

Equation (3.27) with this type of nonlinearity arises as the front wave equation for some combustion models. We refer the reader to [12,33,52] for a study in depth of related problems. Here we confine ourselves to look for solutions of (3.27) which are monotone heteroclinics connecting the equilibria 1 and 0.

Note that by virtue of assumptions (B9) and (B10), Eq. (3.27) has at least one more equilibrium between 0 and 1. The behavior of solutions of (3.27) is quite different from those of (3.14). The main result describing the existence of heteroclinics in terms of the parameter c is the following.

THEOREM 3.9. *Assume* (B8)–(B10) *hold and suppose in addition that* $f(u) > 0$ *for* $\xi < u < 1$, *where* ξ *is the smallest number in* $]0, 1[$ *with the property that* $\int_0^\xi f(t)\,\mathrm{d}t = 0$. *Then there exists a unique* $c^* > 0$ *such that* (3.27) *has a heteroclinic solution* $u(t)$, *connecting* 1 *and* 0, *with the property that* $u'(t) < 0$ *for all* $t \in \mathbb{R}$. *Moreover, this heteroclinic is unique up to translation.*

PROOF. In order to prove this theorem we proceed as in Section 3.1, obtaining the desired heteroclinic by means of a solution to the first-order problem (3.9) where $\psi(u)$ is a positive solution of

$$\psi'(u) = 2c\sqrt{\psi(u)} - 2f(u) \tag{3.28}$$

in [0, 1], $\psi(0) = 0 = \psi(1)$ and $p \equiv 1$. Let us therefore study the Cauchy problem

$$\begin{aligned} &\psi' = 2c\sqrt{\psi_+} - 2f(u),\\ &\psi(0) = 0, \end{aligned} \tag{3.29}$$

where $\psi_+(u) = \max(\psi(u), 0)$.

Step 1. Given $c \geqslant 0$, (3.29) has a unique solution in [0, 1].

If $c = 0$ the solution is $\psi_0(u) = -2F(u) := -2\int_0^u f(t)\,\mathrm{d}t$. Now assume $c > 0$. It is clear that any solution ψ of (3.29) satisfies $\psi(u) > \psi_0(u)$ if $0 < u \leqslant 1$. In particular we have $\psi(u) > 0$ in $]0, a[$. Write $\psi = \theta - 2F(u)$, so that in a right neighborhood of zero θ is a solution of

$$\begin{aligned} &\theta' = 2c\sqrt{\theta - 2F(u)},\\ &\theta(0) = 0. \end{aligned} \tag{3.30}$$

If ψ_1, ψ_2 are distinct positive solutions of (3.29), then they are ordered in a neighborhood of 0 that is $\psi_1(u) < \psi_2(u)$ and so are the corresponding solutions of (3.30): $\theta_1(u) < \theta_2(u)$. Since these are strictly increasing near zero we obtain, for their inverse functions $u_i(\theta)$ $(i = 1, 2)$ in some interval $0 < \theta \leqslant b$,

$$\frac{\mathrm{d}u_i}{\mathrm{d}\theta} = \frac{1}{2c\sqrt{\theta - 2F(u_i)}}$$

and $u_i(0) = 0$. However, since $-2F$ is strictly increasing in a neighborhood of zero, we may assume that $-2F(u_2) < -2F(u_1)$ and therefore $u_2 - u_1$ is increasing in $[0, b]$. This contradicts $u_1(0) = 0 = u_2(0)$. Hence the solution ψ of (3.29) is unique at least as long as it is strictly positive. Assume that $\psi(\tau) = 0$ for some $0 < \tau < 1$. We clearly have $\tau > \xi$ and, in view of our assumptions, $\psi'(\tau) < 0$. But then (3.29) implies $\psi(u) = -2\int_\tau^u f(t)\,\mathrm{d}t$ for $\tau \leqslant u \leqslant 1$.

Step 2. There exists $c > 0$ such that the solution $\psi_c(u)$ of (3.29) satisfies $\psi_c(1) > 0$.

It suffices to note that, if we set

$$M = \sup_{0<u<1} \frac{f(u)}{u}$$

and choose $c > 1 + M$, then u^2 is a lower solution of (3.29).

Step 3. Uniqueness and the fact that solutions of (3.29) are uniformly bounded when c runs over bounded sets, imply that the solution $\psi_c(u)$ of (3.29) depends continuously on c. By assumption *(B10)*, we infer that $\psi_0(1) < 0$. By Step 2 we conclude that there exists $c^* > 0$ such that $\psi_{c^*}(1) = 0$. Moreover, by uniqueness and a standard comparison theorem, $\psi_c(1)$ is strictly increasing as a function of c, so that c^* is unique.

To complete the proof, if suffices to observe that a solution of (3.29) with $\psi(1) = 0$ satisfies $\psi(u) > 0$ if $0 < u < 1$ and is therefore a solution of (3.28). But this is a straightforward consequence of the argument used at the end of Step 1. ☐

3.4. *Notes and further comments*

1. Elementary approaches to the existence of the travelling front solutions, for an equation or a system with two equilibria, can be found in [2,77,78] (in [78] a class of nonautonomous systems is considered). Front waves and their minimal speed are studied in [32] for two-dimensional systems with four equilibria.

2. Comparison techniques are used in [44] to give analytic approximation of the front solutions.

3. We might have enlarged the scope of the results described here by considering the presence of singularities, namely $p(0) = 0$ in (3.1). Such singularities are important in applications. In [51] Malaguti and Marcelli study the problem

$$\big(p(u)u'\big)' + cu' + g(u) = 0, \tag{3.31}$$

where g is of type A and p is a C^1 function with $p(0) = 0$ and $p'(0) > 0$. In addition to decreasing heteroclinics between 1 and 0 there appear *sharp type* solutions, by which one understands decreasing solutions $u(t)$ of (3.31) in $]-\infty, 0]$ such that $u(-\infty) = 1$, $u(0) = 0$ and $u'(0) = -c/p'(0)$. It turns out that a threshold speed c^* exists such that (3.31) has a decreasing heteroclinic from 1 to 0 if $c > c^*$, a sharp type solution if $c = c^*$ and no solution of either type if $c < c^*$.

4. Hamel and Nadirashvili [39] use front wave solutions of

$$\frac{\partial u}{\partial t} = \frac{\partial^2 u}{\partial x^2} + g(u),$$

with g concave of type A, to construct an infinite dimensional manifold of entire solutions.

5. A wealth of results concerning wavefronts and their admissible speeds can be found in the recent monograph by Gilding and Kersner [35].

Part 2. Fourth Order Equations

4. The Extended Fisher–Kolmogorov equation: An overview

The class of fourth order differential equations considered in this survey is related to semilinear evolution equations of the form

$$\frac{\partial u}{\partial t} + \frac{\partial^4 u}{\partial x^4} - \beta \frac{\partial^2 u}{\partial x^2} + u^3 - u = 0, \tag{4.1}$$

where β is a real parameter. This equation serves as a model in studies of pattern formation in many physical, chemical or biological systems. It also arises in the study of phase transitions.

When $\beta > 0$, it is related to the so-called *Extended Fisher–Kolmogorov* equation which was proposed in 1988 by Dee and van Saarloos [30] as a higher-order model equation for *bistable* systems. The term bistable indicates that the states $u = \pm 1$ are stable for the homogenized equation $-u' = u^3 - u$. When suitably scaled, solutions of (4.1) solve the equation

$$\frac{\partial v}{\partial t} + \gamma \frac{\partial^4 v}{\partial x^4} - \frac{\partial^2 v}{\partial x^2} + v^3 - v = 0, \tag{4.2}$$

where the positive parameter γ is related to β by the formula $\beta = 1/\sqrt{\gamma}$ and $v(x,t) = u(\sqrt{\beta} x, t)$. When $\gamma = 0$ in (4.2), the equation is a second order evolution equation (of Fisher type) which enters into the framework of Section 3. It is often referred to as the Fisher–Kolmogorov equation.

In this section, we summarize recent results concerning the existence of heteroclinic solutions for the stationary Extended Fisher–Kolmogorov equation

$$u'''' - \beta u'' + u^3 - u = 0. \tag{4.3}$$

Heteroclinic solutions of (4.3) connecting -1 to $+1$ in the phase-space satisfy the following conditions

$$\lim_{x \to \pm\infty} \big(u, u', u'', u'''\big)(x) = (\pm 1, 0, 0, 0). \tag{4.4}$$

Of course, we can also consider connections from $+1$ to -1 by reversing the role of $\pm\infty$ in the above condition.

The parameter β plays a central role in the analysis of the behaviour of solutions of (4.3). Indeed, the nature of the equilibria ± 1 changes at two critical values $\beta = \pm\sqrt{8}$. The linearization of (4.3) at $u = \pm 1$ reads

$$v'''' - \beta v'' + 2v = 0, \tag{4.5}$$

where v stands respectively for $u-1$ and $u+1$. The eigenvalues of the associated characteristic equation

$$\lambda^4-\beta\lambda^2+2=0$$

are

$$\lambda=\pm\sqrt{\frac{\beta\pm\sqrt{\beta^2-8}}{2}}. \tag{4.6}$$

When $\beta\geqslant\sqrt{8}$, the four eigenvalues are real so that $u=\pm 1$ are *saddle-nodes*. For $\beta\in(-\sqrt{8},\sqrt{8})$, they are all complex with non vanishing real part. The equilibria are then called *saddle-foci*. When β passes below $-\sqrt{8}$, the eigenvalues become purely imaginary and therefore $u=\pm 1$ are *centers*.

The behaviour of the solutions of the linearization of (4.3) around the equilibria provides important informations for the solutions of the nonlinear equation. Indeed, when no eigenvalue has a vanishing real part, it is well known that under some smoothness assumptions, the nonlinear flow and the flow defined by the linearization are conjugate in a neighborhood of the equilibria, see [41]. Consequently, when $\beta\geqslant-\sqrt{8}$, the solutions of (4.3) inherit some properties of the small solutions of (4.5) when they are close to $u=\pm 1$ (with small derivatives up to third order). For example, we easily obtain a qualitative description of the shape of any heteroclinic at $\pm\infty$. Indeed, when ± 1 are saddle-nodes, the solutions of (4.5) that have limit 0 at $+\infty$ or $-\infty$ are monotone while in the saddle-foci case, they oscillate around zero.

We focus on the model equation (4.3) to present different approaches which have been considered in the literature. We assume throughout this section that β is positive. We first look at the shooting method developed by Peletier and Troy. Their results are given without proof as the arguments are not used further in this monograph. We just mention some central ideas showing again the important role of the parameter β.

As previously mentioned, Eq. (4.3) can be written

$$\frac{1}{\beta^2}u''''-u''+u^3-u=0 \tag{4.7}$$

after a suitable rescaling of u. For large β, Eq. (4.7) is a fourth-order perturbation of the Fisher–Kolmogorov equation

$$-u''+u^3-u=0$$

which can be analyzed using elementary methods. It is easily seen that $u^{\pm}(x)=\pm\tanh(\frac{x+a}{\sqrt{2}})$, $a\in\mathbb{R}$, are the only heteroclinics of the Fisher–Kolmogorov equation and these are monotone. We therefore expect that for large β the heteroclinic solutions of (4.3) are monotone. It turns out that a topological shooting method adapted to track monotone heteroclinics works fine for instance for $\beta\geqslant\sqrt{8}$. For this range of β, it is also remarkable that the uniqueness (up to translations and symmetry) of the heteroclinic solution of the Fisher–Kolmogorov equation extends to the fourth-order equation, see Note 1 below and [89].

For $|\beta| < \sqrt{8}$, the oscillatory behaviour of the solutions of (4.3) close to the equilibria makes the shooting method much more tricky. However, two families of heteroclinics can be singled out thanks to a careful analysis.

The remaining of the section is concerned with variational methods and more particularly with minimization. We expose in Section 4.2 a global minimization process. Here we develop the arguments in detail as they will be confronted with a more general framework in Section 5. We conclude our overview of the model equation (4.3) with the nice local minimization method developed by Kalies, Kwapisz and VanderVorst. Their method handles perfectly oscillatory graphs and is therefore efficient when $0 < \beta < \sqrt{8}$. In Section 4.3, we define an homotopy type which allows to consider convenient subsets for local minimization and describe the multi-transition profiles of the local minimizers. We do not present the results in detail but we emphasize that parts of the arguments are developed and used later on in Sections 6 and 7.

4.1. *A shooting method*

One of the basic tools that can be used to analyze the solutions of (4.3) is a topological shooting method developed by Peletier and Troy in [59–62], see also [63]. The main idea of a classical shooting method is to look the way solutions change with respect to initial conditions (taken as parameters) at some fixed initial point. The success of the method for second order ordinary differential equation comes from the number of parameters that is usually reduced to one. Here we reduce the number of parameters by restricting our attention to odd solutions. The reversibility of (4.3) and the oddness of the nonlinear term $u^3 - u$ allows indeed to look at the problem

$$\begin{cases} u''''(x) - \beta u''(x) + u^3(x) - u(x) = 0, \quad x \geqslant 0, \\ u(0) = u''(0) = 0, \\ \lim\limits_{x\to+\infty} \big(u, u', u'', u'''\big)(x) = (+1, 0, 0, 0). \end{cases} \tag{4.8}$$

If u solves (4.8), then the odd extension of u,

$$u^*(x) = \begin{cases} u(x) & \text{for } x \geqslant 0, \\ -u(-x) & \text{for } x < 0, \end{cases}$$

is an odd heteroclinic solution of (4.3) connecting -1 to $+1$. To find a solution of (4.8), we consider the Cauchy problem

$$\begin{cases} u''''(x) - \beta u''(x) + u^3(x) - u(x) = 0, \quad x \geqslant 0, \\ u(0) = u''(0) = 0, \\ u'(0) = \mu, \\ u'''(0) = \nu, \end{cases} \tag{S}$$

where $\mu \in \mathbb{R}^+$ and $\nu \in \mathbb{R}$. According to classical theory of ordinary differential equations, this Cauchy problem defines a unique local solution $u(\mu, \nu, \cdot)$ for every $\mu,\ \nu \in \mathbb{R}$. The shooting method then consists in finding the right initial conditions $\mu,\ \nu \in \mathbb{R}$ such that $u(\mu, \nu, \cdot)$ is globally defined and solves (4.8). A priori, we thus have to handle a two dimensional topological shooting. However, we can take benefit of a first integral to link the parameters μ and ν. In fact it is easily checked that the Hamiltonian

$$H\bigl(u,\, u',\, u'',\, u'''\bigr) = u'''u' - \frac{1}{2}u''^2 - \frac{\beta}{2}u'^2 + \frac{(u^2-1)^2}{4} \tag{4.9}$$

is constant along solutions, i.e. for every solution u of (4.3), there exists a constant E such that for all $x \in \mathbb{R}$, $H(u(x),\, u'(x),\, u''(x),\, u'''(x)) = E$. This first integral is referred to as the energy of the solution (by analogy with second order equations). Observe that any solution of (4.8) belongs to the level of energy $E = 0$. Indeed, this follows from the limit value

$$\lim_{x\to+\infty} H\bigl(u(x),\, u'(x),\, u''(x),\, u'''(x)\bigr) = 0.$$

We then infer that any solution of (4.8) satisfies

$$u'''(0) = \frac{\beta}{2}u'(0) - \frac{1}{4u'(0)}$$

taking also into account that $u'(0) \neq 0$ for such a solution. We therefore impose the conditions $\mu > 0$ and

$$\nu = \nu(\mu) := \frac{\beta}{2}\mu - \frac{1}{4\mu}$$

in the Cauchy problem (S). Summing up, the shooting method amounts to finding $\mu \in \mathbb{R}^+$ such that $u(x) := u(\mu, \nu(\mu), x)$ satisfies

$$\lim_{x\to+\infty} \bigl(u(x), u'(x), u''(x), u'''(x)\bigr) = (+1, 0, 0, 0).$$

For $\beta \geqslant \sqrt{8}$, the method is efficient to obtain a monotone heteroclinic.

THEOREM 4.1. *Let* $\beta \in [\sqrt{8}, +\infty[$. *Then there exists a monotone solution of* (4.8). *Moreover, its odd extension is a heteroclinic solution of* (4.3) *connecting* -1 *to* $+1$.

The proof goes as follows. For $\mu > 0$, we define

$$\xi(\mu) := \sup\bigl\{x > 0 \bigm| u'\bigl(\mu, \nu(\mu), \cdot\bigr) > 0 \text{ on } (0, x)\bigr\}$$

and

$$\mu^* := \sup\bigl\{\hat{\mu} \mid u\bigl(\mu, \nu(\mu), \xi(\mu)\bigr) < 1 \text{ for } \mu \in]0, \hat{\mu}[\bigr\}.$$

It turns out that $\xi(\mu^*) = +\infty$ and the orbit of $u(\mu^*, \nu(\mu^*), \cdot)$ tends to $(+1, 0, 0, 0)$ in the phase-space. We refer to [59,63] for a complete proof.

We think it is worth pointing the role of the assumption $\beta \geqslant \sqrt{8}$ in the preceding theorem. As we already mentioned, the roots of the characteristic equation associated to the linearization of (4.3) around the equilibria are real if $\beta \geqslant \sqrt{8}$. The squares of these roots are

$$\tau_\pm = \frac{\beta \pm \sqrt{\beta^2 - 8}}{2}.$$

Now observe that the linear operator $D^4 - \beta D^2 + 2I$ can be factorized as $(D^2 - \tau_+ I)(D^2 - \tau_- I)$. Letting $v = 1 - u$, Eq. (4.3) written in terms of v yields

$$v'''' - \beta v'' + 2v = v^2(3 - v). \tag{4.10}$$

Therefore, as long as $\beta \geqslant \sqrt{8}$, the solutions (v, w) of the second order system

$$\begin{cases} v'' - \tau_+ v = w, \\ w'' - \tau_- w = v^2(3 - v), \end{cases} \tag{4.11}$$

lead to solutions v of (4.10). This formulation of (4.3) as a system turns out to be very powerful to obtain estimates on v (and therefore on u) that allow to conclude that $\xi(\mu^*) = +\infty$. These estimates rely on a repeated application of the *Strong Maximum Principle* (see [65]) which can be used once we know the sign of the right hand sides in each equation of the system. The Strong Maximum Principle is also the main tool to prove the uniqueness of the heteroclinic of Theorem 4.1, see Note 1.

When $0 < \beta < \sqrt{8}$, the preceding argument involving the Maximum Principle is no more at hand. Anyway, Theorem 4.1 cannot hold in this parameter range. Indeed, as stressed in the introduction of this section, the linearization around the equilibria display oscillatory solutions so that any solution of (4.8) oscillates around $+1$ in its tail, i.e. when $x \to +\infty$. Therefore, the shooting method must now analyze carefully the location and value of the successive local extrema of $u(\mu, \nu(\mu), \cdot)$. One of the greatest difficulties when dealing with oscillatory solution graphs is to prove the convergence at infinity. The following result is the key to overcome this problem.

PROPOSITION 4.2. *Let* $\beta \geqslant 0$ *and assume* u *is a solution of* (4.3) *such that* $H(u, u', u'', u''') = 0$. *Suppose that for some* $a \in \mathbb{R}$ *and* $M > 1$,

$$\frac{1}{\sqrt{3}} \leqslant u(x) \leqslant M \quad \text{for } x > a.$$

Then

$$\lim_{x \to +\infty} \big(u, u', u'', u'''\big)(x) = (1, 0, 0, 0).$$

Basically, the proposition states that the equilibrium attracts all the solutions that stay in a strip around it. The lower bound of the strip has the particularity that the nonlinear term $u^3 - u$ is monotone increasing for all $u \geqslant \frac{1}{\sqrt{3}}$. This makes the functional

$$\mathcal{G}(u) := \frac{1}{2}u''^2 + \frac{1}{4}\big(u^2 - 1\big)^2$$

convex in the strip. This property is extensively used to prove Proposition 4.2, see [60,63].

Using sharp estimates on the critical points of $u(\mu, \nu(\mu), \cdot)$ for which we refer to [60, 63], the following can be proved. We denote respectively by ξ_k and η_k the local maxima and the local minima of the solutions of (4.8).

THEOREM 4.3. *Let β satisfy $0 < \beta < \sqrt{8}$. There exist two solutions u_1, u_2 of (4.8) that have the following properties*:

$$\frac{1}{\sqrt{3}} < u_1(\eta_k) < 1 < u_1(\xi_k) < \sqrt{2} \quad \textit{for } k = 1, 2, \ldots,$$

$$-1 < u_2(\eta_1) < 0, \quad 1 < u_2(\xi_1) < \sqrt{2} \quad \textit{and}$$

$$\frac{1}{\sqrt{3}} < u_2(\eta_k) < 1 < u_2(\xi_k) < \sqrt{2} \quad \textit{for } k = 2, 3, \ldots.$$

The odd extensions of u_1, u_2 are heteroclinic solutions of (4.3).

The solution u_1 is usually called the *principal heteroclinic* as it is monotone increasing in some interval $[-T, T]$ and it oscillates around -1 in $(-\infty, -T)$ and around $+1$ in $(T, +\infty)$. Also this heteroclinic is the first of two families of odd heteroclinic solutions which have $2n + 1$ zeros on $\mathbb{R}$. The two families differ by the amplitude of the oscillations. The first family consists of so-called *multi-transition* solutions as all the successive local extrema between the zeros are outside the region $[-1, 1]$. Thus the profiles of these solutions display $2n + 1$ jumps from -1 to $+1$ and two oscillatory tails around -1 and $+1$. In the second family, the amplitude of the oscillations is smaller than 1 so that the corresponding solutions are *single-transition* heteroclinics.

THEOREM 4.4. *Let β satisfy $0 < \beta < \sqrt{8}$. For each $n \in \mathbb{N}_0$, there exist two solutions u_1, u_2 of* (4.8) *that have the following properties*:

$$\textit{if } n \textit{ is even,} \quad \begin{cases} \textit{for } k \leqslant n/2, & u_1(\eta_k) < -1, \quad u_1(\xi_k) > 1, \\ & -1 < u_2(\eta_k) < 0 < u_2(\xi_k) < 1, \\ \textit{for } k > n/2, & 1/\sqrt{3} < u_i(\eta_k), \quad 1 < u_i(\xi_k), \quad i = 1, 2, \end{cases}$$

$$\textit{if } n \textit{ is odd,} \quad \begin{cases} \textit{for } k \leqslant (n-1)/2, & u_1(\eta_k) < -1, \quad u_1(\xi_k) > 1, \\ & -1 < u_2(\eta_k) < 0 < u_2(\xi_k) < 1, \\ \textit{for } k = (n+1)/2, & u_1(\eta_k) < -1, \quad u_1(\xi_k) > 1, \\ & -1 < u_2(\eta_k) < 0, \quad u_2(\xi_k) > 1, \\ \textit{for } k > (n+1)/2 & 1/\sqrt{3} < u_i(\eta_k), \quad u_i(\xi_k) > 1, \quad i = 1, 2. \end{cases}$$

Moreover, for all $n \geqslant 1$, $\|u_i\|_\infty < \sqrt{2}$ *and* $u_i'(0) \neq 0$ *for* $i = 1, 2$.

We refer to [60,63] for the proof.

4.2. *Minimization*

Heteroclinic solutions of (4.3) are critical points of the action functional

$$\mathcal{F}_\beta(u) = \int_{\mathbb{R}} \left(\frac{1}{2}\bigl(u''^2 + \beta u'^2\bigr) + \frac{1}{4}\bigl(u^2 - 1\bigr)^2 \right) \mathrm{d}x. \tag{4.12}$$

This functional is well defined for functions u having first and second square integrable derivatives and being such that the potential is integrable. Taking into account conditions (4.4) which are satisfied by heteroclinics connecting -1 to $+1$, we can define $\mathcal{F}_\beta$ in the space

$$\bigl\{u : \mathbb{R} \to \mathbb{R} \mid u + 1 \in H^2\bigl(\mathbb{R}^-\bigr),\ u - 1 \in H^2\bigl(\mathbb{R}^+\bigr)\bigr\}.$$

Indeed, if $u + 1 \in H^1(\mathbb{R}^-)$, then $\lim_{x \to -\infty} u(x) = -1$ see for example [22] and u is bounded in every compact interval $[-T, 0]$. A similar observation can be made on $\mathbb{R}^+$ so that we infer

$$\begin{aligned}\int_{\mathbb{R}} \frac{1}{4}\bigl(u^2 - 1\bigr)^2 \mathrm{d}x &= \int_{\mathbb{R}^-} \frac{1}{4}\bigl(u^2 - 1\bigr)^2 \mathrm{d}x + \int_{\mathbb{R}^+} \frac{1}{4}\bigl(u^2 - 1\bigr)^2 \mathrm{d}x \\ &\leqslant \frac{C}{4}\bigl(\|u + 1\|^2_{L^2(\mathbb{R}^-)} + \|u - 1\|^2_{L^2(\mathbb{R}^+)}\bigr)\end{aligned}$$

for some positive constant $C = C(\|u\|_{L^\infty(\mathbb{R})})$ and therefore $\mathcal{F}_\beta(u)$ is finite.

For $\beta \geqslant 0$, $\mathcal{F}_\beta$ is positive and hence bounded from below. The a priori simplest way to find critical points of $\mathcal{F}_\beta$ is therefore to search for minimizers. The next theorem confirms the efficiency of a minimization approach. To avoid a loss of compactness due to the invariance under translations, we look for a minimizer in the space

$$\mathcal{E} := \bigl\{u : \mathbb{R} \to \mathbb{R} \mid u(0) = 0,\ u + 1 \in H^2\bigl(\mathbb{R}^-\bigr),\ u - 1 \in H^2\bigl(\mathbb{R}^+\bigr)\bigr\}. \tag{4.13}$$

Of course, this is not restrictive.

THEOREM 4.5. *For all* $\beta \geqslant 0$, *the functional* $\mathcal{F}_\beta$ *has a global minimizer* $\varphi_\beta \in \mathcal{E}$ *which is a heteroclinic solution of* (4.3). *Furthermore, any minimizer is odd and positive in* $]0, +\infty[$.

This theorem is the analogous of Theorem 2.1. Remember that for the functional $\mathcal{J}$ of Theorem 2.1, minimizing sequences $(u_n)_n$ can be taken in such a way that $-1 \leqslant u_n \leqslant 1$. Indeed, $v_n = \sup(-1, \inf(u_n, 1))$ is still a minimizing sequence. Using similar modification arguments it is easily seen that the minimizers of $\mathcal{J}$ are monotone.

One of the first differences that we encounter when considering the functional $\mathcal{F}_\beta$ in $\mathcal{E}$, comes from the fact that these modifications which keep functions in $H^1_{\mathrm{loc}}(\mathbb{R})$ do not necessarily produce functions of class C^1 and therefore, in general, the modified functions do not belong to $H^2_{\mathrm{loc}}(\mathbb{R})$. By the way, as already mentioned, it is not true in general that minimizers of $\mathcal{F}_\beta$ in $\mathcal{E}$ are monotone. When dealing with $\mathcal{J}$, modification arguments are also used to ensure that quasi-minimizers stay close to ± 1 outside a fixed compact interval which can always be centered around zero by translation invariance.

To substitute these rather simple arguments, we take benefit of the symmetry of the functional $\mathcal{F}_\beta$. The original proof of Theorem 4.5 is due to Peletier, Troy and VanderVorst [58]. We give here a proof which is closer to Kalies and VanderVorst [43].

PROOF OF THEOREM 4.5. We introduce the spaces

$$\mathcal{E}^+ := \{u : \mathbb{R}^+ \to \mathbb{R} \mid u(0) = 0,\ u - 1 \in H^2(\mathbb{R}^+)\},$$
$$\mathcal{E}^- := \{u : \mathbb{R}^- \to \mathbb{R} \mid u(0) = 0,\ u + 1 \in H^2(\mathbb{R}^-)\}$$

and define the restricted functional $\mathcal{F}^\pm_\beta : \mathcal{E}^\pm \to \mathbb{R}$ by

$$\mathcal{F}^\pm_\beta(u) := \int_{\mathbb{R}^\pm} L(u, u', u'')\,\mathrm{d}x,$$

where $L(u, u', u'')$ is the Lagrangian defined by

$$L(u, u', u'') := \frac{1}{2}(u''^2 + \beta u'^2) + \frac{1}{4}(u^2 - 1)^2. \tag{4.14}$$

Let us consider the values

$$c := \inf_{\mathcal{E}} \mathcal{F}_\beta \quad \text{and} \quad c^\pm := \inf_{\mathcal{E}^\pm} \mathcal{F}^\pm_\beta.$$

Since $\mathcal{F}_\beta$ is symmetric, it is easily seen that for all $u^+ \in \mathcal{E}^+$, $\mathcal{F}^+_\beta(u^+) = \mathcal{F}^-_\beta(u^-)$ where $u^- \in \mathcal{E}^-$ is defined by $u^-(x) = -u^+(-x)$. Therefore, $c^+ = c^- = c/2$.

Step 1. The variational problem

$$\inf\{\mathcal{F}^+_\beta(u) \mid u \in \mathcal{E}^+\}$$

has a positive solution.

Let $(v_n)_n \subset \mathcal{E}^+$ be a minimizing sequence, i.e. $\mathcal{F}^+_\beta(v_n) \to c^+$. For each $n \geqslant 0$, we define

$$x_n := \sup\{x \geqslant 0 \mid v_n(x) = 0\}.$$

Since $\lim_{x\to+\infty} v_n(x) = 1$, $x_n < +\infty$ for all $n \geqslant 0$. We now consider the positive sequence $(v_n^+)_n \in \mathcal{E}^+$ where

$$v_n^+(x) := v_n(x + x_n)$$

for $x \geqslant 0$. We observe that

$$\int_0^{x_n} L\big(v_n, v_n', v_n''\big)\,\mathrm{d}x \geqslant 0$$

so that $\mathcal{F}_\beta^+(v_n^+) \leqslant \mathcal{F}_\beta^+(v_n)$ which implies that $(v_n^+)_n$ is also a minimizing sequence for $\mathcal{F}_\beta^+$.

As the sequence $\mathcal{F}_\beta^+(v_n^+)$ is uniformly bounded, we deduce a uniform estimate for $\|v_n^+ - 1\|_{H^2(\mathbb{R}^+)}$. Indeed, the L^2-bounds for $(v_n^+)'$ and $(v_n^+)''$ follow easily from the bound on $\mathcal{F}_\beta^+(v_n^+)$ while we infer from the positivity of v_n^+ that

$$\int_0^{+\infty} \frac{(v_n^+ - 1)^2}{4}\,\mathrm{d}x \leqslant \int_0^{+\infty} \frac{(v_n^{+2} - 1)^2}{4}\,\mathrm{d}x \leqslant \mathcal{F}_\beta^+\big(v_n^+\big).$$

We now deduce that going to a subsequence if necessary, there exists $v^+ \in H^2(\mathbb{R}^+) + 1$ such that

$$v_n^+ - 1 \overset{H^2(\mathbb{R}^+)}{\rightharpoonup} v^+ - 1$$

and

$$v_n^+ \xrightarrow{C^1_{\mathrm{loc}}(\mathbb{R}^+)} v^+.$$

As the two first terms in $\mathcal{F}_\beta^+$ are the square of seminorms and Fatou's Lemma is applicable to the last one, it follows that

$$\mathcal{F}_\beta^+\big(v^+\big) \leqslant \liminf_{n\to+\infty} \mathcal{F}_\beta^+\big(v_n^+\big) = c^+.$$

As the convergence is uniform on compact intervals, we conclude that $v^+(0) = 0$ so that $v^+ \in \mathcal{E}^+$ and $\mathcal{F}_\beta^+(v^+) = c^+$. Observe that v^+ is positive on $]0, +\infty[$ otherwise we could proceed as above to construct a positive function having smaller action.

Step 2. If $v \in \mathcal{E}^+$ is such that $(\mathcal{F}_\beta^+)'(v) = 0$, then $v''(0) = 0$, $v^* \in \mathcal{E}$ defined by

$$v^*(x) := \begin{cases} v(x) & \text{if } x \geqslant 0, \\ -v(-x) & \text{if } x < 0, \end{cases}$$

is a minimizer of $\mathcal{F}_\beta$ in $\mathcal{E}$ and v^* is a heteroclinic solution of (4.3).

We first compute

$$\big(\mathcal{F}_\beta^+\big)'(v)(h) = \int_0^{+\infty} \big(v''h'' + \beta v'h' + \big(v^3 - v\big)h\big)\,\mathrm{d}x \tag{4.15}$$

for all $h \in H^2(\mathbb{R}^+) \cap H_0^1(\mathbb{R}^+)$. Starting with $h \in C_c^2(\mathbb{R}^+)$ and using Du Bois–Reymond Lemma, we easily find that in fact $v \in C^4(\mathbb{R}^+)$ and v solves (4.3) for $x \geqslant 0$. As Eq. (4.3) expresses v'''' in terms of v'' and $v-1$, we deduce that $v'''' \in L^2(\mathbb{R}^+)$. Indeed, $v'' \in L^2(\mathbb{R}^+)$ and

$$\int_0^{+\infty} \big(v^3(x) - v(x)\big)^2 \,\mathrm{d}x \leqslant \big(\|v\|_\infty^2 + \|v\|_\infty\big)\|v-1\|_{L^2}^2 < \infty.$$

It now follows by interpolation that

$$\|v'''\|_{L^2}^2 \leqslant C\big(\|v''\|_{L^2} + \|v''''\|_{L^2}\big) < \infty.$$

Hence $v - 1 \in H^4(\mathbb{R}^+)$. Observe also that the L^2-integrability of the derivatives implies that

$$\lim_{x\to+\infty} v(x) = +1 \quad \text{and} \quad \lim_{x\to+\infty} v^{(n)}(x) = 0 \quad \text{for } n = 1, 2, 3. \tag{4.16}$$

Integrating (4.15) by parts, we obtain for all $h \in H^2(\mathbb{R}^+) \cap H_0^1(\mathbb{R}^+)$,

$$\big[v''h'\big]_0^{+\infty} - \big[v'''h\big]_0^{+\infty} - \beta\big[v'h\big]_0^{+\infty} = 0$$

as

$$\int_0^{+\infty} \big(v'''' - \beta v'' + v^3 - v\big)(x)h(x)\,\mathrm{d}x = 0.$$

Taking (4.16) into account, we now deduce that

$$v''(0)h'(0) = 0$$

for all $h \in H^2(\mathbb{R}^+) \cap H_0^1(\mathbb{R}^+)$ which of course implies that $v''(0) = 0$. The function $v^* : \mathbb{R} \to \mathbb{R}$ defined by

$$v^*(x) = \begin{cases} v(x) & \text{if } x \geqslant 0, \\ -v(-x) & \text{if } x < 0, \end{cases}$$

is therefore of class C^4 and straightforward arguments allow to conclude that v^* is a critical point of $\mathcal{F}_\beta$ which is a heteroclinic solution of (4.3), actually of class C^∞. Also, $\mathcal{F}_\beta(v^*) = 2\mathcal{F}_\beta^+(v) = 2c^+ = c$ so that v^* is a minimizer of $\mathcal{F}_\beta$ in $\mathcal{E}$.

Step 3. If $u \in \mathcal{E}$ minimizes $\mathcal{F}_\beta$, then u is odd.

Let us write $u^\pm = u_{|\mathbb{R}^\pm}$. As $\mathcal{F}_\beta(u) = c$, we have $\mathcal{F}_\beta^+(u^+) = \mathcal{F}_\beta^-(u^-) = c/2$ otherwise the odd extension of u^+ or u^- would have a lower action than c. From Step 2, we know that $u(0) = u''(0) = 0$. Hence $v^+(x) := -u^-(-x)$ satisfies $\mathcal{F}_\beta^+(v^+) = c^+$ and $v^+(0) = (v^+)''(0) = 0$. Thus both u^+ and v^+ are minimizers of $\mathcal{F}_\beta^+$ in $\mathcal{E}^+$. As

$(v^+)'(0) = (u^-)'(0) = (u^+)'(0)$ and $(v^+)'''(0) = (u^-)'''(0) = (u^+)'''(0)$, the functions v^+ and u^+ solve the same Cauchy problem

$$\begin{aligned}
&u''''(x) - \beta u''(x) + u^3(x) - u(x) = 0, \quad x \geqslant 0,\\
&u(0) = 0, \quad u'(0) = \big(u^+\big)'(0),\\
&u''(0) = 0, \quad u'''(0) = \big(u^+\big)'''(0).
\end{aligned}$$

By uniqueness, this implies $u^+(x) = v^+(x)$ for all $x \in \mathbb{R}^+$, i.e. $u^+(x) = -u^-(-x)$ for all $x \in \mathbb{R}^+$. □

4.3. *Homotopy classes of multi-transition solutions*

When $\beta < \sqrt{8}$, the equilibrium solution ± 1 of (4.3) are saddle-foci. It is known that heteroclinic connections between such kind of equilibria can exhibit a complex structure, see [23, 31,60]. In [43], Kalies and VanderVorst construct for (4.3) so-called *multi-bump* solutions i.e solutions with multiple oscillations separated by large distances. The usual methods used to obtain such solutions are rather tricky and require a careful study of the stable and unstable manifolds or a certain kind of nondegeneracy condition on a primary connection whose well separated copies are then glued together, see [23,28,79]. In [42], Kalies, Kwapisz and VanderVorst introduce a direct method to find multi-transition solutions. As we already mentioned, the term multi-transition refers to the fact that the graph of such solutions consists of multiple jumps from one equilibrium to the other. One jump is then called a transition. Also such solutions are qualitatively different from multi-bump solutions as the distance between two successive transition is not necessarily large. The method of Kalies et al. consists in minimizing the action functional (4.12) in specific subspaces of functions having the desired number of transitions.

When projected in the configuration plane (u, u'), a heteroclinic orbit yields a curve connecting the points $(\pm 1, 0)$. Choosing two oriented loops e_1 and e_2 around respectively $(-1, 0)$ and $(+1, 0)$ (see Fig. 2), an homotopy type can be associated to any curve connecting $(\pm 1, 0)$ (see the precise definition below). This homotopy type records the number of transitions between these points and the oscillations around them between the transitions. Hence, every orbit connecting $(-1, 0)$ to $(+1, 0)$ can be represented by a word of the form

$$e_1^{\theta_{2m}} \cdot e_2^{\theta_{2m-1}} \cdot \cdots \cdot e_1^{\theta_2} \cdot e_2^{\theta_1},$$

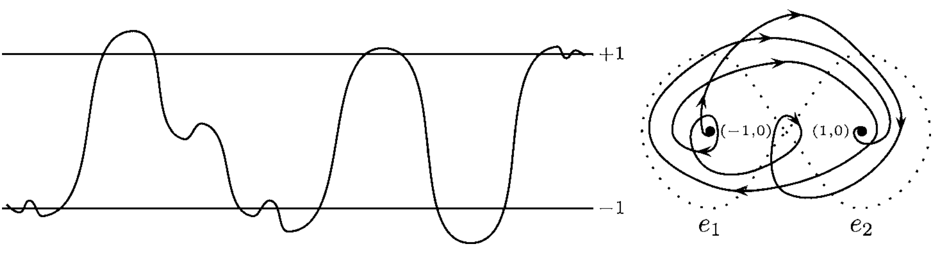

Fig. 2. An orbit with homotopy type $e_1 e_2 e_1^2 e_2$.

where $\theta(u) = (\theta_1, \dots, \theta_{2m}) \in \mathbb{N}^{2m}$. The vector $\theta(u)$ is called the *winding* vector associated to u. Observe that the word starts with the first visit at $(+1, 0)$ and stops recording after the last visit around $(-1, 0)$. Also the vector $g(u) = 2\theta(u)$ contains exactly the number of crossings that u makes with ± 1 between the transitions. The vector $g = 0$ is therefore associated to functions with a single transition. For each vector $g \in 2\mathbb{N}^{2m} \cup \{0\}$, the homotopy class $M(g)$ consisting of functions of $\mathcal{E}$ having winding vector $g/2$. The following more precise definition is introduced in [42].

DEFINITION 4.6. A function $u \in \mathcal{E}$ is in $M(g)$ if there are nonempty sets $\{A_i\}_{i=0}^{2m+1}$ such that

(i) $u^{-1}(\pm 1) = \bigcup_{i=0}^{2m+1} A_i$,
(ii) $\#A_i = g_i$ for $i = 1, \dots, 2m$,
(iii) $\max A_i < \min A_{i+1}$ for $i = 0, \dots, 2m$,
(iv) $u(A_i) = (-1)^{i+1}$,
(v) $\{\max A_0\} \cup (\bigcup_{i=1}^{2m} A_i) \cup \{\min A_{2m+1}\}$ consists of transverse crossings of ± 1.

Under these conditions $M(g)$ is an open subset of $\mathcal{E}$. As the functional $\mathcal{F}_\beta$ is positive, we can define

$$\inf_{u \in M(g)} \mathcal{F}_\beta(u). \tag{4.17}$$

If the infimum is achieved by a function in the interior of $M(g)$, then a local minimizer of $\mathcal{F}_\beta$ with the corresponding properties solves the Euler–Lagrange equation (4.3). The next theorem is a particular case of Theorem 1.3 in [42].

THEOREM 4.7. *Let* $0 < \beta < \sqrt{8}$. *Then for all* $g \in 2\mathbb{N}^{2m} \cup \{0\}$, *the functional* $\mathcal{F}_\beta$ *defined by* (4.12) *has a local minimizer* u_g *in the homotopy class* $M(g)$. *Moreover, the function* u_g *is a heteroclinic solution of* (4.3) *displaying* $2m + 1$ *transitions between* ± 1.

The proof of Theorem 4.7 is carried out in [42]. The main difficulty is to show that minimizing sequences in $M(g)$ have weak limits in the interior of $M(g)$. Indeed, minimizing sequences can approach the boundary of $M(g)$ so that the limit function could gain or lose complexity. For example, tangential crossings of ± 1 could appear due to a coalescence of two or more crossings or to a new spurious oscillation around one equilibrium. The oscillatory behaviour of solutions in a neighborhood of a saddle-focus equilibrium plays then a crucial role to control the minimizing sequences. Efficient tools were developed by Kalies et al. to adjust functions of the boundary of $M(g)$. Basically these tools rely on a cut and paste technique which allows to delete spurious oscillations or replace pieces of functions tangent to ± 1 with pieces of small oscillating orbits around $(\pm 1, 0, 0, 0)$ in the phase-space.

Another source of troubles in the minimization process comes from a possible lack of compactness when passing to a weak limit. Indeed the distance between two transitions or two crossings of either -1 or $+1$ could grow to infinity. Here again the oscillatory properties of the orbits close to a saddle-focus prevent from these losses of complexity in the limit.

4.4. *Notes and further comments*

1. As already mentioned, in case $\beta \in [\sqrt{8}, +\infty[$, the heteroclinic solution obtained in Theorem 4.1 is unique (up to translation and symmetry). The first result in this direction is due to Peletier and Troy [59]. They prove that the heteroclinic obtained via the shooting method is unique in the class of monotone antisymmetric functions and they conjecture that it is actually unique in the class of all functions. Kwapisz [47] and van den Berg [89] have then confirmed the conjecture. The proof of Kwapisz relies on the use of a twist-map while the arguments of van den Berg are based on the analysis of the phase-space and more precisely of its projection into the configuration plane (u, u'). The analysis of van den Berg applies to the model equation

$$u'''' - \beta u'' + f'(u) = 0, \tag{4.18}$$

where f is a double-well potential of class C^2. Considering the set of bounded functions

$$\mathcal{B}(a,b) := \big\{u \in C^4(\mathbb{R}) \bigm| u(x) \in [a,b] \text{ for all } x \in \mathbb{R}\big\},$$

and the value

$$\omega(a,b) = \max\Big\{0, \max_{u\in[a,b]} -f''(u)\Big\},$$

his key result states that when $\beta \geqslant 2\sqrt{\omega(a,b)}$, bounded solutions of (4.18) in $\mathcal{B}(a,b)$ do not cross in the configuration plane (u,u'). Observing then that for $\beta \geqslant \sqrt{8}$, any bounded solution u of (4.3) satisfies $\|u\|_\infty \leqslant 1$, he deduces that the uniqueness property in the configuration plane holds for the parameter range $\beta \geqslant \sqrt{8}$. The a priori bound is obtained by applying the maximum principle twice to the factorization (4.11). The uniqueness of the heteroclinic solution then follows from the energy ordering of the bounded solutions in the configuration plane (u,u'). As stressed in Section 4.1, the Hamiltonian

$$H\big(u,u',u'',u'''\big) = u'''u' - \frac{1}{2}u''^2 - \frac{\beta}{2}u'^2 + f(u)$$

is constant along solutions. It turns out that for $\beta \geqslant 2\sqrt{\omega(a,b)}$ and solutions of (4.18) in $\mathcal{B}(a,b)$, the energy $E = H(u,\, u',\, u'',\, u''')$ is a parameter that orders the solutions in the configuration plane.

It is worth mentioning that the results of [89] also imply that the unique heteroclinic of Theorem 4.1 is asymptotically stable in the space of bounded uniformly continuous functions.

2. The global minimization approach of Section 4.2 can be extended to the functional

$$\mathcal{J}(u) := \int_{-\infty}^{\infty} \Big(\frac{1}{2}\big(u''^2 + g(u)u'^2\big) + f(u)\Big)\,\mathrm{d}x,$$

where $g:\mathbb{R}\to\mathbb{R}$ is a positive function and $f:\mathbb{R}\to\mathbb{R}$ is a double well potential with nondegenerate minima at the same level of energy, see Section 5. If f and g are even then the equivalent of Theorem 4.5 holds. When this is not the case, the conclusion that any minimizer is odd is false and we cannot ensure that minimizers are still single-transition solutions.

3. The results of Section 4.3 hold in a more general framework. The potential $\frac{(u^2-1)^2}{4}$ may be replaced by a function $f\in C^2(\mathbb{R})$ that has exactly two nondegenerate global minima at $u=\pm 1$ and grows superquadratically at $\pm\infty$. If the parameter β satisfies $\beta^2<4f''(\pm 1)$ then $u=\pm 1$ are saddle-focus equilibria for the equation

$$u'''' - \beta u'' + f'(u) = 0.$$

If f is even then the equivalent of Theorem 4.7 holds, while without this symmetry assumption it is not clear that the infima are attained in the interior of each homotopy class. However, when $g_i=2$ for all i or if the g_i's are large enough (i.e. the profile is then similar to multi-bump solutions) then local minimizers exist in the corresponding class $M(g)$, see [42].

4. Not much is known about the role of the heteroclinic solutions for the evolution problem

$$\begin{cases} \dfrac{\partial u}{\partial t} + \dfrac{\partial^4 u}{\partial x^4} - \beta\dfrac{\partial^2 u}{\partial x^2} + u^3 - u = 0, & 0<x<L,\ t>0,\\ u(t,0) = u(t,L) = 0, & t>0,\\ \dfrac{\partial^2 u}{\partial x^2}(t,0) = \dfrac{\partial^2 u}{\partial x^2}(t,L) = 0, & t>0,\\ u(0,x) = u_0(x), & 0<x<L. \end{cases}$$

When $\beta\geqslant\sqrt{8}$, the stability of the heteroclinic has been proved by van den Berg [89].

Another class of solutions, namely travelling wave solutions, is important for the dynamics of the evolution equation. These solutions are waves that evolve at constant speed. Thus they can be written $u(t,x)=U(x-ct)$ for some constant c and solve the equation

$$U'''' - \beta U'' - cU' + f'(U) = 0.$$

For this last equation, the heteroclinic solutions connecting -1 to $+1$ or 0 to -1 or $+1$ are of particular interest. The problem of existence of such solutions is not completely solved. Partial results exist for similar models with an asymmetric nonlinear term like $f_a'(u)=(u+a)(u^2-1)$, $a\neq 0$. The case $a=0$ can also be treated when dealing with heteroclinics connecting 0 to -1 or $+1$. For further details, we refer to [75,88,90].

5. It was observed in [58] that the arguments used in the proof of Theorem 4.5 can be carried over to treat sixth order bistable equations of the form

$$u^{(6)} + Au^{(4)} + Bu^{(2)} + u - u^3 = 0$$

provided that $A^2 < 4B$. The associated functional is then coercive and weakly lower-semicontinuous.

5. Sign changing Lagrangians

The success of the arguments of Section 4.2 depends on the positivity and the symmetry of the Lagrangian

$$L(u, u', u'') = \frac{1}{2}\big(u''^2 + \beta u'^2\big) + \frac{1}{4}\big(u^2 - 1\big)^2.$$

The symmetry of the potential allows to consider a restricted functional on $\mathbb{R}^+$ which makes the minimization process very simple. However it is easily seen that a more tedious proof works fine without exploiting the symmetry of the functional. On the other hand, the positivity of the Lagrangian seems much more crucial. Indeed, it gives a simple lower bound on the functional. Another great advantage of the Lagrangian L is that the potential $f(u) = \frac{1}{4}(u^2 - 1)^2$ is superquadratic at $\pm\infty$ and has nondegenerate minima i.e. $f''(\pm 1) \neq 0$. This last property implies that for u close to $+1$ (respectively -1), $f(u)$ behaves like the square of the L^2-norm of $u - 1$ (respectively $u + 1$).

In this section, we consider a larger class of Lagrangians

$$L_g\big(u, u', u''\big) := \frac{1}{2}\big(u''^2 + g(u)u'^2\big) + f(u). \tag{5.1}$$

Here the function g is not assumed to be positive and f is a positive two-well potential with bottoms at ± 1. We consider in a convenient space (which is made precise below) the functional

$$\mathcal{F}(u) := \int_{-\infty}^{+\infty} \left(\frac{1}{2}\big(u''^2 + g(u)u'^2\big) + f(u)\right) \mathrm{d}x \tag{5.2}$$

whose Euler–Lagrange equation is given by

$$u'''' - g(u)u'' - \frac{1}{2}g'(u)u'^2 + f'(u) = 0. \tag{5.3}$$

The main idea is then to impose a condition on g to ensure a lower bound on the action $\mathcal{F}(u)$.

The results of Section 5.1 are based on [20,37]. The main assumption is as follows:

(C1) there exist a function $\tilde{g} \in C(\mathbb{R})$ and some $k < 1$ such that for all $u \in \mathbb{R}$,

$$g(u) \geqslant \tilde{g}(u) \quad \text{and } \big|\tilde{G}(u)\big| \leqslant k\sqrt{8f(u)},$$

where

$$\tilde{G}(u) := \int_0^u \tilde{g}(s)\,\mathrm{d}s.$$

This condition can be seen as a good balance between the possible negativity of g and the positivity of the potential. Though assumption (C1) allows g to take negative values, it rules out a negative constant. Indeed, $\tilde{g}$ must satisfy

$$\int_{-1}^{0} \tilde{g}(s)\,\mathrm{d}s = \int_{0}^{+1} \tilde{g}(s)\,\mathrm{d}s = 0.$$

Some regularity assumptions have to be made on f and g but it should be stressed that the approach does not require the nondegeneracy of the equilibria ±1 as implicitly assumed when considering the model potential in $\mathcal{F}_\beta$. This rather weak assumption on the potential does not allow to define the functional $\mathcal{F}$ in an affine translate of $H^2(\mathbb{R})$ so that a slight modification of the functional settings has to be performed.

Section 5.2 reviews the results of [19]. Here more assumptions are in order but on the other hand g can be negative everywhere. Mainly, we only deal with symmetric functionals with an even potential having nondegenerate minima. Also, we do assume that the functional is bounded from below. We prove that this is the case when g^- is small.

5.1. *Functionals with sign changing acceleration coefficient*

We consider a two-well potential $f \in C^1(\mathbb{R})$ such that

(C2) for some $0 < a < 1$ and $\alpha > 0$,

$$\frac{f(u)}{(u-1)^2} \leqslant \alpha, \quad \text{for } |u-1| < a,$$
$$\frac{f(u)}{(u+1)^2} \leqslant \alpha, \quad \text{for } |u+1| < a;$$

(C3) $f(u) = 0$ if and only if $u = \pm 1$;

(C4) $f(u) \geqslant 0$ for all $u \in \mathbb{R}$ and

$$\liminf_{|u|\to\infty} f(u) > 0.$$

We also assume that $g \in C^1(\mathbb{R})$ satisfies (C1).

Notice that the assumption (C2) is automatically satisfied when ±1 are nondegenerate minima. In this case, if f is of class C^2 in a neighborhood of ±1, $g(\pm 1) < 0$ or (C1) holds with $g = \tilde{g}$ then ±1 are saddle-foci. Indeed, by l'Hospital's rule, we obtain

$$\frac{\tilde{g}^2(\pm 1)}{4f''(\pm 1)} = \lim_{u\to\pm 1} \frac{\tilde{G}^2(u)}{8f(u)} < 1,$$

so that

$$g(\pm 1)^2 \leqslant \tilde{g}(\pm 1)^2 < 4f''(\pm 1).$$

In order to find a solution u of (5.3) that satisfies

$$\lim_{x\to\pm\infty} u(x) = \pm 1,$$

we minimize the functional $\mathcal{F}$ in a convenient functional space. As the assumptions on f are quite weak and g can vanish close to ± 1, a function u that satisfies $\mathcal{F}(u) < \infty$ does not necessarily belong to an affine translate of $H^2(\mathbb{R})$ as it was the case for heteroclinic solutions of (4.3). In fact it is sufficient to search a minimizer of $\mathcal{F}$ in the set

$$\mathcal{H} := \Big\{ u \in C^1(\mathbb{R}),\ u'' \in L^2(\mathbb{R}),\ u' \in L^\infty(\mathbb{R}) \text{ and } \lim_{x\to\pm\infty} u(x) = \pm 1 \Big\}. \tag{5.4}$$

We first observe that under assumption (C1), the functional $\mathcal{F}$ is bounded from below in $\mathcal{H}$. This justifies our minimization procedure.

LEMMA 5.1. *If $f, g \in C(\mathbb{R})$ satisfy* (C1), *then there exists a constant $s > 0$ such that for all $u \in \mathcal{H}$*

$$\mathcal{F}(u) \geqslant s \int_{-\infty}^{+\infty} \left(\frac{u''^2}{2} + f(u) \right) \mathrm{d}x.$$

PROOF. Let k be given by the assumption (C1). For $c \in\,]k, 1[$, we compute

$$\begin{aligned} \mathcal{F}(u) &\geqslant \int_{-\infty}^{+\infty} \left(\frac{1}{2}\big(u''^2 + \tilde{g}(u)u'^2\big) + f(u) \right) \mathrm{d}x \\ &\geqslant \int_{-\infty}^{+\infty} \left(\frac{1}{2}\big(1 - c^2\big)u''^2 + \frac{1}{2}\left(cu'' - \frac{\tilde{G}(u)}{2c}\right)^2 + \left(f(u) - \frac{\tilde{G}(u)^2}{8c^2} \right) \right) \mathrm{d}x, \end{aligned}$$

where we have performed an integration by parts and used the fact that u' is bounded and $\tilde{G}(u(\pm\infty)) = \tilde{G}(\pm 1) = 0$ to obtain

$$-\int_{-\infty}^{+\infty} \tilde{G}(u)u''\,\mathrm{d}x = \int_{-\infty}^{+\infty} \tilde{g}(u)u'^2\,\mathrm{d}x.$$

Hence by our assumption, we obtain the inequality

$$\mathcal{F}(u) \geqslant \int_{-\infty}^{+\infty} \left(\frac{1}{2}\big(1 - c^2\big)u''^2 + \left(1 - \frac{k^2}{c^2}\right) f(u) \right) \mathrm{d}x$$

so that the conclusion follows. □

We now state the main theorem of the section.

THEOREM 5.2. *Suppose that $f, g \in C^1(\mathbb{R})$ satisfy* (C1)–(C4). *Then, there exists a minimizer u of $\mathcal{F}$ in $\mathcal{H}$ which is a solution of* (5.3).

To prove this theorem, we need sharp estimates on minimizing sequences. The key arguments are summarized in the next proposition.

PROPOSITION 5.3. *Suppose that* $f, g \in C^1(\mathbb{R})$ *satisfy* (C1)–(C4). *Then there exist* $L > 0$, $T > 0$ *and a sequence* $(u_n)_{n\in\mathbb{N}} \subset \mathcal{H}$ *such that* $\mathcal{F}(u_n) \to \inf_{\mathcal{H}} \mathcal{F}$ *and for all* $n \in \mathbb{N}$,

(i) $\|u_n\|_{C^1} \leqslant L$,

(ii) $|u_n(x) + 1| \leqslant a$ *for all* $x \leqslant -T$ *and* $|u_n(x) - 1| \leqslant a$ *for all* $x \geqslant T$.

Observe that the first property of the minimizing sequence $(u_n)_n$ allows to choose a converging subsequence in C^1_{loc}. The second property then prevents from the lack of compactness of the functional space $\mathcal{H}$ due to the invariance of $\mathcal{F}$ under translations. The proof of Theorem 5.2 easily follows from Proposition 5.3.

PROOF OF THEOREM 5.2. Let $(u_n)_n \subset \mathcal{H}$ be a minimizing sequence satisfying the conclusions of Proposition 5.3.

Step 1. *Convergence.* According to Lemma 5.1, the sequence u_n'' is uniformly bounded in L^2. Together with the uniform bound on u_n in C^1 (property (i) of the minimizing sequence), this implies that $(u_n)_n$ has a subsequence (still written $(u_n)_n$ for simplicity) such that for some function u

$$u_n \xrightarrow{C^1_{\text{loc}}(\mathbb{R})} u, \quad u_n'' \overset{L^2(\mathbb{R})}{\rightharpoonup} u''.$$

We now infer from Lemma 5.1 and Fatou's Lemma that

$$\int_0^{+\infty} f\big(u(x)\big)\,\mathrm{d}x < +\infty. \tag{5.5}$$

Step 2. $u \in \mathcal{H}$. Observe first that $u' \in L^\infty(\mathbb{R})$. Indeed, as u_n' converges uniformly to u' on every compact subset of $\mathbb{R}$, it follows from the uniform bound on $\|u_n'\|_\infty$ that u' is bounded.

We next prove that

$$\lim_{x\to+\infty} u(x) = 1.$$

From the uniform convergence on compact sets, it is clear that $|u(x) - 1| \leqslant a$ for $x \geqslant T$. We therefore deduce that

$$1 - a \leqslant \liminf_{x\to+\infty} u(x) \leqslant \limsup_{x\to+\infty} u(x) \leqslant 1 + a.$$

Assume by contradiction that $\limsup_{x\to+\infty} u(x) > 1$. This means that for some $0 < \varepsilon < a$, there exist infinitely many disjoint intervals $[a_i, b_i] \subset \mathbb{R}^+$, $i \in \mathbb{N}$ such that

$$1 + \frac{\varepsilon}{2} \leqslant u(x) \leqslant 1 + \varepsilon \quad \text{for all } x \in [a_i, b_i].$$

We can suppose without loss of generality that $u(b_i) - u(a_i) = \pm\varepsilon/2$. As $\|u'\|_\infty \leqslant L$, we infer that

$$\frac{\varepsilon}{2} = \left|u(b_i) - u(a_i)\right| = \left|\int_{a_i}^{b_i} u'(s)\,\mathrm{d}s\right| \leqslant L(b_i - a_i)$$

which implies that

$$(b_i - a_i) \geqslant \frac{\varepsilon}{2L}.$$

Now, let $m_\varepsilon > 0$ be such that $f(u) \geqslant m_\varepsilon$ for all $u \in [1 + \frac{\varepsilon}{2}, 1 + \varepsilon]$. We then compute

$$\int_0^{+\infty} f\big(u(x)\big)\,\mathrm{d}x \geqslant \sum_{i=0}^{\infty} \int_{a_i}^{b_i} f\big(u(x)\big)\,\mathrm{d}x \geqslant \sum_{i=0}^{\infty} \frac{\varepsilon\, m_\varepsilon}{2L} = +\infty$$

which contradicts (5.5). If $\liminf_{x\to+\infty} u(x) < 1$, we derive the same contradiction so that

$$\liminf_{x\to+\infty} u(x) = \limsup_{x\to+\infty} u(x) = 1.$$

As we can argue similarly if $\limsup_{x\to-\infty} u(x) > -1$ or $\liminf_{x\to-\infty} u(x) < -1$, we also infer that

$$\lim_{x\to-\infty} u(x) = -1.$$

Summing-up, we come to the conclusion that $u \in \mathcal{H}$.
Conclusion. To see that u is a minimizer of $\mathcal{F}$, arguing as in Lemma 5.1 we compute

$$\begin{aligned}
\mathcal{F}(u_n) &= \int_{-\infty}^{\infty} \left(\frac{1}{2}\big(u_n''^2 + \tilde{g}(u_n)u_n'^2\big) + f(u_n)\right)\mathrm{d}x \\
&\quad + \int_{-\infty}^{\infty} \frac{1}{2}\big(g(u_n) - \tilde{g}(u_n)\big)u_n'^2\,\mathrm{d}x \\
&= \int_{-\infty}^{\infty} \frac{1}{2}\left(u_n'' - \frac{\tilde{G}(u_n)}{2}\right)^2 \mathrm{d}x + \int_{-\infty}^{\infty} \left(f(u_n) - \frac{\tilde{G}(u_n)^2}{8}\right)\mathrm{d}x \\
&\quad + \int_{-\infty}^{\infty} \frac{1}{2}\big(g(u_n) - \tilde{g}(u_n)\big)u_n'^2\,\mathrm{d}x.
\end{aligned} \tag{5.6}$$

As all the terms of the right-hand side are positive, we deduce that

$$\sup_{n\in\mathbb{N}} \left\| u_n'' - \frac{\tilde{G}(u_n)}{2} \right\|_{L^2} < +\infty.$$

Going to a subsequence if necessary, we may assume that $u_n'' - \frac{\tilde{G}(u_n)}{2}$ converges weakly in L^2 and therefore

$$\int_{-\infty}^{\infty} \frac{1}{2}\left(u'' - \frac{\tilde{G}(u)}{2}\right)^2 \mathrm{d}x \leqslant \liminf_{n\to\infty} \int_{-\infty}^{\infty} \frac{1}{2}\left(u_n'' - \frac{\tilde{G}(u_n)}{2}\right)^2 \mathrm{d}x.$$

Now observe that the integrands of the two last terms of (5.6) converge for each $x \in \mathbb{R}$ and are positive. Fatou's lemma is then applicable and we obtain

$$\int_{-\infty}^{+\infty} \left(f(u) - \frac{\tilde{G}(u)^2}{8}\right) \mathrm{d}x \leqslant \liminf_{n\to\infty} \int_{-\infty}^{+\infty} \left(f(u_n) - \frac{\tilde{G}(u_n)^2}{8}\right) \mathrm{d}x$$

and

$$\int_{-\infty}^{+\infty} \frac{1}{2}\big(g(u) - \tilde{g}(u)\big)u'^2 \,\mathrm{d}x \leqslant \liminf_{n\to\infty} \int_{-\infty}^{+\infty} \frac{1}{2}\big(g(u_n) - \tilde{g}(u_n)\big)u_n'^2 \,\mathrm{d}x.$$

From Step 2, we know that $u \in \mathcal{H}$. The equality (5.6) thus also holds with u_n replaced by u and we finally deduce that

$$\mathcal{F}(u) \leqslant \liminf_{n\to\infty} \mathcal{F}(u_n) = \inf_{\mathcal{H}} \mathcal{F}$$

which by Step 2 implies

$$\mathcal{F}(u) = \inf_{\mathcal{H}} \mathcal{F}.$$

This completes the proof. □

We devote the remaining of the section to the proof of Proposition 5.3. We first need some preliminary results. Our next purpose is to complete the functional settings by proving that the first derivative of any function $u \in \mathcal{H}$ that satisfies $\mathcal{F}(u) < \infty$, vanishes at $\pm\infty$. To this aim, we next state the following useful estimate.

LEMMA 5.4. *Given an interval* $[a, b] \subset \mathbb{R}$ *and a function* $u \in H^2(a, b)$ *such that* $u(a) = A$, $u(b) = B$, $u'(a) = A_1$, $u'(b) = B_1$, *the following inequality holds*:

$$\int_a^b u''^2 \,\mathrm{d}x \geqslant \frac{4}{b-a}\left((B_1 - A_1)^2 + 3\left(\frac{B-A}{b-a} - A_1\right)\left(\frac{B-A}{b-a} - B_1\right)\right),$$

and equality holds if and only if u is a third degree polynomial.

PROOF. Denote by P the third degree polynomial that coincides in H^2 with u at points a and b. Writing $u = P + w$, we compute

$$\int_a^b u''^2 \,\mathrm{d}x = \int_a^b P''^2 \,\mathrm{d}x + \int_a^b w''^2 \,\mathrm{d}x + 2\int_a^b P''w'' \,\mathrm{d}x. \tag{5.7}$$

Integrating $P''w''$ by parts and using the fact that $w(a) = w(b) = w'(a) = w'(b) = 0$, we see that the last integral in (5.7) is actually zero. We thus obtain the inequality

$$\int_a^b u''^2 \,\mathrm{d}x \geqslant \int_a^b P''^2 \,\mathrm{d}x$$

and the conclusion now follows by computing the integral of P''^2. □

LEMMA 5.5. *Let $u \in \mathcal{H}$ be such that $\mathcal{F}(u) < \infty$. Then*

$$\lim_{|x|\to\infty} u'(x) = 0.$$

PROOF. Let $\varepsilon > 0$ and $u \in \mathcal{H}$ be given. Suppose by contradiction that our conclusion is false. Assume for example that $u'(x_n) \geqslant \varepsilon$ for some sequence $x_n \to +\infty$, $n \in \mathbb{N}$. Let $\delta > 0$ be such that

$$\delta < \frac{s\varepsilon^3}{16\mathcal{F}(u)},$$

where s is given by Lemma 5.1. Then, as $\lim_{x\to+\infty} u(x) = 1$, there exists $R > 0$ such that for all $x \geqslant R$, $|u(x) - 1| \leqslant \delta/2$. Let $x_0 > R$ be such that $u'(x_0) = \varepsilon$.

We claim that we can find $x_1 > x_0$ such that $u'(x_1) = \varepsilon/2$, $u(x_1) \leqslant u(x_0) + \delta$ and $x_1 - x_0 \leqslant 2\delta/\varepsilon$. Indeed, if $x > x_0$, we have $|u(x) - u(x_0)| \leqslant \delta$ and as $\lim_{x\to+\infty} u(x) = 1$, there exists $x > x_0$ such that $u'(x) \leqslant \varepsilon/2$. We can therefore choose x_1 such that $u'(x) \geqslant \varepsilon/2$ for all $x \in [x_0, x_1]$. We then have

$$\frac{\varepsilon}{2}(x_1 - x_0) \leqslant \int_{x_0}^{x_1} u'(s)\,\mathrm{d}s = u(x_1) - u(x_0) \leqslant \delta.$$

Now, letting $m = \frac{u(x_1)-u(x_0)}{x_1-x_0}$, we infer from Lemma 5.4 that

$$\int_{x_0}^{x_1} u''^2 \,\mathrm{d}x \geqslant \frac{2\varepsilon}{\delta}\left(\left(\frac{\varepsilon}{2}\right)^2 + 3(m-\varepsilon)\left(m - \frac{\varepsilon}{2}\right)\right) \geqslant \frac{\varepsilon^3}{8\delta}.$$

Hence, we obtain a contradiction with the choice of δ since Lemma 5.1 implies that

$$2\mathcal{F}(u) \geqslant s\int_{x_0}^{x_1} u''^2 \,\mathrm{d}x \geqslant \frac{s\varepsilon^3}{8\delta}.$$

Similar arguments hold in the other cases, in particular if $\lim_{x\to-\infty} u'(x) \neq 0$. □

We now turn to the proof of Proposition 5.3.

PROOF. Proof of Proposition 5.3 We divide the proof in two parts. In the first part we prove the a priori bound (property (i)) and in the second one we prove the localization of at least one minimizing sequence (property (ii)).

Let $(u_n)_n \subset \mathcal{H}$ be a minimizing sequence of $\mathcal{F}$. As $\mathcal{F}(u_n)$ is a converging sequence, $\mathcal{F}(u_n)$ is uniformly bounded. Notice that we can assume without loss of generality that $\mathcal{F}(u_n) \leqslant C \leqslant \inf_{\mathcal{H}} \mathcal{F} + 1$.

Part 1. There exists $L > 0$ such that for all $n \in \mathbb{N}$, $\|u_n\|_{C^1} \leqslant L$.

Let s be given by Lemma 5.1. According to the assumptions on f there exist $K > 0$ and $b > 0$ such that

$$\frac{3K^2 s}{8b^3} > C \quad \text{and} \quad s\, f(u) > \frac{C}{b} \quad \text{for all } |u| \geqslant \frac{K}{2}.$$

We claim that $\|u_n\|_\infty \leqslant K$. Otherwise, either the set $\{x\colon\ |u_n(x)| \geqslant K/2\}$ has measure greater than b and

$$\mathcal{F}(u_n) \geqslant s \int_{-\infty}^{+\infty} f(u_n)\, \mathrm{d}x > s\, b \frac{C}{b\, s} = C,$$

a contradiction, or we can pick up an interval (c, d) such that $d - c < b$, $|u_n(c)| = |u_n|_\infty$, $|u_n(d)| = \frac{K}{2}$, $|u_n(x)| \geqslant \frac{K}{2}$, for all $x \in (c, d)$. It then follows using Lemma 5.4 that

$$\begin{aligned}
\mathcal{F}(u_n) &\geqslant s \int_c^d \frac{u_n''^2}{2}\, \mathrm{d}x \\
&\geqslant \frac{2s}{d-c}\left(u_n'(d)^2 + 3\frac{u_n(d) - u_n(c)}{d-c}\left(\frac{u_n(d) - u_n(c)}{d-c} - u_n'(d)\right)\right) \\
&\geqslant \frac{3s}{2(d-c)}\left(\frac{u_n(d) - u_n(c)}{d-c}\right)^2 \\
&\geqslant \frac{3K^2 s}{8b^3} > C,
\end{aligned}$$

leading again to a contradiction. Hence the bound on $\|u_n\|_\infty$ is established.

Next, choosing M such that

$$M > 4K \quad \text{and} \quad M^2 > \frac{8C}{s},$$

we show that u_n' cannot attain the value M. Assume by contradiction that $u_n'(x_0) = M$. Then there exists $x_1 \in (x_0, x_0 + 1)$ such that $u_n'(x_1) = \frac{M}{2}$. Hence, denoting again $m = \frac{u_n(x_1) - u_n(x_0)}{x_1 - x_0}$, it turns out that

$$\mathcal{F}(u_n) \geqslant s \int_{x_0}^{x_1} \frac{u_n''^2}{2}\, \mathrm{d}x$$

$$\geqslant \frac{2s}{x_1 - x_0}\left(\left(\frac{M}{2}\right)^2 + 3(m-M)\left(m - \frac{M}{2}\right)\right)$$
$$\geqslant \frac{M^2 s}{8} > C,$$

which is impossible. We show in a similar way that u_n' cannot attain the value $-M$. We thus deduce that the conclusion of Part 1 holds with $L = \max(K, M)$.

Part 2. There exist $T > 0$ and a minimizing sequence $(v_n)_n \subset \mathcal{H}$ such that for all $n \in \mathbb{N}$,

$$\left|v_n(x) + 1\right| \leqslant a \quad \text{for all } x \leqslant -T$$

and

$$\left|v_n(x) - 1\right| \leqslant a \quad \text{for all } x \geqslant T.$$

Let $\varepsilon > 0$ be given. For each $n \in \mathbb{N}$, we define

$$x_1 := \sup\left\{x \in \mathbb{R} \text{ such that } \left|u_n(x) + 1\right| \leqslant \varepsilon \text{ and } \left|u_n'(x)\right| \leqslant \varepsilon\right\},$$

and

$$x_2 := \inf\left\{x \in \mathbb{R} \text{ such that } \left|u_n(x) - 1\right| \leqslant \varepsilon \text{ and } \left|u_n'(x)\right| \leqslant \varepsilon\right\}.$$

Observe that as $u_n \in \mathcal{H}$ and $\mathcal{F}(u_n) < \infty$, x_1 and x_2 are real numbers. Basically, this part of the proof consists in showing that the length $x_2 - x_1$ can be controlled uniformly in $n \in \mathbb{N}$. Then choosing $\varepsilon > 0$ sufficiently small, pieces of orbits close to ± 1 on $]-\infty, x_1[$ and $]x_2, +\infty[$ can be glued to $u_{n|[x_1,x_2]}$ without increasing the action above $\mathcal{F}(u_n)$. This rather simple argument all the same requires some technical adjustments. We first focus on the estimate of the length $x_2 - x_1$.

Step 1. For each $0 < \varepsilon < 1$, there exists $T_\varepsilon > 0$ such that for all $n \in \mathbb{N}$, $x_2 - x_1 \leqslant 2T_\varepsilon$.

Let us define $N_\varepsilon^\pm :=]\pm 1 - \varepsilon, \pm 1 + \varepsilon[$, $N_\varepsilon := N_\varepsilon^- \cup N_\varepsilon^+$ and consider the set

$$Z := \left\{x \in [x_1, x_2] \,\middle|\, u_n(x) \in N_\varepsilon\right\}.$$

Observe that Z is a union of intervals I_i on which $|u_n'| \geqslant \varepsilon$. In the sequel, we assume that these intervals I_i are of maximal length. As $|u_n'(x)| \geqslant \varepsilon$ on any interval I_i, we infer that

$$|I_i|\varepsilon \leqslant \left|\int_{I_i} u_n'(x)\,\mathrm{d}x\right| \leqslant 2\varepsilon$$

so that $|I_i| \leqslant 2$. Further except maybe for the last one, each interval I_i is followed by an interval $J_i = [c_i, d_i]$ that we also suppose to be of maximal length and which is so that one of the following conditions holds for all $x \in [c_i, d_i]$:

$$\begin{array}{llll} \text{(a)} & u_n(x) \geqslant 1+\varepsilon, & u_n'(c_i) \geqslant \varepsilon, & u_n'(d_i) \leqslant -\varepsilon, \\ \text{(b)} & -1+\varepsilon \leqslant u_n(x) \leqslant 1-\varepsilon, & \left|u_n'(c_i)\right| \geqslant \varepsilon, & \left|u_n'(d_i)\right| \geqslant \varepsilon, \\ \text{(c)} & u_n(x) \leqslant -1-\varepsilon, & u_n'(c_i) \leqslant -\varepsilon, & u_n'(d_i) \geqslant \varepsilon. \end{array}$$

Consider an interval $J_i = [c_i, d_i]$ such that (a) or (c) hold. We then obtain the estimate

$$2\varepsilon \leqslant \left|u_n'(d_i) - u_n'(c_i)\right| = \left|\int_{c_i}^{d_i} u_n''(x)\,\mathrm{d}x\right| \leqslant \|u_n''\|_{L^2(c_i,d_i)}(d_i - c_i)^{1/2}$$

and we thus infer that

$$\int_{c_i}^{d_i} \left(\frac{1}{2}\left(u_n''\right)^2 + f(u_n)\right)\mathrm{d}x \geqslant \frac{2\varepsilon^2}{d_i - c_i} + r_\varepsilon(d_i - c_i) \geqslant 2\varepsilon\sqrt{2r_\varepsilon}, \tag{5.8}$$

where $r_\varepsilon := \inf\{f(u) \mid u \notin N_\varepsilon\}$. Notice that for an interval J_i of type (b) with $u_n'(c_i)u_n'(d_i) < 0$, the same inequality holds. At last, assume that J_i is of type (b) and such that $u_n'(c_i)u_n'(d_i) > 0$. Then we obtain

$$2 - 2\varepsilon = \left|\int_{c_i}^{d_i} u_n'(x)\,\mathrm{d}x\right| \leqslant L(d_i - c_i)$$

and

$$\int_{c_i}^{d_i} \left(\frac{1}{2}\left(u_n''\right)^2 + f(u_n)\right)\mathrm{d}x \geqslant r_\varepsilon(d_i - c_i) \geqslant \frac{r_\varepsilon(2-2\varepsilon)}{L}, \tag{5.9}$$

where L is the uniform bound on $\|u_n'\|_\infty$ obtained in Part 1. Let us denote by k the number of intervals J_i. Taking the estimates (5.8) and (5.9) into account, we infer from Lemma 5.1 that

$$\begin{aligned} C \geqslant \mathcal{F}(u_n) &\geqslant s\sum_{i=1}^{k}\int_{c_i}^{d_i}\left(\frac{1}{2}\left(u_n''\right)^2 + f(u_n)\right)\mathrm{d}x \\ &\geqslant sk\min\left(2\varepsilon\sqrt{2r_\varepsilon}, \frac{r_\varepsilon(2-2\varepsilon)}{L}\right) \end{aligned} \tag{5.10}$$

so that k is uniformly bounded with respect to $n \in \mathbb{N}$.

We are now able to conclude our first step. Indeed, setting $\tilde{Z} = [x_1, x_2] \setminus Z$, we have

$$C \geqslant \mathcal{F}(u_n) \geqslant s\int_{\tilde{Z}} f\left(u_n(x)\right)\mathrm{d}x \geqslant sr_\varepsilon\left|\tilde{Z}\right|$$

and since Z is the union of at most $k+1$ intervals of length smaller than 2, we finally deduce that

$$x_2 - x_1 = |Z| + \bigl|\tilde{Z}\bigr| \leqslant 2(k+1) + \frac{C}{s\, r_\varepsilon} =: 2T_\varepsilon.$$

Step 2. Modification of u_n in $]-\infty, x_1]$ and $[x_2, +\infty[$.

We consider the modification in $]-\infty, x_1]$. Define

$$\mathcal{F}_{]-\infty,x_1]}(u) := \int_{-\infty}^{x_1} \Bigl(\frac{1}{2}\bigl(u''^2 + g(u)u'^2\bigr) + f(u)\Bigr)\, \mathrm{d}x$$

having as domain

$$\mathcal{H}^n_{]-\infty,x_1]} := \bigl\{u \in \mathcal{H} \mid u = u_n \text{ on } [x_1, +\infty[\bigr\}.$$

Using integration by parts and arguing as in Lemma 5.1, we see that for any function $u \in \mathcal{H}^n_{]-\infty,x_1]}$

$$\mathcal{F}_{]-\infty,x_1]}(u) \geqslant s \int_{-\infty}^{x_1} \Bigl(\frac{u''^2}{2} + f(u)\Bigr)\, \mathrm{d}x + \frac{1}{2}\tilde{G}\bigl(u(x_1)\bigr)u'(x_1). \tag{5.11}$$

We also consider the set

$$\mathcal{D}^n_{]-\infty,x_1]} := \bigl\{u \in \mathcal{H}^n_{]-\infty,x_1]} \bigm| \text{ for all } x \leqslant x_1,\ u(x) \in [-1-a, -1+a]\bigr\}.$$

Let us fix again the notation $N_a^- :=]-1-a, -1+a[$. We then define

$$\begin{aligned}
&\gamma := \sup\bigl\{g(u) \mid u \in N_a^-\bigr\},\\
&\eta := \inf\bigl\{f(u) \mid u \in N_a^- \setminus N_{a/2}^-\bigr\} > 0,\\
&\delta := \sup\bigl\{\bigl|\tilde{G}(u)\bigr| \mid u \in N_a^-\bigr\} \geqslant 0.
\end{aligned}$$

We first derive a lower estimate on the action of any function $u \in \mathcal{H}^n_{]-\infty,x_1]}$ whose graph does not stay in the strip $]-\infty, x_1] \times N_a^-$.

CLAIM 1. *If* $u \in \mathcal{H}^n_{]-\infty,x_1]} \setminus \mathcal{D}^n_{]-\infty,x_1]}$ *and* $\|u'\|_\infty \leqslant L$ *then*

$$\mathcal{F}_{]-\infty,x_1]}(u) \geqslant \frac{s\eta a}{2L} - \delta\varepsilon. \tag{5.12}$$

If there exists $x \leqslant x_1$ such that $u(x) \notin N_a^-$, either there exist $s_1 \leqslant s_2 \leqslant x_1$ so that

$$u(s_1) = -1 + \frac{a}{2}, \quad u(s_2) = -1 + a$$

and for all $x \in [s_1, s_2]$,

$$u(x) \in \left[-1 + \frac{a}{2}, -1 + a\right]$$

or there exist $s_3 \leqslant s_4 \leqslant x_1$ so that

$$u(s_3) = -1 - a, \qquad u(s_4) = -1 - \frac{a}{2}$$

and for all $x \in [s_3, s_4]$,

$$u(x) \in \left[-1 - a, -1 - \frac{a}{2}\right].$$

Let us for instance consider the first possibility, the second being similar. We then have

$$L(s_2 - s_1) \geqslant \int_{s_1}^{s_2} u'(x)\,\mathrm{d}x = u(s_2) - u(s_1) = \frac{a}{2}$$

and

$$\int_{-\infty}^{x_1} \left(\frac{u''^2}{2} + f(u)\right)\mathrm{d}x \geqslant \int_{s_1}^{s_2} f(u)\,\mathrm{d}x \geqslant \frac{\eta a}{2L}.$$

On the other hand, we have

$$\left|\tilde{G}\big(u(x_1)\big)u'(x_1)\right| \leqslant \delta\varepsilon,$$

so that Claim 1 now follows from (5.11).

CLAIM 2. *There exists* $R > 0$ *so that for all* $\varepsilon > 0$,

$$\inf_{\mathcal{D}^n_{]-\infty,x_1]}} \mathcal{F}_{]-\infty,x_1]} \leqslant R\varepsilon^2.$$

For a function $u \in \mathcal{D}^n_{]-\infty,x_1]}$, we have by virtue of (C2)

$$\mathcal{F}_{]-\infty,x_1]}(u) \leqslant \int_{-\infty}^{x_1} \left(\frac{1}{2}\big(u''^2 + \gamma u'^2\big) + \alpha(u+1)^2\right)\mathrm{d}x.$$

Let us define the functional

$$\mathcal{J}_{]-\infty,x_1]}(u) := \int_{-\infty}^{x_1} \left(\frac{1}{2}\big(u''^2 + \gamma u'^2\big) + \alpha(u+1)^2\right)\mathrm{d}x$$

on $\mathcal{H}^n_{]-\infty,x_1]}$. Let P be the third degree polynomial satisfying $P(x_1-1)=-1$, $P'(x_1-1)=0$, $P(x_1)=u_n(x_1)$ and $P'(x_1)=u_n'(x_1)$. The function $v:]-\infty,x_1]\to\mathbb{R}$ defined by

$$v(x):=\begin{cases}0 & \text{if } x<x_1-1\\ P(x) & \text{if } x_1-1\leqslant x\leqslant x_1.\end{cases}$$

belongs to $\mathcal{H}^n_{]-\infty,x_1]}$ and in fact to $\mathcal{D}^n_{]-\infty,x_1]}$ if ε is taken sufficiently small. A straightforward computation then shows that there is a constant $C(\gamma,\alpha)$ such that

$$\mathcal{J}_{]-\infty,x_1]}(v)\leqslant C(\gamma,\alpha)\big(\big(u_n(x_1)+1\big)^2+u_n'(x_1)^2\big)\leqslant 2C(\gamma,\alpha)\varepsilon^2$$

so that we obtain the estimate

$$\inf_{\mathcal{D}^n_{]-\infty,x_1]}}\mathcal{F}_{]-\infty,x_1]}\leqslant\inf_{\mathcal{D}^n_{]-\infty,x_1]}}\mathcal{J}_{]-\infty,x_1]}\leqslant 2C(\gamma,\alpha)\varepsilon^2.$$

Conclusion of Step 2. Let us choose $\varepsilon>0$ sufficiently small in order to have

$$\mathcal{F}_{]-\infty,x_1]}(u)\geqslant\frac{s\eta a}{4L}$$

for $u\in\mathcal{H}^n_{]-\infty,x_1]}\setminus\mathcal{D}^n_{]-\infty,x_1]}$ satisfying $\|u'\|_\infty\leqslant L$ and

$$\inf_{\mathcal{D}^n_{]-\infty,x_1]}}\mathcal{F}_{]-\infty,x_1]}<\frac{s\eta a}{4L}.$$

If $u_n\notin\mathcal{D}^n_{]-\infty,x_1]}$, we infer from the above estimates that we can replace u_n by $v_n\in\mathcal{D}^n_{]-\infty,x_1]}$ such that $\mathcal{F}(v_n)\leqslant\mathcal{F}(u_n)$.

If $|u_n(x)-1|\nleqslant a$ for $x\geqslant x_2$ we proceed in the same way to modify u_n for $x\geqslant x_2$.

We are now in position to complete the proof of Part 2. Indeed, we deduce from Step 1 and Step 2 that there exist $T>0$ and a minimizing sequence $(v_n)_n$ such that for all $n\in\mathbb{N}$, there exist $x_1<x_2$ satisfying $x_2-x_1\leqslant 2T$ and

$$\big|v_n(x)+1\big|\leqslant a\quad\text{for all } x\leqslant x_1,$$

$$\big|v_n(x)-1\big|\leqslant a\quad\text{for all } x\geqslant x_2.$$

Translating v_n if necessary, we can assume $[x_1,x_2]\subset[-T,T]$ so that the conclusion of the second part follows. Observe that since $\mathcal{F}(v_n)\leqslant\mathcal{F}(u_n)$, the sequence $(v_n)_n$ satisfies the a priori bound derived in the first part. This ends the proof. □

5.2. *Functionals of Swift–Hohenberg type*

When β is negative, the model equation

$$u''''-\beta u''+u^3-u=0$$

is related to the *Swift–Hohenberg* equation

$$\frac{\partial u}{\partial t} - \kappa u + \left(1 + \frac{\partial^2}{\partial x^2}\right)^2 u + u^3 = 0, \tag{5.13}$$

where $\kappa \in \mathbb{R}$. This equation was proposed by Swift and Hohenberg [84] as a model for studies of Rayleigh–Bénard convection. When $\kappa > 1$, after rescaling, (5.13) can be written as

$$\frac{\partial u}{\partial t} + (\kappa - 1)^{3/2}\left(\frac{\partial^4 u}{\partial x^4} - \beta \frac{\partial^2 u}{\partial x^2} + u^3 - u\right) = 0$$

with $\beta = -2/\sqrt{\kappa - 1}$. The compatibility condition (C1) between f and g allows g to take negative values but it then implies that g takes positive values as well. Therefore, the stationary Swift–Hohenberg equation is not covered by the result of the preceding section.

When stronger assumptions are imposed on the potential, we can deal with negative functions g. Namely we assume that $f, g \in C^1(\mathbb{R})$ are even functions such that $f(1) = 0$ and

(C5) for some $k > 0$, $\beta < \sqrt{8k}$ and all $u \geqslant 0$,

$$f(u) \geqslant k(u-1)^2 \quad \text{and} \quad g(u) \geqslant -\beta.$$

We look then at the minimizers of the functional $\mathcal{F}$ defined by (5.2) in the space

$$\mathcal{E} = \left\{u \mid u(0) = 0,\ u + 1 \in H^2(\mathbb{R}^-),\ u - 1 \in H^2(\mathbb{R}^+)\right\}.$$

Our first observation is that under the assumption (C5), for small $\beta > 0$,

$$\inf_{u \in \mathcal{E}} \mathcal{F}(u) > -\infty.$$

LEMMA 5.6. *Let f and $g \in C(\mathbb{R})$ be even functions such that* (C5) *holds. Then there exists $\beta_1 > 0$ such that for $\beta \leqslant \beta_1$, we have*

$$\inf_{u \in \mathcal{E}} \mathcal{F}(u) \geqslant 0.$$

PROOF. Let us first recall the following interpolation inequality, see for example [1]. For all $\ell > 0$, there exists $C > 0$ such that for any interval I with $|I| \geqslant \ell$ and all $u \in H^2(I)$,

$$\|u'\|^2_{L^2(I)} \leqslant C\left(\|u\|^2_{L^2(I)} + \|u''\|^2_{L^2(I)}\right). \tag{5.14}$$

Let u be any function in $\mathcal{E}$ and consider an interval $[a, b]$ where u is nonnegative and $u(a) = u(b) = 0$. Suppose that $b - a \geqslant 1$. Then using the inequality (5.14) applied to $u - 1$, we obtain

$$\begin{aligned}\int_a^b \left(\frac{1}{2}\left(u''^2 + g(u)u'^2\right) + f(u)\right) \mathrm{d}x &\geqslant \int_a^b \left(\frac{1}{2}\left(u''^2 - \beta u'^2\right) + k(u-1)^2\right) \mathrm{d}x \\ &\geqslant \frac{1-\beta C}{2} \left\|u''\right\|^2_{L^2(a,b)} \\ &\quad + \left(k - \frac{\beta C}{2}\right) \|u-1\|^2_{L^2(a,b)}. \end{aligned} \tag{5.15}$$

If $b - a < 1$, we compute

$$\left\|u'\right\|_{L^2(a,b)} \leqslant \frac{b-a}{\sqrt{2}} \left\|u''\right\|_{L^2(a,b)}$$

and

$$\begin{aligned}\int_a^b \left(\frac{1}{2}\left(u''^2 - g(u)u'^2\right) + f(u)\right) \mathrm{d}x &\geqslant \int_a^b \left(\frac{1}{2}\left(u''^2 - \beta u'^2\right) + f(u)\right) \mathrm{d}x \\ &\geqslant \frac{1}{2}\left(1 - \frac{\beta}{2}\right) \left\|u''\right\|^2_{L^2(a,b)}. \end{aligned}$$

In both cases, we obtain

$$\int_a^b \left(\frac{1}{2}\left(u''^2 + g(u)u'^2\right) + f(u)\right) \mathrm{d}x \geqslant 0$$

if $\beta \leqslant \min(2, 1/C, 2k/C)$. A similar argument holds on intervals $[a, b]$ where u is non positive. At last, if u is nonnegative on the interval $[T, +\infty[$, we deduce as in (5.15) that

$$\int_a^{+\infty} \left(\frac{1}{2}\left(u''^2 + g(u)u'^2\right) + f(u)\right) \mathrm{d}x \geqslant 0.$$

The conclusion follows. □

Next, assuming that the functional $\mathcal{F}$ is bounded from below, we prove the existence of a minimizer. We deduce from the previous lemma that the result holds at least when $g \geqslant -\beta$ with $\beta > 0$ small.

THEOREM 5.7. *Let $f \in C^1(\mathbb{R})$ and $g \in C^1(\mathbb{R})$ be even functions such that $f(1) = 0$ and* (C5) *holds. Assume further that*

$$\inf_{\mathcal{E}} \mathcal{F} > -\infty.$$

Then $\mathcal{F}$ has a minimizer which is a heteroclinic solution of Eq. (5.3) *having exactly one zero. Moreover, any minimizer is odd.*

PROOF. *Step* 1. We first prove the existence of an odd minimizing sequence $(u_n)_n$ such that $u_n(x) > 0$ for all $x > 0$. Let $(v_n)_n \subset \mathcal{E}$ be a minimizing sequence. Observe that if v_n is not odd, the appropriate symmetrization of v_n restricted to $\mathbb{R}^+$ or $\mathbb{R}^-$ decreases the action. Assume now that v_n has a positive zero and define

$$x_n := \sup\bigl\{x > 0 \bigm| v_n(x) = 0\bigr\}.$$

We claim that

$$\mathcal{F}_{[-x_n,x_n]}(v_n) := \int_{-x_n}^{x_n} \left(\frac{1}{2}\bigl(v_n''^2 + g(v_n)v_n'^{\,2}\bigr) + f(v_n)\right) \mathrm{d}x \geqslant 0.$$

Indeed, suppose that $\mathcal{F}_{[-x_n,x_n]}(v_n) = -C < 0$ and take $j \in \mathbb{N}$ so that $\mathcal{F}(v_n) - 2jC < \inf_{\mathcal{E}} \mathcal{F}$. Then defining the odd function $u_n^* \in \mathcal{E}$ by

$$u_n^*(x) := \begin{cases} v_n(x - 2ix_n) & \text{if } x \in \bigl[2ix_n, (2i+1)x_n\bigl[, \ i = 0, \dots, j, \\ -v_n(2ix_n - x) & \text{if } x \in \bigl[(2i-1)x_n, 2ix_n\bigl[, \ i = 1, \dots, j, \\ v_n\bigl(x - 2(j+1)x_n\bigr) & \text{if } x \in \bigl[(2j+1)x_n, +\infty\bigl[, \end{cases}$$

we obtain a contradiction because

$$\mathcal{F}\bigl(u_n^*\bigr) = \mathcal{F}(v_n) + 2j\mathcal{F}_{[-x_n,x_n]}(v_n) = \mathcal{F}(v_n) - 2jC < \inf_{\mathcal{E}} \mathcal{F}.$$

Now, let $u_n \in \mathcal{E}$ be the odd function defined by $u_n(x) = v_n(x + x_n)$ for $x \geqslant 0$. This function u_n vanishes only at 0 and since $\mathcal{F}_{[-x_n,x_n]}(v_n) \geqslant 0$, the sequence $(u_n)_n$ is also a minimizing sequence.

Step 2. As there exists an odd minimizing sequence, it is sufficient to minimize the restricted functional

$$\mathcal{F}^+(u) := \int_0^{+\infty} \left(\frac{1}{2}\bigl(u''^2 + g(u)u'^2\bigr) + f(u)\right) \mathrm{d}x$$

in the space of functions

$$\mathcal{E}^+ = \bigl\{u : \mathbb{R}^+ \to \mathbb{R} \bigm| u(0) = 0,\ u - 1 \in H^2\bigl(\mathbb{R}^+\bigr)\bigr\}.$$

We first claim that $u_n - 1$ is uniformly bounded in $H^2(\mathbb{R}^+)$. To prove this, we compute for $u \in \mathcal{E}^+$,

$$\begin{aligned} &\int_0^{+\infty} \left(\frac{1}{2}\bigl(u''^2 - \beta u'^2\bigr) + k(u-1)^2\right) \mathrm{d}x \\ &\quad = \varepsilon\|u - 1\|_{H^2}^2 + \frac{1 - 2\varepsilon}{2} \int_0^{+\infty} \left(u''^2 - \beta_\varepsilon u'^2 + \frac{1}{4}\beta_\varepsilon^2 (u-1)^2\right) \mathrm{d}x \\ &\qquad + \left(k - \varepsilon - \frac{(\beta + 2\varepsilon)^2}{8(1 - 2\varepsilon)}\right) \int_0^{+\infty} (u-1)^2 \,\mathrm{d}x, \end{aligned}$$

where $\beta_\varepsilon := \frac{\beta+2\varepsilon}{1-2\varepsilon}$. Notice that we may choose ε small enough in order to have $k-\varepsilon-\frac{(\beta+2\varepsilon)^2}{8(1-2\varepsilon)} \geqslant 0$. For the second term of the right-hand side, we have

$$\begin{aligned}\int_0^{+\infty}\left(u''^2-\beta_\varepsilon u'^2+\frac{\beta_\varepsilon^2}{4}(u-1)^2\right)\mathrm{d}x\\ =\int_0^{+\infty}\left(u''+\frac{\beta_\varepsilon}{2}(u-1)\right)^2\mathrm{d}x-\beta_\varepsilon u'(0)\geqslant -\beta_\varepsilon u'(0).\end{aligned}$$

As u_n is positive, we infer that

$$\begin{aligned}\mathcal{F}^+(u_n)&\geqslant\int_0^{+\infty}\left(\frac{1}{2}\big(u_n''^2-\beta u_n'^2\big)+k(u_n-1)^2\right)\mathrm{d}x\\ &\geqslant\varepsilon\|u_n-1\|_{H^2}^2-\beta_\varepsilon u_n'(0).\end{aligned}$$

We now deduce from the continuous injection of $H^2(0,\infty)$ into $\mathcal{C}^1([0,\infty[)$ that for some $C>0$

$$\mathcal{F}^+(u_n)\geqslant\varepsilon\|u_n-1\|_{H^2(0,\infty)}^2-C\|u_n-1\|_{H^2(0,\infty)}.$$

Hence, the claim follows from the uniform bound on $\mathcal{F}(u_n)$.

We now infer that at least for a subsequence (that we still denote by u_n)

$$u_n-1\overset{H^2(\mathbb{R}^+)}{\rightharpoonup}u-1\quad\text{and}\quad u_n\overset{C^1_{\mathrm{loc}}(\mathbb{R}^+)}{\longrightarrow}u$$

for some function $u\in\mathcal{E}^+$. In order to see that u is a minimizer, we write

$$\begin{aligned}\mathcal{F}^+(u_n)&=\frac{1}{2}\int_0^{+\infty}\left(u_n''^2-\beta u_n'^2+\frac{\beta^2}{4}(u_n-1)^2\right)\mathrm{d}x\\ &\quad+\frac{1}{2}\int_0^{+\infty}\big((g(u_n)+\beta)u_n'^2\big)\,\mathrm{d}x+\int_0^{+\infty}\left(f(u_n)-\frac{\beta^2}{8}(u_n-1)^2\right)\mathrm{d}x\\ &=\frac{1}{2}\int_0^{+\infty}\left(u_n''+\frac{\beta}{2}(u_n-1)\right)^2\mathrm{d}x-\frac{\beta}{2}u_n'(0)\\ &\quad+\frac{1}{2}\int_0^{+\infty}\big((g(u_n)+\beta)u_n'^2\big)\,\mathrm{d}x+\int_0^{+\infty}\left(f(u_n)-\frac{\beta^2}{8}(u_n-1)^2\right)\mathrm{d}x.\end{aligned}$$

Observe then that in the last equality, the first integral is convex and that Fatou's Lemma is applicable to the last two so that

$$\mathcal{F}^+(u)\leqslant\lim_{n\to+\infty}\mathcal{F}^+(u_n)=\inf_{\mathcal{E}^+}\mathcal{F}^+.$$

Now, as $u \in \mathcal{E}^+$, we conclude that $\mathcal{F}^+(u) = \inf_{\mathcal{E}^+} \mathcal{F}^+$ and still denoting by u its odd extension on $\mathbb{R}$, we have $\mathcal{F}(u) = \inf_{\mathcal{E}} \mathcal{F}$.

The proof that any minimizer is odd follows the lines of the third step of the proof of Theorem 4.5. □

In the following theorem, we observe that when ±1 are saddle-foci, the minimum of $\mathcal{F}$ is non-negative.

THEOREM 5.8. *Let f and $g \in C^2(\mathbb{R})$ be even functions such that $f(1) = 0$, $g(1)^2 < 4f''(1)$ and assume that* (C5) *holds. Then if u is a minimizer in $\mathcal{E}$ of $\mathcal{F}$, $\mathcal{F}(u) \geqslant 0$.*

In order to prove Theorem 5.8, we first consider the following lemma which states that if $+1$ is a saddle-focus stationary point, then the solutions of (5.3) that converge to $+1$ in the phase-space, do oscillate around the equilibrium in their tails. To simplify the notation, we assume the equilibria has been translated to 0.

LEMMA 5.9. *Let f and $g \in C^2(\mathbb{R})$ and $f(0) = 0$. Let 0 be a saddle-focus equilibria for the linearization of Eq.* (5.3), *i.e. $g(0)^2 < 4f''(0)$. Then, there exists $\Delta > 0$ such that if $\hat{u}$ is a nontrivial solution of* (5.3) *that satisfies*

$$\lim_{x \to +\infty} \big(\hat{u}(x), \hat{u}'(x), \hat{u}''(x), \hat{u}'''(x)\big) = (0, 0, 0, 0), \tag{5.16}$$

$\hat{u}$ changes sign in any interval $[x_0, x_0 + \Delta]$ for sufficiently large x_0.

PROOF. Let $\hat{u}$ be a solution of (5.3) that satisfies (5.16). Consider the linearization of (5.3)

$$z'''' - g(0)z'' + f''(0)z = 0. \tag{5.17}$$

Notice that the characteristic values of this linear equation read $\pm\rho \pm i\omega$. We then choose $\Delta = 2\pi/\omega$. Let $x_0 \in \mathbb{R}$ and $z_0 \in \mathbb{R}^4$. By the choice of Δ, the solution z of (5.17) with initial condition

$$\big(z(x_0), z'(x_0), z''(x_0), z'''(x_0)\big) = z_0$$

satisfies

$$\max_{[x_0, x_0+\Delta]} z, \quad \max_{[x_0, x_0+\Delta]} (-z) \geqslant c|z_0|$$

and

$$\|z\|_{C^2([x_0, x_0+\Delta])} \leqslant M|z_0|$$

for some $c > 0$ and $M > 0$ depending only on Δ, $g(0)$ and $f''(0)$. On the other hand, we can also find $N > 0$ so that the solutions of

$$\begin{aligned}&w'''' - g(0)w'' + f''(0)w = h(x),\\&\big(w(x_0), w'(x_0), w''(x_0), w'''(x_0)\big) = 0,\end{aligned}$$

satisfy

$$\|w\|_{\mathcal{C}^2([x_0,x_0+\Delta])} \leqslant N\|h\|_{L^\infty(x_0,x_0+\Delta)}.$$

Next, we take $\delta > 0$ so that $c - \frac{MN\delta}{1-N\delta} > 0$.

To fix the ideas we denote by $u(x; x_0, u_0)$ the solution of (5.3) with initial conditions $x_0 \in \mathbb{R}$, $u_0 := (u(x_0), u'(x_0), u''(x_0), u'''(x_0))$. Let $\tilde{u}(x; \lambda) = u(x; x_0, \lambda\hat{u}_0)$, with $\hat{u}_0 = (\hat{u}(x_0), \hat{u}'(x_0), \hat{u}''(x_0), \hat{u}'''(x_0))$ and define

$$\begin{aligned}&p(x) = -g\big(\tilde{u}(x; \lambda)\big),\\&q(x) = -g'\big(\tilde{u}(x; \lambda)\big)\tilde{u}'(x; \lambda),\end{aligned}$$

and

$$r(x) = -g'\big(\tilde{u}(x; \lambda)\big)\tilde{u}''(x; \lambda) - \frac{1}{2}g''\big(\tilde{u}(x; \lambda)\big)\tilde{u}'^2(x; \lambda) + f''\big(\tilde{u}(x; \lambda)\big).$$

Let us fix now x_0 large enough so that $|\hat{u}_0|$ is small enough to have, for $0 \leqslant \lambda \leqslant 1$,

$$\sup_{x_0 \leqslant x \leqslant x_0+\Delta} \big|p(x) + g(0)\big|, \quad \sup_{x_0 \leqslant x \leqslant x_0+\Delta} \big|q(x)\big|, \quad \sup_{x_0 \leqslant x \leqslant x_0+\Delta} \big|r(x) - f''(0)\big| \leqslant \delta.$$

Observe also that $|\hat{u}_0| \neq 0$ as a nonzero solution cannot reach 0 in the phase-space in a finite time. We then write

$$\hat{u}(x) = \int_0^1 \frac{\mathrm{d}}{\mathrm{d}\lambda} u(x; x_0, \lambda\hat{u}_0)\,\mathrm{d}\lambda.$$

The function

$$\varphi(x; x_0, \hat{u}_0, \lambda) = \frac{\mathrm{d}}{\mathrm{d}\lambda} u(x; x_0, \lambda\hat{u}_0)$$

satisfies the Cauchy problem

$$\begin{aligned}&\varphi'''' + p(x)\varphi'' + q(x)\varphi' + r(x)\varphi = 0,\\&\big(\varphi(x_0), \varphi'(x_0), \varphi''(x_0), \varphi'''(x_0)\big) = \hat{u}_0,\end{aligned}$$

and we can write

$$\varphi = w + z.$$

Here w solves the equation

$$\begin{aligned} & w'''' - g(0)w'' + f''(0)w \\ & \quad = -\big(g(0) + p(x)\big)\varphi''(x) - q(x)\varphi'(x) + \big(f''(0) - r(x)\big)\varphi(x), \end{aligned}$$

together with the initial values

$$\big(w(x_0), w'(x_0), w''(x_0), w'''(x_0)\big) = 0$$

and z is a solution of

$$\begin{aligned} & z'''' - g(0)z'' + f''(0)z = 0, \\ & \big(z(x_0), z'(x_0), z''(x_0), z'''(x_0)\big) = \hat{u}_0. \end{aligned}$$

We next choose $\overline{x} \in [x_0, x_0 + \Delta]$ so that

$$z(\overline{x}) \geqslant c|\hat{u}_0|$$

and compute

$$\hat{u} = z + \int_0^1 w \, \mathrm{d}\lambda.$$

Notice that

$$\|w\|_{\mathcal{C}^2([x_0,x_0+\Delta])} \leqslant N\delta\|\varphi\|_{\mathcal{C}^2([x_0,x_0+\Delta])}.$$

We then obtain the estimates,

$$\|w\|_{\mathcal{C}^2([x_0,x_0+\Delta])} \leqslant \frac{N\delta}{1 - N\delta}\|z\|_{\mathcal{C}^2([x_0,x_0+\Delta])} \leqslant \frac{MN\delta}{1 - N\delta}|\hat{u}_0|.$$

At last, we have

$$\hat{u}(\overline{x}) \geqslant c|\hat{u}_0| - \|w\|_\infty \geqslant \left(c - \frac{MN\delta}{1 - N\delta}\right)|\hat{u}_0| > 0.$$

Arguing in a similar way, we find $\underline{x} \in [x_0, x_0 + \Delta]$ so that $\hat{u}(\underline{x}) < 0$. □

We now come back to the proof of Theorem 5.8.

PROOF OF THEOREM 5.8. Let $u \in \mathcal{E}$ be such that $\mathcal{F}(u) = \inf_{\mathcal{E}} \mathcal{F} = -C$ for some $C > 0$. As u is a minimizer, it satisfies Eq. (5.3) and we also have

$$\lim_{x \to +\infty} \big(u(x), u'(x), u''(x), u'''(x)\big) = (1, 0, 0, 0).$$

Observe that Theorem 5.7 implies that u is odd so that

$$\mathcal{F}(u) = 2\int_0^{+\infty}\left(\frac{1}{2}\left(u''^2 + g(u)u'^2\right) + f(u)\right)\mathrm{d}x = -C.$$

As a consequence of Lemma 5.9, u oscillates around $+1$ at $+\infty$. Hence, we can find $T > 0$ large enough so that

$$\int_0^T\left(\frac{1}{2}\left(u''^2 + g(u)u'^2\right) + f(u)\right)\mathrm{d}x \leqslant -C/4,$$

and $u'(T) = 0$. Defining the odd function $v^* \in \mathcal{E}$ as follows:

$$v^*(x) = \begin{cases} u(x) & \text{if } x \in [0, T), \\ u(2T - x) & \text{if } x \in [T, 2T), \\ -u(x - 2T) & \text{if } x \in [2T, 3T], \\ -u(4T - x) & \text{if } x \in [3T, 4T], \\ u(x - 4T) & \text{if } x \geqslant 4T, \end{cases}$$

we have

$$\begin{aligned}\mathcal{F}(v^*) = 8&\int_0^T\left(\frac{1}{2}\left(u''^2 + g(u)u'^2\right) + f(u)\right)\mathrm{d}x \\ &+ 2\int_0^{+\infty}\left(\frac{1}{2}\left(u''^2 + g(u)u'^2\right) + f(u)\right)\mathrm{d}x < -2C.\end{aligned}$$

This contradicts the definition of u. Hence, we have $\inf_{\mathcal{E}}\mathcal{F} \geqslant 0$. □

We next state an obvious corollary of Theorem 5.8.

COROLLARY 5.10. *Let f and $g \in C^2(\mathbb{R})$ be even functions such that $f(1) = 0$ and* (C5) *holds. Assume, moreover, that $g(1)^2 < 4f''(1)$. If there exists $u \in \mathcal{E}$ such that $\mathcal{F}(u) < 0$, then* $\inf_{\mathcal{E}}\mathcal{F} = -\infty$.

PROOF. Suppose by contradiction that the conclusion of the corollary is false. Then Theorem 5.7 implies the existence of a minimizer which has a negative action. This contradicts Theorem 5.8. □

Let us consider the stationary Swift–Hohenberg equation

$$u'''' + \beta u'' + u^3 - u = 0. \tag{5.18}$$

We know from Theorem 5.7 and Lemma 5.6 that the corresponding functional

$$\mathcal{F}_\beta(u) = \int_{-\infty}^{+\infty}\left(\frac{1}{2}\left(u''^2 - \beta u'^2\right) + \frac{1}{4}\left(u^2 - 1\right)^2\right)\mathrm{d}x$$

has a minimum in $\mathcal{E}$ for β lower than some small positive constant. If β becomes too large, the minimum no longer exists. Indeed, it is shown in [55] that taking the function $u(x) = A(\beta)\sin(\omega(\beta)x)$ where $A(\beta) = \sqrt{\frac{\beta^2+4}{3}}$ and $\omega(\beta) = \sqrt{\frac{\beta}{2}}$, we have

$$\int_0^{2\pi/\omega(\beta)} \left(\frac{1}{2}\left(u''^2 - \beta u'^2\right) + \frac{1}{4}\left(u^2-1\right)^2\right) \mathrm{d}x < 0 \tag{5.19}$$

if $\beta > \beta^* = \sqrt{2\sqrt{6}-4} = 0.9481\ldots$. It follows that the functional is unbounded from below whenever $\beta > \beta^*$. Therefore, there exists $0 < \beta_0 \leqslant \beta^*$ such that for $\beta > \beta_0$, the functional is unbounded from below. We give in the next theorem a characterization of β_0, which shows also that the minimum of $\mathcal{F}_\beta$ exists whenever $\beta \in (-\infty, \beta_0]$.

THEOREM 5.11. *Let β_0 be defined by*

$$\beta_0 = \sup\left\{\beta > 0 \;\middle|\; \inf_{\mathcal{E}} \mathcal{F}_\beta \geqslant 0\right\}.$$

Then $\beta_0 \in\,]0, \beta^*\,]$ and for all $\beta \leqslant \beta_0$, $\mathcal{F}_\beta$ has a minimum which is an odd heteroclinic solution of (5.18) *with exactly one zero. Moreover, for all $\beta > \beta_0$, $\mathcal{F}_\beta$ is unbounded from below.*

PROOF. For $u \geqslant 0$, we have $(u^2-1)^2/4 \geqslant (u-1)^2/4$ so that Theorem 5.7 is valid for $\beta < \sqrt{2}$. It follows from Lemma 5.6 and Theorem 5.7 that for small $\beta > 0$, there exists $u \in \mathcal{E}$ such that $\mathcal{F}_\beta(u) = \inf_{\mathcal{E}} \mathcal{F}_\beta$. Also we deduce from (5.19) that $\beta_0 \leqslant \beta^*$.

Notice now that $\inf_{\mathcal{E}} \mathcal{J}_{\beta_0} \geqslant 0$. If it were not the case, the same would hold true for β near enough β_0, which contradicts the definition of β_0. Next, as $\beta_0 \leqslant \beta^* < \sqrt{2}$, we infer from Theorem 5.7 that for any $\beta \leqslant \beta_0$, $\mathcal{F}_\beta$ has an odd minimizer having exactly one zero.

It follows also from Corollary 5.10 that if $\beta_0 < \beta < \sqrt{2}$, $\mathcal{F}_\beta$ is unbounded from below. In case $\sqrt{2} \leqslant \beta$ the conclusion follows from (5.19). □

Numerical computations [87] seems to indicate that heteroclinic solutions of (5.18) exist at least until $\beta \approx 2.32$. Theorem 5.11 shows that for $\beta > \beta_0$, these critical points are not global minima.

5.3. *Notes and further comments*

1. The solution u obtained in Theorem 5.2 can be seen as a heteroclinic solution in a weak sense as it does not satisfy in general the usual conditions at ±∞, namely

$$\lim_{x\to\pm\infty} \left(u, u', u'', u'''\right)(x) = (\pm 1, 0, 0, 0).$$

However the limits for u and u' hold and it is easily seen that u is in the manifold of zero energy which is the case for classical heteroclinics. Indeed, the conservation of the Hamiltonian

$$H\big(u, u', u'', u'''\big) = u'''u' - \frac{1}{2}u''^2 - \frac{1}{2}g(u)u'^2 + f(u),$$

implies $H(u(x)\, u'(x), u''(x), u'''(x)) = E$ for any $x \in \mathbb{R}$ and some $E \in \mathbb{R}$. Assume $E \neq 0$ and let $(x_n)_n \subset \mathbb{R}^+$ be such that $x_n \to +\infty$ and $(u''(x_n))_n \subset \mathbb{R}$ is a bounded sequence. Then we have

$$\int_0^{x_n} \left(u'''u' - \frac{1}{2}u''^2 - \frac{1}{2}g(u)u'^2 + f(u) \right) \mathrm{d}x = Ex_n.$$

Integrating by parts the first term of the left hand side, we notice that the integral is bounded contradicting the equality.

If in addition to the hypotheses of Theorem 5.2 we suppose that f satisfies for some $0 < b < 1/2$ and $\beta > 0$,

$$\frac{f(u)}{(u-1)^2} \geqslant \beta, \quad \text{for all } u \in (1-b, 1+b),$$
$$\frac{f(u)}{(u+1)^2} \geqslant \beta, \quad \text{for all } u \in (-1-b, -1+b),$$

then it is easily seen that a minimizer u of $\mathcal{F}$ in $\mathcal{H}$ satisfies $u + 1 \in L^2(\mathbb{R}^-)$ and $u - 1 \in L^2(\mathbb{R}^+)$. Now, as we also have $u'' \in L^2(\mathbb{R})$, we infer by interpolation that $u' \in L^2(\mathbb{R})$ and thus the minimizer u actually satisfies $u + 1 \in H^2(\mathbb{R}^-)$ and $u - 1 \in H^2(\mathbb{R}^+)$. Using Eq. (5.3), we conclude that $u'''' \in L^2(\mathbb{R})$ which in turn by interpolation implies $u - 1 \in H^4(\mathbb{R}^+)$ and $u + 1 \in H^4(\mathbb{R}^-)$. The limits at $\pm\infty$ for u'' and u''' follow now easily.

Notice that the above additional assumptions hold if -1 and $+1$ are nondegenerate minima of f.

2. Theorem 5.7 can be extended to a nonsymmetric functional, assuming for instance that for some $k_1, k_2 > 0$, $\beta_1, \beta_2 \in \mathbb{R}$,

$$f(u) \geqslant k_1(u-1)^2, \quad g(u) \geqslant -\beta_1 \quad \text{for } u \geqslant 0,$$

$$f(u) \geqslant k_2(u+1)^2, \quad g(u) \geqslant -\beta_2 \quad \text{for } u < 0$$

and $\beta_i < \sqrt{8k_i}$ for $i = 1, 2$. However, the proof is much more involved and requires the cutting method we introduce in the following section.

3. A sharp estimate of the critical parameter β_0 introduced in Theorem 5.11 is still missing. A very rough estimate can be obtained via Lemma 5.6 and an estimate of the best constant for the interpolation inequality used therein. However, this estimate is far from the numerical observation of van den Berg who claims $\beta_0 \approx 0.92$, see Conjecture 7 in [87].

4. Let us define $\mathcal{E}_0^+$ as the cone of positive functions in $\mathcal{E}^+$, i.e.

$$\mathcal{E}_0^+ := \{u \in \mathcal{E}^+ \mid u(x) > 0 \text{ for } x > 0\}$$

and $\mathcal{F}_\beta^+ : \mathcal{E}^+ \to \mathbb{R}$ the restricted functional

$$\mathcal{F}_\beta^+(u) = \int_0^{+\infty} \left(\frac{1}{2}\left(u''^2 - \beta u'^2\right) + \frac{1}{4}\left(u^2 - 1\right)^2\right) \mathrm{d}x.$$

It follows from Theorem 5.11 that $\mathcal{F}_\beta^+$ has a minimizer in $\mathcal{E}^+$ for every $\beta \leqslant \beta_0$. Moreover this minimizer belongs to the interior of $\mathcal{E}_0^+$. Indeed, as mentioned in Section 4.1, the Hamiltonian

$$H\left(u, u', u'', u'''\right) = u'''u' - \frac{1}{2}u''^2 - \frac{\beta}{2}u'^2 + \frac{(u^2 - 1)^2}{4}$$

is constant along solutions. As for any minimizer φ, $H(\varphi, \varphi', \varphi'', \varphi''') = 0$ and $\varphi''(0) = 0$, we deduce from the conservation of the Hamiltonian that $\varphi'(0) > 0$. On the other hand, we deduce from Step 2 of the proof of Theorem 5.7 that

$$\inf_{\mathcal{E}_0^+} \mathcal{F}_\beta^+ > -\infty$$

for every $\beta < \sqrt{2}$. Hence it is natural to ask if $\mathcal{F}_\beta^+$ has a local minimizer in the interior of $\mathcal{E}_0^+$ for $\beta_0 \leqslant \beta < \sqrt{2}$. To our knowledge, this question remains open. However, we can observe that an argument of continuity implies that the answer is positive at least for β close to β_0. Indeed, it is easily seen that $\mathcal{F}_\beta^+$ has a local minimizer in $\mathcal{E}_0^+$ for every $\beta < \sqrt{2}$. For $\beta \leqslant \beta_0$, we can prove that the minimizers cannot be on the boundary of $\mathcal{E}_0^+$ so that

$$\mathcal{F}_{\beta_0}^+(\varphi_{\beta_0}) < \inf_{\partial\mathcal{E}_0^+} \mathcal{F}_{\beta_0}^+, \tag{5.20}$$

where φ_{β_0} is a minimizer of $\mathcal{F}_{\beta_0}^+$. On the other hand, we have for $\beta_1 < \sqrt{2}$ and $\beta \in [\beta_0, \beta_1]$,

$$\mathcal{F}_\beta^+(u) = \mathcal{F}_{\beta_1}^+(u) + \frac{\beta_1 - \beta}{2} \int_0^{+\infty} u'^2 \, \mathrm{d}x \geqslant -C + \frac{\beta_1 - \beta}{2} \int_0^{+\infty} u'^2 \, \mathrm{d}x.$$

We now infer from this last estimate that any function $u \in \mathcal{E}_0^+$ satisfying

$$\mathcal{F}_\beta^+(u) = \inf_{\partial\mathcal{E}_0^+} \mathcal{F}_\beta^+$$

is a priori bounded in $\mathcal{E}^+$ for β in any compact subinterval of $[\beta_0, \beta_1[$. It follows that the inequality (5.20) holds true for β in a right neighborhood of β_0, i.e.

$$\mathcal{F}_\beta^+(\varphi_{\beta_0}) < \inf_{\partial\mathcal{E}_0^+} \mathcal{F}_\beta^+.$$

Since φ_{β_0} is in the interior of $\mathcal{E}_0^+$, this means that the infimum of $\mathcal{F}_\beta^+$ in $\mathcal{E}_0^+$ cannot be achieved on the boundary.

6. A Ginzburg–Landau model for ternary mixtures: Connections between nonconsecutive equilibria

A good example of phase transition phenomena is provided by the mixing–demixing transitions of a fluid. It is well known that oil and water do not mix so that a binary fluid composed of oil and water has two separated homogeneous phases usually called oil-rich and water-rich phases. Assuming that the essence of the transitions can be described in terms of the concentration difference between oil and water, we introduce a scalar order parameter ϕ which locally measures this difference. A Ginzburg–Landau model [36] then yields for the free energy a functional of the form

$$\mathcal{F}(\phi) = \int_{R^3} \bigl(g_0(\nabla\phi)^2 + f(\phi) - \mu\phi\bigr)\,\mathrm{d}r. \tag{6.1}$$

The function f is the free-energy density and μ is the chemical potential difference between oil and water. The free-energy density f is usually approximated by an even (due to the symmetry under the interchange of the two components) fourth order polynomial

$$f(\phi) = a_2\phi^2 + a_4\phi^4.$$

Thermodynamic stability of homogeneous phases requires that $a_4 > 0$. When $a_2 < 0$, there is coexistence of water-rich and oil-rich phases at $\mu = 0$, i.e. the two phases are at the same level of energy.

The addition of an amphiphile into the fluid can provoke the formation of wealth of complex self-assembled structures. An amphiphilic molecule consists of a polarizable head which prefers the highly polarizable water environment and a hydrocarbon tail which prefers the oil. The energy of the amphiphile is lowest when it can find or create surfaces between oil and water at which it can adsorb the other two components into various structures. Adding a small amount of amphiphile to the fluid will not in general modify the two-phase coexistence. The added amphiphile will partition itself between the two phases. On the other hand, if for example the amphiphile is more present in the water phase, a third phase can be made to appear by changing an external field such as the temperature or the chemical potential of a fourth component. This new phase contains more of the amphiphile and less of water and oil than the other two. Its density will be intermediate between that of the water-rich and the oil-rich phases and will be therefore physically located between them. Hence it is called the middle-phase.

Let us come back for a while to the free energy functional (6.1) of the binary fluid oil-water. Thermodynamic quantities and correlation functions can be obtained by approximation methods in which the functional $\mathcal{F}$ is minimized in the space of functions which spatially connect the two phases. The minimizer ϕ is then the interfacial profile between the oil-rich and the water-rich phase at coexistence.

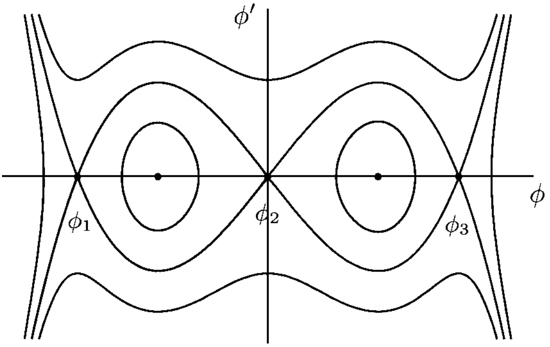

Fig. 3. The 3-stable system phase plane.

If we want to adapt the Ginzburg–Landau model (6.1) to describe the oil-water-amphiphile mixtures and keep a single order parameter which still measures the density difference between oil and water, we need to consider three-phase coexistence at $\mu = 0$ so that f must have three minima at $\phi_1 < \phi_2 < \phi_3$ corresponding respectively to the bulk phases oil-rich, middle and water-rich. Choosing their common value to be zero and assuming only one spatial dependence, the interfacial profile, $\phi(x)$, between the oil-rich phase which extends to $x \to -\infty$ and the water-rich phase which extends to $x \to +\infty$, then solves the equation

$$2g_0\phi'' - f'(\phi) = 0 \tag{6.2}$$

and the first integral

$$g_0\phi'(x)^2 - f\big(\phi(x)\big) = 0. \tag{6.3}$$

From a simple phase-plane analysis, see Fig. 3, it is easily seen that the only trajectory starting form ϕ_1 at $x \to -\infty$ and going to ϕ_3 at $x \to +\infty$ spends an infinite amount of time in ϕ_2, hence Eq. (6.2) has no solution ϕ satisfying $\phi(-\infty) = \phi_1$ and $\phi(+\infty) = \phi_3$. In the ternary mixture problem, this corresponds to an infinite thickness of middle phase, ϕ_2, between the oil-rich and water-rich phases. In other words, the model predicts the middle phase will always wet the interface between the oil- and water-rich phases, a prediction contrary to the results of experiment.

A simple way proposed by Gompper and Schick [36] to overcome this consequence of the model and yet consider a scalar order-parameter theory is to add a second order term in the Lagrangian, considering therefore the functional

$$\mathcal{F}(\phi) = \int_{R^3} \big(c\big(\nabla^2\phi\big)^2 + g(\phi)(\nabla\phi)^2 + f(\phi) - \mu\phi\big)\,\mathrm{d}r.$$

The function g, which quantifies the properties of the amphiphile, is negative close to the middle-phase as it tends to create interfaces and positive in the oil and water phases. The parameter c is positive and stabilizes the system.

The aim of this section is to prove that this last functional does not suffer the defect of the classical Ginzburg–Landau model (6.1) at least under some hypotheses on the nature of the middle-phase equilibrium. In the sequel, we only consider a scalar order-parameter ϕ with one spatial direction.

We consider a potential $f \in C^2(\mathbb{R})$ and a function $g \in C^2(\mathbb{R})$ satisfying (C1), (C4) and

(C2′) for some $0 < a < 1/2$ and $\alpha > 0$,

$$\frac{f(u)}{(u-1)^2} \leqslant \alpha, \quad \text{for } |u-1| < a,$$

$$\frac{f(u)}{(u+1)^2} \leqslant \alpha, \quad \text{for } |u+1| < a;$$

(C3′) $f(u) = 0$ if and only if $u = 0$ or $u = \pm 1$.

We also introduce the additional condition

$$g(0)^2 < 4f''(0).$$

This last condition implies that the trivial solution is a saddle-focus equilibrium for the linear equation

$$u'''' - g(0)u'' + f''(0)u = 0.$$

As observed in Section 5.1, if $g(0) < 0$ or (C1) holds with $g = \tilde{g}$, we just need f to be C^2 in a neighborhood of 0 and $f''(0) \neq 0$ as the inequality $g(0)^2 < 4f''(0)$ then holds.

Under the previous assumptions, it makes sense to consider the functional

$$\mathcal{F}(u) = \int_{-\infty}^{+\infty} \left(\frac{1}{2}\big(u''^2 + g(u)u'^2\big) + f(u) \right) \mathrm{d}x \tag{6.4}$$

in the space

$$\mathcal{H} := \left\{ u \in C^1(\mathbb{R}),\ u'' \in L^2(\mathbb{R}),\ u' \in L^\infty(\mathbb{R}) \text{ and } \lim_{x \to \pm\infty} u(x) = \pm 1 \right\}$$

and the associated Euler–Lagrange equation is given by

$$u'''' - g(u)u'' - \frac{1}{2}g'(u)u'^2 + f'(u) = 0. \tag{6.5}$$

Arguing as in Section 5, we observe that the functional (6.4) is bounded from below in $\mathcal{H}$.

LEMMA 6.1. *If f, $g \in C(\mathbb{R})$ satisfy* (C1), *then there exists a constant $s > 0$ such that for all $u \in \mathcal{H}$*

$$\mathcal{F}(u) \geqslant s \int_{-\infty}^{+\infty} \left(\frac{u''^2}{2} + f(u) \right) \mathrm{d}x.$$

The main theorem of the section goes as follows.

THEOREM 6.2. *Suppose that* $f, g \in C^2(\mathbb{R})$ *satisfy* (C1), (C2′), (C3′) *and* (C4). *If* $g(0)^2 < 4f''(0)$, *there exists a minimizer* u *of* $\mathcal{F}$ *in* $\mathcal{H}$ *which is a solution of* (6.5).

In comparison with Theorem 5.2, the additional condition $g(0)^2 < 4f''(0)$ allows to consider a potential f with a third bottom at 0. We do not know if Theorem 6.2 holds without this assumption.

The idea of the proof of Theorem 6.2 is identical to that of Theorem 5.2. We thus search for a control on the time it takes for a quasi-minimizer to travel from a neighborhood of $(-1, 0)$ to a neighborhood of $(+1, 0)$ in the uu'-plane. Observe that the presence of the third zero of the potential rules out some of the arguments used in the proof of Theorem 5.2. On the other hand, we easily obtain a control on time intervals from $(-1, 0)$ to $(0, 0)$ and $(0, 0)$ to $(+1, 0)$. To complete the arguments, we just need a control on the time quasi-minimizers spend close to 0. This control is obtained thanks to the additional condition that 0 is a saddle-focus. Basically, we show in Section 6.1 that due to the nature of the equilibrium, the local minimizers of (6.4) close to 0 (in the phase space) change sign in every interval of length larger than a fixed constant. We then introduce in Section 6.2 a *clipping* procedure which roughly speaking ensures that the quasi-minimizers are monotonic close to 0. This technique was first used by Kalies et al. [42]. The local analysis close to 0 then implies that quasi-minimizers do not spend much time close to 0. We give the proof of Theorem 6.2 in Section 6.3.

6.1. *Local analysis of a saddle-focus equilibrium*

We now focus on the local minimizers close to a saddle-focus equilibrium. To fix the ideas and to simplify the notation, we assume that f is a potential for which 0 is a nondegenerate global minimum and g is such that 0 is a saddle focus equilibrium of the linear equation

$$u'''' - g(0)u'' + f''(0)u = 0, \tag{6.6}$$

i.e. $g(0)^2 < 4f''(0)$. Basically, the following lemma shows that the minimizers of the functional

$$\mathcal{F}_{[a,b]}(u) := \int_a^b \left(\frac{1}{2}\left(\left(u''^2\right) + g(u)u'^2\right) + f(u)\right) \mathrm{d}x \tag{6.7}$$

on the set

$$\mathcal{H}_{a,b} := \left\{v \in H^2(a, b) \;\middle|\; \left(u(a), u'(a)\right) = y_0 \text{ and } \left(u(b), u'(b)\right) = y_1\right\}$$

are small (for the C^3-norm) whenever y_0 and y_1 are small. It then follows that the oscillatory behaviour of the solutions of the linearization (6.6) around the equilibrium extends to these minimizers. The following lemma is adapted from Theorem 4.1 [42] where it is assumed that g is positive.

LEMMA 6.3. *Let f and $g \in C^2(\mathbb{R})$ be such that $f(u) \geqslant 0$ for all $u \in \mathbb{R}$, $f(0) = f'(0) = 0$ and assume* (C1) *holds. Assume moreover that $f''(0) \neq 0$. Then, there exist $\delta_0 > 0$ and $S > 1$ such that if $b - a \geqslant 1$, $\|y_0\| \leqslant \delta_0$, $\|y_1\| \leqslant \delta_0$ and u minimizes $\mathcal{F}_{[a,b]}$ on $\mathcal{H}_{a,b}$, we have*

$$\|u\|_{C^3([a,b])} \leqslant S \max\bigl(\|y_0\|, \|y_1\|\bigr). \tag{6.8}$$

PROOF. As 0 is a nondegenerate minimum of f, there exist $\delta_0 > 0$, $\eta > 0$ and $\zeta > 0$ such that $|f'(u)| \leqslant 2\eta|u|$ and $\zeta u^2 \leqslant f(u) \leqslant \eta u^2$ for $|u| \leqslant \delta_0$. Notice also that using integration by parts and arguing as in Lemma 5.1, we see that there exists $s > 0$ such that for any function $u \in H^2(a, b)$,

$$\mathcal{F}_{[a,b]}(u) \geqslant s \int_a^b \left(\frac{u''^2}{2} + f(u)\right) \mathrm{d}x + \frac{1}{2}\bigl(\tilde{G}\bigl(u(b)\bigr)u'(b) - \tilde{G}\bigl(u(a)\bigr)u'(a)\bigr), \tag{6.9}$$

so that $\mathcal{F}_{[a,b]}$ is bounded from below on $\mathcal{H}_{a,b}$. The existence of a minimizer follows by standard arguments. Moreover, if u is a minimizer, u solves (6.5) on $[a, b]$ and satisfies the boundary conditions $(u(a), u'(a)) = y_0$ and $(u(b), u'(b)) = y_1$.

CLAIM 1. *There exists $C_1 > 0$ and $\delta_1 > 0$ such that if $\|y_0\| \leqslant \delta \leqslant \delta_1$ and $\|y_1\| \leqslant \delta \leqslant \delta_1$, then $\inf_{\mathcal{H}_{a,b}} \mathcal{F}_{[a,b]} \leqslant C_1\delta^2$.*

Define $P(x)$ as follows:

$$P(x) = \begin{cases} P_0(x) & \text{if } a \leqslant x \leqslant a + \frac{1}{2}, \\ 0 & \text{if } a + \frac{1}{2} < x \leqslant b - \frac{1}{2}, \\ P_1(x) & \text{if } b - \frac{1}{2} < x \leqslant b, \end{cases}$$

where P_i, $i = 0, 1$, are the third degree polynomials satisfying $(P_0(a), P_0'(a)) = y_0$, $(P_1(b), P_1'(b)) = y_1$ and $(P_0(a + \frac{1}{2}), P_0'(a + \frac{1}{2})) = (P_1(b - \frac{1}{2}), P_1'(b - \frac{1}{2})) = (0, 0)$. Observe that there exists $0 < \delta_1 \leqslant \delta_0$ such that if $\|y_0\| \leqslant \delta \leqslant \delta_1$ and $\|y_1\| \leqslant \delta \leqslant \delta_1$, then $\|P\|_{L^\infty} \leqslant \delta_0$. It then follows from an easy computation that

$$\inf_{\mathcal{H}_{a,b}} \mathcal{F}_{[a,b]} \leqslant \mathcal{F}_{[a,b]}(P) \leqslant C_1\delta^2,$$

where $C_1 > 0$ essentially depends on η and $\|g\|_{L^\infty(-\delta_0,\delta_0)}$.

CLAIM 2. *There exists $\delta_2 > 0$ such that if u is a minimizer in $\mathcal{H}_{a,b}$ with $\|y_0\| \leqslant \delta_2$ and $\|y_1\| \leqslant \delta_2$, then $\|u\|_\infty \leqslant \delta_0$.*

The ideas we use to prove the claim are already included in the proof of Proposition 5.3. Observe that the minimizers of $\mathcal{F}_{[a,b]}$ in $\mathcal{H}_{a,b}$ are a priori bounded in $C^1([a, b])$. Indeed, this follows easily arguing as in the first part of the proof of Proposition 5.3. We denote by L the C^1-bound. Consider next the set

$$\mathcal{D}_{a,b} := \{u \in \mathcal{H}_{a,b} \mid \text{ for all } x \in [a,b], |u(x)| \leqslant \delta_0\}.$$

Let us fix the notation $N_{\delta_0} := [-\delta_0, \delta_0]$. We then define

$$\mu := \min\{f(u) \mid u \in N_{\delta_0} \setminus N_{\delta_0/2}\} > 0,$$
$$\nu := \max\{|\tilde{G}(u)| \mid u \in N_{\delta_0}\} \geqslant 0.$$

As in Part 2—Step 2 of the proof of Proposition 5.3, we can derive a lower estimate on the action of functions $u \in \mathcal{H}_{a,b}$ whose graphs do not stay in the strip $[a,b] \times N_{\delta_0}$. Indeed, suppose $u \in \mathcal{H}_{a,b} \setminus \mathcal{D}_{a,b}$ minimizes $\mathcal{F}_{[a,b]}$ in $\mathcal{H}_{a,b}$ with $\|y_0\| \leqslant \delta \leqslant \delta_1$ and $\|y_1\| \leqslant \delta \leqslant \delta_1$. Then

$$\mathcal{F}_{[a,b]}(u) \geqslant \frac{s\mu\delta_0}{2L} - \nu\delta. \tag{6.10}$$

On the other hand, we infer from Claim 1 that

$$\mathcal{F}_{[a,b]}(u) \leqslant C_1\delta^2.$$

Choosing $\delta_2 > 0$ small enough and $0 < \delta \leqslant \delta_2$, the estimate (6.10) yields a contradiction so that $u \in \mathcal{D}_{a,b}$ and the claim follows.

CLAIM 3. *There exists $C_2 > 0$ such that if u is a minimizer in $\mathcal{H}_{a,b}$ with $\|y_0\| \leqslant \delta \leqslant \delta_2$ and $\|y_1\| \leqslant \delta \leqslant \delta_2$, then $\|u\|_{C^3} \leqslant C_2\delta$.*

Assuming that $\|y_0\| \leqslant \delta \leqslant \delta_2$ and $\|y_1\| \leqslant \delta \leqslant \delta_2$, we deduce from the estimate (6.9) that

$$\|u\|_{L^2} \leqslant C\delta \quad \text{and} \quad \|u''\|_{L^2} \leqslant C\delta.$$

Indeed, the L^2-bound for u'' follows easily while for the bound on u, it is sufficient to observe that f is bounded from below by the parabola ζu^2 for $|u| \leqslant \delta_0$. We now deduce by interpolation that

$$\|u'\|_{L^2} \leqslant C(\|u\|_{L^2} + \|u''\|_{L^2}) \leqslant C\delta.$$

The constant C can be chosen independent of the length $b-a$ as far as $b-a \geqslant 1$, see [1]. Using the continuous injection of $H^2(a,b)$ into $C^1([a,b])$, we deduce that

$$\|u\|_{C^1} \leqslant C\delta.$$

Observe that we can still choose a constant C that does not depend on the length of $[a,b]$ as $b-a \geqslant 1$. The differential equation (6.5) then yields the estimate

$$\|u''''\|_{L^2} \leqslant C\delta$$

so that by interpolation we also have

$$\|u'''\|_{L^2} \leqslant C\delta.$$

Now, the bound in C^3 follows from the bound in H^4 and the continuous injection in C^3. □

LEMMA 6.4. *Suppose that the assumptions of Lemma* 6.3 *hold and assume furthermore that* $g(0)^2 < 4f''(0)$. *Then there exist* $\delta_0 > 0$ *and* $\tau_0 > 0$ *such that if* $b - a \geqslant 1$, $\|y_0\| \leqslant \delta_0$, $\|y_1\| \leqslant \delta_0$, $\max(\|y_0\|, \|y_1\|) > 0$ *and* u *minimizes* $\mathcal{F}_{[a,b]}$ *on* $\mathcal{H}_{a,b}$, u *changes sign on every subinterval of* $[a, b]$ *having length larger than* τ_0.

The proof is included in Theorem 4.2 in [42]. A slight modification of Lemma 5.9 also leads to the conclusion. It is easily seen that the assumption on the convergence of the solution to the equilibrium in Lemma 5.9 can be replaced by a condition ensuring that the solution remains close (for the C^3-norm) to 0. Here, thanks to Lemma 6.3, the smallness of the boundary conditions on u and u' suffices to obtain such a control.

6.2. *Clipping*

Next, we recall the *clipping* procedure as introduced in [42]. When minimizing a functional in a certain space, we often want to be able to modify locally any function by another one being in the same space, having better properties and lower action. When dealing with a second order equation and its associated functional, we usually only have to worry about keeping functions continuous so that pieces of graph can be easily discarded. As our functional $\mathcal{F}$ requires square integrable second order derivative, things are more complicated. For example, any modification has to keep the functions at least C^1. Let us describe admissible cutoffs.

DEFINITION 6.5. Let $u \in C^1[a, b]$. If $u(\alpha) = u(\beta)$ and $u'(\alpha) = u'(\beta)$ for some $\alpha < \beta$ in $[a, b]$, we say that the interval $[\alpha, \beta]$ can be *clipped out* meaning that we can define a C^1 function $\hat{u}$ on the interval $[a, b - (\beta - \alpha)]$ which coincides with u and the $\beta - \alpha$ translate of $u_{|[\beta,b]}$ respectively on the intervals $[a, \alpha]$ and $[\alpha, b - (\beta - \alpha)]$. The function $\hat{u}$ is defined by

$$\hat{u}(x) := \begin{cases} u(x) & \text{if } x \in [a, \alpha], \\ u(x + \beta - \alpha) & \text{if } x \in \bigl[\alpha, b - (\beta - \alpha)\bigr]. \end{cases}$$

We say that $\hat{u}$ is a *clip* of u.

Observe that in case the Lagrangian

$$L_g\bigl(u, u', u''\bigr) = \frac{1}{2}\bigl(u''^2 + g(u)u'^2\bigr) + f(u)$$

is positive, the clipping process has the nice property that if $u \in \mathcal{H}$ and $\hat{u}$ is a clip of u, then

$$\mathcal{F}(\hat{u}) \leqslant \mathcal{F}(u).$$

When $L_g(u, u', u'')$ changes sign, this is no more true. However, we show below in Lemma 6.7 that under the assumption (C1), the clipping process decreases the action.

The following lemma gives the basic tool for clipping functions. It generalizes Lemma 3.1 in [42].

LEMMA 6.6. *Let $s_1 < s_2 < s_3 < s_4$ and let $u \in C^1(s_1, s_4)$ be such that*

$$u(s_1) = u(s_3), \qquad u(s_2) = u(s_4), \qquad \bigl(u'(s_1) - u'(s_3)\bigr)\bigl(u'(s_2) - u'(s_4)\bigr) \leqslant 0.$$

Assume, moreover, that

$$u(s_1) < u(s) < u(s_2) \quad \textit{for all } s \in]s_1, s_2[,$$

and

$$u(s_3) < u(s) < u(s_4) \quad \textit{for all } s \in]s_3, s_4[.$$

Then there exist $\alpha \in [s_1, s_2]$, $\beta \in [s_3, s_4]$ such that the interval $[\alpha, \beta]$ can be clipped out.

PROOF. Consider the set

$$E := \bigl\{(x, y) \in [s_1, s_2] \times [s_3, s_4] \bigm| u(x) = u(y)\bigr\}.$$

It follows from degree arguments that there exists a connected set $H \subset E$ that contains (s_1, s_3) and (s_2, s_4). Next we define the function $\varphi : H \to \mathbb{R}$ by

$$\varphi(x, y) = u'(x) - u'(y).$$

Since

$$\varphi(s_1, s_3)\varphi(s_2, s_4) \leqslant 0,$$

the continuity of φ leads to the conclusion. □

A typical example where Lemma 6.6 applies is displayed in Fig. 4.

As we already mentioned, the clipping procedure plays a key role to control and modify minimizing sequences. We therefore need to check that any clip has a lower action than the original function. This is the case when (C1) holds.

LEMMA 6.7. *Suppose that $f \in C(\mathbb{R})$ is a nonnegative function and $g \in C(\mathbb{R})$ satisfies* (C1). *If $u \in H^2(a, b)$ and $\hat{u} \in H^2(a, b - (\beta - \alpha))$ is a clip of u, then*

$$\mathcal{F}_{[a, b-(\beta-\alpha)]}(\hat{u}) \leqslant \mathcal{F}_{[a,b]}(u),$$

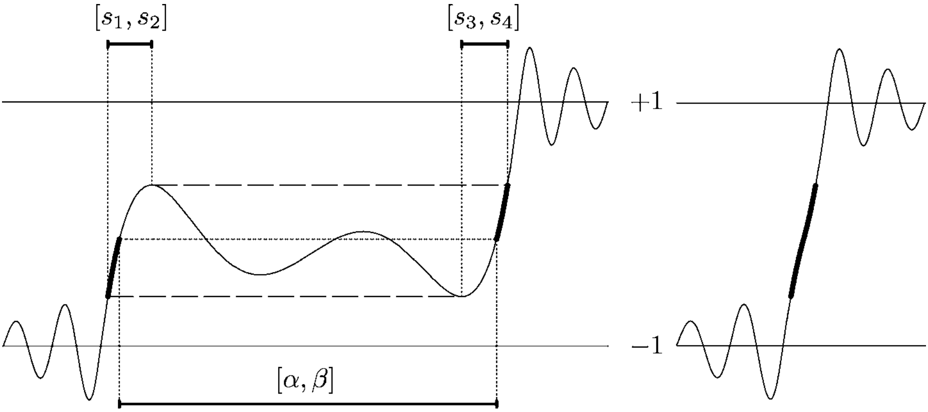

Fig. 4. *The clipping process*. Lemma 6.6 applies with $s_1 < s_2 < s_3 < s_4$ so that a subinterval $[\alpha, \beta]$ can be clipped out.

where $\mathcal{F}_{[a,b]}$ *is defined by* (6.7).

PROOF. We compute

$$\mathcal{F}_{[a,b-(\beta-\alpha)]}(\hat{u}) = \mathcal{F}_{[a,\alpha]}(u) + \mathcal{F}_{[\beta,b]}(u) = \mathcal{F}_{[a,b]}(u) - \mathcal{F}_{[\alpha,\beta]}(u)$$

and arguing as in Lemma 5.1, we infer that

$$\mathcal{F}_{[\alpha,\beta]}(u) \geqslant s \int_{\alpha}^{\beta} \left(\frac{u''^2}{2} + f(u) \right) \mathrm{d}x + \frac{1}{2}\big(\tilde{G}\big(u(\beta)\big)u'(\beta) - \tilde{G}\big(u(\alpha)\big)u'(\alpha)\big).$$

Since $u(\alpha) = u(\beta)$, $u'(\alpha) = u'(\beta)$, we obtain the inequality

$$\mathcal{F}_{[\alpha,\beta]}(u) \geqslant 0$$

so that the result follows. □

6.3. *Existence of a minimizer*

As for Theorem 5.2, the proof of Theorem 6.2 relies on the control and the localization of a minimizing sequence.

PROPOSITION 6.8. *Suppose that* $f, g \in C^2(\mathbb{R})$ *satisfy* (C1), (C2′), (C3′) *and* (C4). *Then there exists* $L > 0$, $T > 0$ *and a sequence* $(u_n)_{n\in\mathbb{N}} \subset \mathcal{H}$ *such that* $\mathcal{F}(u_n) \to \inf_{\mathcal{H}} \mathcal{F}$ *and for all* $n \in \mathbb{N}$,

(i) $\|u_n\|_{C^1} \leqslant L$,

(ii) $|u_n(x)+1| \leqslant a$ *for all* $x \leqslant -T$ *and* $|u_n(x)-1| \leqslant a$ *for all* $x \geqslant T$.

The proof of property (i) follows exactly the lines of the proof of Proposition 5.3, Part 1. We divide the proof of the second statement in three main steps. In Step 1, we approximate the minimum of $\mathcal{F}$ with functions that stay close to ± 1 at $\pm\infty$. Step 2 estimates the time for a function $u \in \mathcal{H}$ to travel in the (u, u')-plane from neighborhoods of $(\pm 1, 0)$ to a neighborhood of $(0, 0)$. Finally, in Step 3, we show that functions in $\mathcal{H}$ that stay close to 0 with small velocity can be replaced, using the clipping procedure, by functions that spend in such a neighborhood a time which is a priori bounded.

PROOF. The proof of the first statement has been worked out in the proof of Proposition 5.3. We therefore restrict our attention to the proof of the conclusion (ii).

Let $(u_n)_n \subset \mathcal{H}$ be a minimizing sequence for $\mathcal{F}$. We can assume without loss of generality that $\mathcal{F}(u_n) \leqslant C \leqslant \inf_{\mathcal{H}} \mathcal{F} + 1$. Let $\varepsilon > 0$ be fixed and such that $S\varepsilon \leqslant \delta_0$, where $\delta_0 > 0$ and $S > 1$ are given by Lemma 6.3 and Lemma 6.4. For each $n \in \mathbb{N}$, we define

$$x_1 := \sup\bigl\{x \mid \bigl|u_n(x)+1\bigr| \leqslant \varepsilon \text{ and } \bigl|u_n'(x)\bigr| \leqslant \varepsilon\bigr\},$$

and

$$x_4 := \inf\bigl\{x \mid \bigl|u_n(x)-1\bigr| \leqslant \varepsilon \text{ and } \bigl|u_n'(x)\bigr| \leqslant \varepsilon\bigr\}.$$

Step 1. Modification of u_n in $]-\infty, x_1]$ and $[x_4, \infty[$. For all $n \in \mathbb{N}$, there exists a function $v_n \in \mathcal{H}$ such that for all $x \leqslant x_1$, $|v_n(x)+1| \leqslant a$, for all $x \geqslant x_4$, $|v_n(x)-1| \leqslant a$ and $\mathcal{F}(v_n) \leqslant \mathcal{F}(u_n)$.

This step is similar to Part 2—Step 2 of the proof of Proposition 5.3 so that we skip it.

Step 2. Estimates on time intervals. Define for all $n \in \mathbb{N}$,

$$x_2 := \inf\bigl\{x \geqslant x_1 \mid \bigl|v_n(x)\bigr| \leqslant \varepsilon \text{ and } \bigl|v_n'(x)\bigr| \leqslant \varepsilon\bigr\}$$

and

$$x_3 := \sup\bigl\{x \leqslant x_4 \mid \bigl|v_n(x)\bigr| \leqslant \varepsilon \text{ and } \bigl|v_n'(x)\bigr| \leqslant \varepsilon\bigr\}.$$

Notice that x_2 and x_3 need not exist. Arguing as in Part 2—Step 1 of the proof of Proposition 5.3, we obtain a bound T_1 on $x_2 - x_1$ and $x_4 - x_3$, or on $x_4 - x_1$ if x_2 and x_3 do not exist.

Step 3. Modification in $[x_2, x_3]$. If x_2 and x_3 do not exist, this step can of course be skipped.

CLAIM 1. *For all* $n \in \mathbb{N}$, *there exists a function* w_n *which minimizes* $\mathcal{F}$ *in*

$$\mathcal{H}_{2,3} := \bigl\{w \in \mathcal{H} \mid w = v_n \text{ on } \mathbb{R} \setminus [x_2, x_3]\bigr\}.$$

Indeed, we can replace $v_n$by a minimizer of $\mathcal{F}$ in $\mathcal{H}_{2,3}$. Such a function w_n exists and satisfies $\mathcal{F}(w_n) \leqslant \mathcal{F}(v_n)$. Further, it solves the differential equation (6.5) on $[x_2, x_3]$ together with the boundary conditions

$$w_n(x_2) = v_n(x_2), \quad w_n'(x_2) = v_n'(x_2), \quad w_n(x_3) = v_n(x_3), \quad w_n'(x_3) = v_n'(x_3).$$

CLAIM 2. *For each $n \in \mathbb{N}$, if $x_3 - x_2 \geqslant \max(1, 8\tau_0)$, where τ_0 is given from Lemma* 6.4, *the function w_n can be replaced by a clip $\hat{w}_n \in \mathcal{H}$ so that after clipping the interval* $[x_1, x_4]$ *is transformed into an interval of length smaller than* $(x_2 - x_1) + \max(1, 8\tau_0) + (x_4 - x_3)$. *Further, we have $\mathcal{F}(\hat{w}_n) \leqslant \mathcal{F}(w_n)$.*

Define

$$x_2' := \max\bigl\{x \leqslant x_2 \bigm| |w_n(x)| = \delta_0\bigr\} \quad \text{and} \quad x_3' := \min\bigl\{x \geqslant x_3 \bigm| |w_n(x)| = \delta_0\bigr\}.$$

It follows from Claim 1 and Lemma 6.3 that $|w_n(x)| \leqslant S\varepsilon \leqslant \delta_0$ for all $x \in [x_2, x_3]$ and therefore also for all $x \in [x_2', x_3']$.

Suppose first that $w_n(x_2') = -\delta_0$ and $w_n(x_3') = \delta_0$. Define

$$\begin{aligned}
s_2 &:= \min\bigl\{x \in [x_2', x_3'] \bigm| w_n'(x) = 0 \text{ and } w_n(x) \geqslant 0\bigr\},\\
s_4 &:= \max\bigl\{x \in [x_2', x_3'] \bigm| w_n(x) = w_n(s_2)\bigr\},\\
s_3 &:= \max\bigl\{x \in [s_2, s_4] \bigm| w_n'(x) = 0\bigr\}
\end{aligned}$$

and take

$$s_1 := \max\bigl\{x \in [x_2', s_2] \bigm| w_n(x) = w_n(s_3)\bigr\}.$$

Observe that Lemma 6.4 ensures the existence of s_2 and moreover $s_2 \in [x_2', x_2 + 2\tau_0]$. Also, $s_3 \in [x_3 - 2\tau_0, x_3']$. Further, we can apply Lemma 6.6 to the function w_n on $[s_1, s_4]$ and discard the restriction of w_n to some interval $[\alpha, \beta]$ containing $[s_2, s_3]$. We denote by $\hat{w}_n$ the clip of w_n. Namely, we define

$$\hat{w}_n(x) := \begin{cases} w_n(x) & \text{if } x \in [a, \alpha],\\ w_n(x + \beta - \alpha) & \text{if } x \in \bigl(\alpha, b - (\beta - \alpha)\bigr). \end{cases}$$

Letting $x_4^* := x_4 - (\beta - \alpha)$, we have

$$x_4^* - x_1 \leqslant (x_4 - x_3) + 4\tau_0 + (x_2 - x_1).$$

If $w_n(x_2') = \delta_0$ and $w_n(x_3') = -\delta_0$, we use the same argument.

Assume now that $w_n(x_2') = -\delta_0$ and $w_n(x_3') = -\delta_0$. Let $q \in [x_2', x_3']$ be such that $\max_{x \in [x_2', x_3']} w_n(x) = w_n(q)$. Notice that Lemma 6.4 implies $w_n(q) > 0$ and hence we can apply the preceding argument to each of the intervals $[x_2', q]$ and $[q, x_3']$. Here, denoting by x_4^{**} the point into which x_4 is transformed, we have after clipping, $x_4^{**} - x_1 \leqslant (x_4 - x_3) + 8\tau_0 + (x_2 - x_1)$.

The case $w_n(x_2') = \delta_0$ and $w_n(x_3') = \delta_0$ is handled similarly.

Conclusion of Step 3. For each $n \in \mathbb{N}$, there exists a function $\hat{w}_n \in \mathcal{H}$ ($\hat{w}_n = w_n$ if $x_3 - x_2 \leqslant \max(1, 8\tau_0)$) which satisfies $\mathcal{F}(\hat{w}_n) \leqslant \mathcal{F}(w_n)$ and

$$\begin{aligned} \left|\hat{w}_n(x) + 1\right| &\leqslant a \quad \text{for all } x \leqslant x_1, \\ \left|\hat{w}_n(x) - 1\right| &\leqslant a \quad \text{for all } x \geqslant x_4', \end{aligned}$$

for some $x_4' \in \mathbb{R}$ such that

$$x_4' - x_1 \leqslant 2T_1 + \max(1, 8\tau_0),$$

where T_1 is defined in Step 2.

Conclusion. Taking

$$T = T_1 + \frac{1}{2}\max(1, 8\tau_0)$$

and using a time-translation if necessary, we finally construct a minimizing sequence $(z_n)_n \subset \mathcal{H}$ that satisfies the second statement of Proposition 6.8. Notice that in case x_2 and x_3 are not defined, we can choose

$$T = \frac{T_1}{2} \geqslant \frac{1}{2}(x_4 - x_1). \qquad \square$$

Now that we have at hand a minimizing sequence satisfying Proposition 6.8, the proof of Theorem 6.2 follows the lines of the proof of Theorem 5.2.

6.4. *Notes and further comments*

1. As discussed in the first note of Section 5, the minimizer obtained in Theorem 6.2 is a heteroclinic solution in a weak sense.

2. Other Ginzburg–Landau models for ternary mixtures have been proposed in the literature, including two-order-parameter and three-order-parameter models, see [36]. In these models, a second scalar parameter ψ which describes the local concentration of amphiphile is introduced. Simple cases have been studied numerically by physicists but up to our knowledge the corresponding type of functional has not been treated mathematically.

7. Multi-transition connections

We consider again the case of a bi-stable equation. We already mentioned in Section 4.3 that when ±1 are saddle-focus equilibria, the extended Fisher–Kolmogorov equation (4.3) has infinitely many solutions that can be classified according to their homotopy type. In this section, we focus on multi-transition solutions which correspond to solutions of type $g = (g_1, \dots, g_n)$, $n \in \mathbb{N}_0$, with $g_i = 2$ for all $i = 1, \dots, n$.

Considering again the functional

$$\mathcal{F}(u) = \int_{-\infty}^{+\infty} \left(\frac{1}{2}\left(u''^2 + g(u)u'^2\right) + f(u)\right) \mathrm{d}x \tag{7.1}$$

whose Euler–Lagrange equation is given by

$$u'''' - g(u)u'' - \frac{1}{2}g'(u)u'^2 + f'(u) = 0, \tag{7.2}$$

we assume that the function f is a positive symmetric double-well potential with bottoms at ± 1 and g is an even function which is not necessarily constant. Since f and g are even, arguing as in Section 4.2, we can restrict our attention to odd solutions. We thus look at the critical points of the functional

$$\mathcal{F}^+(u) = \int_0^{+\infty} \left(\frac{1}{2}\left(u''^2 + g(u)u'^2\right) + f(u)\right) \mathrm{d}x \tag{7.3}$$

in the space

$$\mathcal{E}^+ = \left\{u \mid u - 1 \in H^2\left(\mathbb{R}^+\right), u(0) = 0\right\}. \tag{7.4}$$

If $\mathcal{F}^+$ has a minimizer u then $u''(0) = 0$ and extending u on $\mathbb{R}$ by

$$u^*(x) = \begin{cases} -u(-x) & \text{if } x < 0, \\ u(x) & \text{if } x \geqslant 0 \end{cases} \tag{7.5}$$

we obtain an odd solution of (7.2).

We expect multi-transition solutions when the equilibria ± 1 are saddle-foci, i.e. when $g(1)^2 < 4f''(1)$. We obtain these solutions by odd extension of local minima of the functional $\mathcal{F}^+$ in appropriate subsets of $\mathcal{E}^+$. Basically, these subsets correspond to classes of functions having the desired number of transitions. We define for each $n \geqslant 0$, the subset $\mathcal{E}_n^+ \subset \mathcal{E}^+$ consisting of functions whose odd extensions on $\mathbb{R}$ make $2n + 1$ transitions. More precisely, a function $u \in \mathcal{E}^+$ belongs to the subclass $\mathcal{E}_n^+$ if there exist $0 = x_0 < x_1 < \cdots < x_n < x_{n+1} = \infty$ such that

$$u(x)(-1)^{i+n} > 0 \quad \text{for } x \in (x_i, x_{i+1}),$$
$$\max_{(x_i, x_{i+1})} u(x)(-1)^{i+n} > 1.$$

We prove that $\mathcal{F}^+$ has a local minimum in each of these subspaces in the following situation.

THEOREM 7.1. *Let f and $g \in C^2(\mathbb{R})$ satisfy* (C1), (C3) *and* (C4). *Assume moreover that $g(1)^2 < 4f''(1)$. Then, for every $n \in \mathbb{N}$, $\mathcal{F}^+$ has in each subspace $\mathcal{E}_n^+$, a local minimizer u_n whose odd extension on $\mathbb{R}$ is a heteroclinic solution of* (1.8) *having exactly* $2n+1$ *zeros.*

For a function $u \in \mathcal{E}_n^+$, we denote by I_i the intervals (x_i, x_{i+1}) for $i = 0, \dots, n$ where by convention $x_0 = 0$ and $x_{n+1} = \infty$. The main idea in the proof of Theorem 7.1 is to show the existence of a minimizing sequence $(u_p)_p \subset \mathcal{E}_n^+$ that has the following properties:

(a) there exists $I > 0$ such that for all u_p, $|I_i| \leqslant I$ for all $i = 0, \dots, n-1$;

(b) for all $\varepsilon > 0$, there exists $T > 0$ such that for all u_p, $|u_p(x) - 1| \leqslant \varepsilon$ for $x \geqslant T$.

These two properties are closely related as they prevent from a loss of compactness when extracting a weakly converging subsequence. We do not enter into the details of the proof of the existence of a minimizing sequence having properties (a) and (b). Indeed, the details are rather technical and do not bring new arguments with respect to the previous sections. The control on the length of the intervals I_i is obtained thanks to the clipping procedure discussed in Section 6.2 and the oscillatory behaviour of minimizers close to the equilibria ± 1 described in Section 6.1. The scheme of the arguments is as follows. Let us suppose to fix the ideas that u_p is positive on the interval I_i. As the assumptions of Lemma 5.1 hold, the second derivative and the potential are the significant terms in $\mathcal{F}^+$. An analysis similar to that of Section 5.1 then shows that the only way for the I_i's to grow to infinity is that the u_p's stay on growing intervals in a neighborhood of $+1$. But in this case, arguing as in Step 3 of the proof of Proposition 6.8, we can locally replace u_p by a minimizer close to $+1$ and clip this minimizer to obtain a function which stays close to $+1$ in an a priori bounded interval. Once the minimizing sequence satisfies (a), the property (b) follows from the arguments of Section 5.1.

We now turn to the proof of Theorem 7.1. The main difficulty is to ensure that the minimizing sequence does not loose or gain complexity in the limit.

PROOF OF THEOREM 7.1.

Step 1. *Convergence*. Let $(u_p)_p \subset \mathcal{E}_n^+$ be a minimizing sequence for $\mathcal{F}^+$ that satisfies the properties (a) and (b). Arguing as in the previous sections, we infer that u_p converges in C^1_{loc} to some function $u \in \mathcal{E}^+$ which is such that

$$\mathcal{F}^+(u) \leqslant \inf_{\mathcal{E}_n^+} \mathcal{F}^+.$$

We denote the extremities of the intervals $I_i^{u_p}$ by x_i^p, $i = 0, \dots, n$. It is clear by uniform convergence that up to a subsequence, for all $i = 1, \dots, n$, x_i^p converges to some $x_i < T$. Remember that by convention, we set $x_0^p = x_0 = 0$ and $x_{n+1}^p = x_{n+1} = \infty$. We call I_i the intervals (x_i, x_{i+1}), $i = 0, \dots, n$. We also deduce from the convergence in $C^1([0, T])$ and the convergence in $C^1_{\text{loc}}([T, +\infty[)$ that

$$u(x)(-1)^{i+n} \geqslant 0 \quad \text{for } x \in (x_i, x_{i+1}),$$

$$\max_{(x_i, x_{i+1})} u(x)(-1)^{i+n} \geqslant 1.$$

Step 2. *Elimination of the zeros of u after x_n*. If u has zeros after x_n, we first modify it to keep only one of those zeros. So, suppose that u vanishes at least two times after x_n. We then define

$$a_1 := \min\{x > x_n \mid u(x) = 0\} \quad \text{and} \quad a_2 := \max\{x > x_n \mid u(x) = 0\}.$$

Since $u(a_1) = u(a_2) = u'(a_1) = u'(a_2) = 0$ by convergence in C^1_{loc}, the interval $[a_1, a_2]$ can be clipped out and the clip has only one zero after x_n. Of course this modification decreases the action.

Assume now that u vanishes at some point $\xi > x_n$. We then have $u'(\xi) = 0$. Now as $u(x_n) = u(\xi)$, there exists at least one critical point y between x_n and ξ such that $u(y) > 0$. Here, we have two possibilities, either y can be taken in such a way that $u(y) \leqslant 1$ or [0, 1] does not contain any critical value of $u_{|[x_n,\xi]}$.

Suppose first that we can find $y \in (x_n, \xi)$ such that $0 < u(y) \leqslant 1$ and $u'(y) = 0$. As $u \in \mathcal{E}^+$,

$$\lim_{x\to\infty} \big(u(x), u'(x)\big) = (1, 0).$$

Hence, by an argument similar to that of the proof of Lemma 6.4, we see that $u(x)$ oscillates around 1 for x large enough. Therefore, we can clip out an interval containing $[y, \xi]$ in such a way that the clip of u does not vanish after x_n.

In the second case, we can find $y \in (x_n, \xi)$ such that $u(y) > 1$ and if $x \in (x_n, \xi)$ satisfies $u'(x) = 0$, then $u(x) > 1$. We now define $v \in \mathcal{E}^+$ by

$$v(x) := \begin{cases} -u(x + x_1) & \text{if } 0 \leqslant x \leqslant \xi - x_1, \\ u(x + x_1) & \text{if } x > \xi - x_1. \end{cases}$$

Observe that since $\min_{[x_n - x_1, \xi - x_1]} v(x) < -1$ and v is negative in $(x_n - x_1, \xi - x_1)$, v has the right number of transitions. Also, v does not vanish after $\xi - x_1$. On the other hand, we deduce from Lemma 5.1 that

$$\int_{x_0}^{x_1} \left(\frac{1}{2}\big(u''^2 + g(u)u'^2\big) + f(u)\right) \mathrm{d}x \geqslant 0$$

so that $\mathcal{F}^+(v) \leqslant \mathcal{F}^+(u)$.

Step 3. *Elimination of the zeros of v in the bumps*. We still denote by $0 = x_0 < x_1 < \cdots < x_n$, the extremities of the intervals I_i associated to v (actually, these are the intervals I_i which have possibly been translated in Step 2). Suppose that there exists $\xi \in v^{-1}(0)$ so that $\xi \neq x_i$ for any $i = 0, \ldots, n$. Hence, ξ lies in the interior of an interval I_i. To fix the ideas, we assume that v is nonnegative therein and denoting by $v(\bar{x}_i)$ the maximum of v over this interval we assume that ξ is at the left of $\bar{x}_i$. Next, define $\xi_1 = \min\{x > x_i \mid v(x) = 0\}$ and $\xi_2 = \max\{x \in [\xi_1, \bar{x}_i] \mid v(x) = 0\}$. It is easily seen that an interval containing $[\xi_1, \xi_2]$ can be clipped out so that the zeros can be deleted.

Step 4. *Elimination of the tangencies with* ±1. The last condition that we have to check to be sure that $v \in \mathcal{E}_n^+$ is that

$$\max_{x\in I_i}\left|v(x)\right| > 1$$

for all $i = 0, \dots, n$. Assume that this condition fails to be true in one of the intervals I_i. In this interval, we thus have $\max_{x\in I_i} |v(x)| = 1$. Let $\tau \in I_i$ be such that $|v(\tau)| = 1$ and $v'(\tau) = 0$. To fix the ideas, assume that $v(\tau) = 1$, the second case being treated in the same way. Let τ_0 and δ_0 be given by Lemma 6.4. As the action of the function 1 is zero, we can modify v without increasing its action by stretching the point τ to an interval of arbitrary length and gluing the function 1 to both extremities, see [42]. Now, we take a_1, (respectively a_2) at the left (respectively at the right) of τ in such a way that $0 < \max_{i=1,2} \|(v(a_i) - 1, v'(a_i))\| \leqslant \delta_0$ and stretch τ to an interval of length τ_0. We still call v the function obtained after gluing 1 at τ and $\tau + \tau_0$. It follows from Lemma 6.4 that the minimizers of

$$\int_{a_1}^{a_2+\tau_0}\left(\frac{1}{2}\left(u''^2 + g(u)u'^2\right) + f(u)\right)\mathrm{d}x$$

on the set of functions $u \in H^2(a_1, \tau_0 + a_2)$ that satisfy $u(a_1) = v(a_1)$, $u'(a_1) = v'(a_1)$, $u(a_2 + \tau_0) = v(a_2)$ and $u'(a_2 + \tau_0) = v'(a_2)$ oscillate around 1. If we replace v locally by a minimizer, we obtain a new function w such that

$$\max_{x\in I_i}\left|w(x)\right| > 1$$

and $\mathcal{F}^+(w) \leqslant \mathcal{F}^+(v)$.

Conclusion. It follows from the previous steps that we can construct $w \in \mathcal{E}_n^+$ such that $\mathcal{F}^+(w) \leqslant \mathcal{F}^+(u)$. Consequently, we have $\mathcal{F}^+(w) = \inf_{\mathcal{E}_n} \mathcal{F}^+$. Now observe that for all $h \in H^2(\mathbb{R}^+)$ such that $h(0) = 0$, $\mathcal{F}^+(w) \leqslant \mathcal{F}^+(w + th)$ for t sufficiently small. Indeed, assume that there exists a sequence $(t_n)_n$ tending to 0 such that $\mathcal{F}^+(w) > \mathcal{F}^+(w + t_n h)$. If w is in the interior of the class $\mathcal{E}_n^+$, this is obviously a contradiction. In the case where w is on the boundary of $\mathcal{E}_n^+$ i.e. if for some points x_i, $w(x_i) = w'(x_i) = 0$, then even for t small, $w + th$ can have more than one zero close to the x_i's so that it does not belong necessarily to $\mathcal{E}_n^+$. However for t small enough, $w + th$ has the right number of transitions and the oscillations close to the points x_i can be erased using the clipping procedure. Therefore, for n large enough, modifying $w + t_n h$ close to the x_i's if necessary, we obtain a function in $\mathcal{E}_n^+$ whose action is strictly smaller than $\mathcal{F}^+(w)$. This contradicts the definition of w and therefore w is a critical point of $\mathcal{F}^+$ in $\mathcal{E}_n^+$. Finally, we infer from the conservation of the Hamiltonian

$$H\left(u, u', u'', u'''\right) = u'''u' - \frac{1}{2}u''^2 - \frac{1}{2}g(u)u'^2 + f(u)$$

that each minimizer is actually in the interior of $\mathcal{E}_n^+$, i.e. each crossing with zero is transverse. □

7.1. *Notes and further comments*

1. Theorem 7.1 can be seen as a partial extension of the results of [42] to Lagrangians that can take either signs. To deal with such Lagrangians, we only require an a priori lower bound on the action along admissible functions. In Theorem 7.1, this lower bound follows from assumption (C1). The conclusion of Theorem 7.1 holds also with the settings of Theorem 5.7, see [18]. In this case we explicitly assume that the functional is bounded from below.

2. Multi-transition solutions can also be obtained in the case of multi-well potentials. We can for example consider the framework of Section 6 assuming then that each equilibrium is of saddle-focus type.

3. The abundance of local minima suggests the existence of infinitely many other critical points of minimax type. However the lack of a compactness property of the Palais–Smale sequences makes the investigation of such solution very complicate. It would seem rather natural that a solution obtained from a minimax principle based on deformations from one local minimum to another one, behaves like the single-transition solutions obtained in Theorem 4.4 for $\beta \geqslant 0$. Even for this range of β, the variational nature of the single-transition solutions is unknown. D. Smets and J.B. van den Berg have used in [83] a modified functional and mountain-pass arguments to catch a homoclinic solution of the Swift–Hohenberg equation for almost every $\beta \in\,]-\sqrt{8}, 0[$.

Preface

The method of lower and upper solutions is an elementary but powerful tool in the existence theory of initial and periodic problems for semilinear differential equations for which a maximum principle holds, even in cases where no special structure is assumed on the nonlinearity (see, e.g., [150,118,112,39,41,117,98]). The aim of this work is to show that this method is also quite effective for investigating the qualitative properties of solutions, at the same extent of generality for which the existence theory is developed. Indeed, our main purpose is to work out, under a minimal set of basic assumptions, a qualitative theory for two sample classes of scalar periodic differential equations: the first order ordinary differential equation

$$u' = f(t, u) \tag{1}$$

and the second order parabolic problem

$$\begin{aligned} &\partial_t u + A(x, t, \partial_x)u = f(x, t, u, \nabla_x u) && \text{in } \Omega \times I, \\ &u = 0 && \text{on } \partial\Omega \times I. \end{aligned} \tag{2}$$

Here $I \subseteq \mathbb{R}$ is an interval, $\Omega \subset \mathbb{R}^N$ is a bounded smooth domain, $\partial_t u + A(x, t, \partial_x)u$ is a uniformly parabolic differential operator, with time-periodic coefficients, and the functions f are time-periodic and satisfy suitable Carathéodory conditions. We must stress that under these assumptions neither uniqueness for the initial value problem associated with (1) and (2), nor validity of comparison principles are guaranteed. Accordingly, the qualitative analysis of these equations cannot be performed applying the theory of order preserving dynamical systems as given, for instance, in [60]. In this general setting we will actually ascertain, already for the easy-looking equation (1) and unlike the regular case, the occurrence of very complicated dynamics, so that even the explicit knowledge of a distinguished class of solutions (such as equilibria, or periodic solutions) is generally not sufficient to get a global qualitative portrait.

We are especially interested here in studying, with the aid of lower and upper solutions, the following three basic questions about (1) and (2):

(i) existence of periodic solutions of (1), or (2), and their localization;

(ii) qualitative properties of periodic solutions of (1), or (2), with special reference to their stability or instability;

(iii) asymptotic behaviour of solutions of the initial value problem associated with (1), or (2).

This program is pursued in the first part of this work for (1) and in the second part for (2); however, as it is quite predictable, exhaustive results can be obtained only for (1). Problems (1) and (2) share relevant similarities from the qualitative point of view. In fact Eq. (2) looks like a natural extension of (1), which in turn represents a simple, but nontrivial, paradigm of the patterns that can be possibly displayed by the dynamics of (2). Nevertheless, they exhibit several differences, which appear already evident developing the existence theory for the initial and the periodic problems in the presence of lower and upper solutions. Hence the two equations require separate treatments. We chose to describe here just basic results and to select a small number of examples or applications; further material can be found in [112] for (1) and in [42] for (2).

Although the method of lower and upper solutions applies to a larger class of boundary value problems, we decided to restrict our attention to the above two ones only. In particular, a remarkable topic which is completely left out here concerns the second order periodic ordinary differential equation

$$u'' = f\bigl(t, u, u'\bigr) \quad \text{on } I. \tag{3}$$

In this context a theory of the stability of periodic solutions, exploiting lower and upper solutions, started in [72] and has been recently developed in [116,36,111,109]. This omission is however not only dictated by the necessity of keeping our work within a reasonable length, but it is also motivated by the fact that the study of (3) relies on somewhat different techniques from the ones we use here; further, more regularity is required on f and at the moment the results are less complete.

1. First Order Periodic ODEs

1.1. *Introduction*

In this part we consider the first order scalar ordinary differential equation

$$x' = f(t, x). \tag{1.1}$$

We assume that $f : \mathbb{R} \times \mathbb{R} \to \mathbb{R}$ is periodic in t with period $T > 0$ and satisfies the L^1-Carathéodory conditions. Associated with (1.1), we consider the Cauchy problem

$$x' = f(t, x), \quad x(t_0) = x_0, \tag{1.2}$$

where $t_0, x_0 \in \mathbb{R}$ are given, and the periodic problem on $[0, T]$

$$x' = f(t, x), \quad x(0) = x(T). \tag{1.3}$$

Solutions of (1.1), (1.2), (1.3) are intended in the Carathéodory, i.e. $W^{1,1}_{\mathrm{loc}}$-, sense. Since any solution of (1.3) on $[0, T]$ extends to a T-periodic solution of (1.1), it will also be referred to as T-periodic.

Existence, multiplicity, localization and qualitative properties of solutions of (1.3) have been investigated using various approaches (see, e.g., [91,122,147,99,95,148,94,108,28, 142,113] and the included references). In particular, when f is a polynomial in x with coefficients T-periodic in t, the interest of the results that have been obtained stems from their connections with Hilbert Sixteenth Problem about the number of limit cycles of autonomous plane polynomial systems (see, e.g., [87,88,85,135,4,62,63,24]), or from their applications to the study of single species population models in a periodically fluctuating environment (see, e.g., [74,131,31,30,43,129,132,14,96,146,19,97]).

The knowledge of the T-periodic solutions of (1.1) is also the basic step in the realization of the Poincaré program, that is the determination of the qualitative portrait of all solutions of (1.1). If the property of uniqueness of solutions holds for the Cauchy problem (1.2), the behaviour of the solutions of scalar T-periodic differential equations such as (1.1) is, at least conceptually, nearly as simple as the behaviour of autonomous equations. Indeed, in this case the dynamics can be reduced to that of the Poincaré map, which assigns to every initial datum the value of the solution after one period, and, since this is strictly monotone, the orbit structure can be classified in an elementary way (cf. [57, Chapter 4]). In the Carathéodory setting, although generic (cf. [121, Chapter 3]), uniqueness in the future, or in the past, for the solutions of (1.2) is of course not anymore guaranteed. This fact yields evident technical complications also due to the possible failure of comparison principles for the solutions of (1.1). On the other hand, the lack of uniqueness entails, as we shall see, a rich variety of dynamics, such as the possible occurrence of homoclinic, subharmonic and almost periodic solutions. In addition to these theoretical features, that may justify by themselves a close analysis, further motivations for studying (1.1) in the absence of uniqueness come from some models in population dynamics related to those proposed by G.F. Gause in [53, Chapter VI].

The main purpose in this part of our work is to show that a quite satisfactory description of the dynamics of (1.1) can be performed in the Carathéodory setting by a systematic use of lower and upper solutions, i.e. functions satisfying suitable differential inequalities. The lower and upper solutions method is a classical tool for the study of (1.2) and (1.3) and it has already been employed by several authors since the pioneering work of G. Peano [119] (see [120,102,143,101,150,79,2,94,110,38,52,89,28] and the included references). Yet, while this approach has been largely used in the discussion of existence, multiplicity and approximation by monotone iteration, the stability properties of the solutions of (1.3) have been generally detected by other techniques, often based on linearization (see the recent papers [10,11,20,21] and the references therein). Partial exceptions are [95,96,133], where a global qualitative portrait of (1.1) was obtained, but only for a restricted class of functions f satisfying some convexity assumptions with respect to the x-variable, which in turn imply uniqueness of the solutions of (1.2). Of course, these methods do not apply to the general context we wish to discuss here, where Lipschitz or differentiability conditions on f are not required. Our work is therefore in the spirit of [147] and [112], whose declared aim was to pave the way towards a theory of periodic solutions of Eq. (1.1) when no special structure is considered.

This part is organized as follows. In Section 1.2 we formalize some definitions concerning the first order scalar ordinary differential equation (1.1) as well as we settle some notations.

In Section 1.3 we collect some basic facts concerning the solvability in the Carathéodory setting of the Cauchy problem (1.2), when a pair of possibly discontinuous lower and upper solutions is given and no special ordering between them is assumed. Existence and localization of solutions, as well as the structure of the solution set, are discussed in this frame.

In Section 1.4 we initiate the qualitative study of solutions of (1.1). We first discuss a form of monotonicity over periods, named T-monotonicity, which, unlike the case where uniqueness holds for the Cauchy problem (1.2), is not shared by all solutions of (1.1). We prove, however, that T-monotonicity is enjoyed by every solution of (1.1) that is comparable with any possible solution of (1.3). This property represents an essential tool for the description of the asymptotic behaviour of solutions of (1.1). In particular, it allows to obtain an extension of the existence part of the classical Massera Convergence Theorem [91] to the case where uniqueness for (1.2) fails; that is, the existence of a bounded solution x of (1.1) defined on an unbounded interval implies the existence of a T-periodic solution u of (1.1). A different proof of this fact is given in [147], while a discussion of various extensions of the Massera Theorem can be found in [104]. Yet, in the absence of uniqueness for (1.2), x does not generally converge to u: an example where the convergence does not take place is explicitly produced. Afterwards, we prove a technical result which describes the dynamics of solutions stemming from a lower or an upper solution of (1.3). This result plays a central role in the subsequent study of the stability of T-periodic solutions; it resembles the Monotone Convergence Criterion in the theory of monotone maps and may have an independent interest, since it guarantees the convergence to a T-periodic solution of a bounded solution emanating from and lying above a lower solution or emanating from and lying below an upper solution of (1.3). Founded on these results, we prove the main existence and localization theorem for (1.2), under the assumption of the existence of a pair of possibly discontinuous and unordered lower and upper solutions. We also point out by an example how the type of discontinuous lower and upper solutions of (1.3) here considered can be successfully used, in some cases, to get precise information on the localization of branches of T-periodic solutions.

Section 1.5 deals with the description of the dynamics of solutions of (1.1), which lie between two strictly ordered T-periodic solutions, or above the maximum T-periodic solution, or below the minimum one, if they exist. In particular, we show the existence of heteroclinic solutions connecting pairs of ordered T-periodic solutions of (1.1), when there is no further T-periodic solution in between. These results are based on the T-monotonicity of solutions of (1.1), which are comparable with any possible solution of (1.3), and they yield information about the stability and instability of solutions of (1.3), also with reference to the existence of repulsivity and attractivity basins.

Section 1.6, which represents the core of this part, is devoted to the study of the stability properties of the T-periodic solutions of (1.1) by means of lower and upper solutions. We begin with a discussion of the mutual relations of three notions of one-sided stability of a T-periodic solution we believe appropriate to be considered when uniqueness for (1.2) may fail: Lyapunov stability, order stability and weak stability. The second one is standard in the frame of order preserving discrete-time semidynamical systems (cf. [58, 60]). The third one has been used in the context of multivalued semiflows (cf. [130,50]) and is related to the notion of weak invariance (cf. [105,152,140]). If uniqueness in the future, or in the past, holds for (1.2), then Lyapunov stability and order stability are equivalent concepts. Whereas, we show here that order stability and weak stability are always equivalent: thus weak stability yields an alternative and more direct interpretation of order stability, in terms of the dynamics of solutions of (1.1). Using these three notions we can describe in a precise way the stability properties of a T-periodic solution, relating them to the existence of a lower or an upper solution close to it. Hence, when a pair of lower and upper solutions is given, we can discuss the stability or instability of the minimum and the maximum T-periodic solutions v and w wedged between them. Afterwards, we turn to investigate the behaviour of the solutions lying between v and w. If the lower and the upper solutions satisfy the standard ordering condition, i.e. the lower solution is below the upper solution, we find between v and w a weakly stable T-periodic solution; whereas, in the complementary case, Lyapunov unstable T-periodic solutions always exist. We further study the existence and the properties of nondegenerate continua of T-periodic solutions in $C^0([0,T])$. In particular, we see that if two T-periodic solutions are not strictly ordered, they give rise to a nondegenerate continuum of unstable T-periodic solutions. This fact may occur in the presence of a pair of unordered lower and upper solutions of (1.3). On the contrary, the existence of a pair of lower and upper solutions of (1.3) satisfying the standard ordering condition always guarantees the existence of a totally ordered continuum of weakly stable solutions. More generally, we investigate the topological structure of the set of all solutions of (1.3). This set is the union of a family of mutually ordered connected components. In the absence of uniqueness for (1.2) we show that such components may have arbitrarily large (Čech–Lebesgue) dimension. Moreover, when a continuum $\mathcal{K}$ is generated by two T-periodic solutions which are not strictly ordered, the dynamics of the solutions of (1.1), which lie between the minimum and the maximum elements in $\mathcal{K}$, is fairly complicated. Loosely speaking, any discrete, even chaotic, dynamics can be realized (see [114]). In particular, we can find homoclinics, subharmonic solutions of any order and almost periodic solutions which are not periodic of any period. As it is well known [91], this phenomenon cannot take place if the uniqueness property holds for (1.2).

In Section 1.7 we revisit the Massera Convergence Theorem. We have already noticed in Section 1.4 that, even when uniqueness for (1.2) fails, the existence of a solution u of (1.3) is always guaranteed in the presence of a bounded solution x of (1.1) defined on an unbounded interval, in spite of the fact that x does not generally converge to u. In this section we make this statement more precise, providing a complete extension of the Massera Convergence Theorem to the case where the uniqueness assumption for solutions of (1.2) is dropped. Namely, we see that either x converges to u, or the set of all solutions u of (1.3), whose range contains ω-limit points of x, forms a nondegenerate closed connected set in $C^0([0,T])$.

1.2. *Preliminaries*

In this section we formalize some basic definitions concerning the first order scalar ordinary differential equation (1.1). Let $T > 0$ be a fixed number. The following condition is assumed:

(C) $f :]0,T[\times\mathbb{R} \to \mathbb{R}$ satisfies the L^1-Carathéodory conditions, i.e. for every $x \in \mathbb{R}$, $f(\cdot,x)$ is measurable on $]0,T[$; for a.e. $t \in]0,T[$, $f(t,\cdot)$ is continuous on $\mathbb{R}$; for each $\rho > 0$, there exists $\gamma \in L^1(0,T)$ such that $|f(t,x)| \leqslant \gamma(t)$, for a.e. $t \in]0,T[$ and every $x \in [-\rho,\rho]$.

REMARK 1.1. The function f is identified with its T-periodic extension onto $\mathbb{R} \times \mathbb{R}$.

Solutions and lower and upper solutions

DEFINITION 1.1.

- A *solution of* (1.1) *on* $[t_1, t_2]$, with $t_1, t_2 \in \mathbb{R}$ and $t_1 < t_2$, is a function $x \in W^{1,1}(t_1, t_2)$ such that

$$x'(t) = f\big(t, x(t)\big) \quad \text{a.e. on }]t_1, t_2[.$$

- A *solution of* (1.1) *on* J, where J is a noncompact interval having endpoints t_1, t_2, with $-\infty \leqslant t_1 < t_2 \leqslant +\infty$, is a function x such that, for every compact interval $K \subset J$, $u|_K$ is a solution of (1.1) on K.

DEFINITION 1.2. Let $I \subseteq \mathbb{R}$ be an interval having endpoints ω_-, ω_+, with $-\infty \leqslant \omega_- < \omega_+ \leqslant +\infty$. A solution $x : I \to \mathbb{R}$ of (1.1) is said *right-nonextendible* if either $\omega_+ = +\infty$, or $\omega_+ < +\infty$ and there is no solution $\hat{x}$ of (1.1) on $I \cup \{\omega_+\}$ such that $\hat{x}|_I = x$. Similarly, a solution $x : I \to \mathbb{R}$ of (1.1) is said *left-nonextendible* if either $\omega_- = -\infty$, or $\omega_- > -\infty$ and there is no solution $\hat{x}$ of (1.1) on $I \cup \{\omega_-\}$ such that $\hat{x}|_I = x$. A solution $x :]\omega_-, \omega_+[\to \mathbb{R}$ of (1.1) is said *nonextendible* if it is both right-nonextendible and left-nonextendible.

We now introduce a notion of possibly discontinuous lower and upper solutions of (1.1), which have been extensively used in [38,52,86,28,112].

NOTATION 1.3. For a function $x : [t_1, t_2] \to \mathbb{R}$, we write $x|_{]t_1,t_2[} \in W^{1,1}(t_1, t_2)$ if there exists $\widetilde{x} \in W^{1,1}(t_1, t_2) \cap C^0([t_1, t_2])$ such that $\widetilde{x} = x$ on $]t_1, t_2[$.

DEFINITION 1.4.

- A *regular lower solution of* (1.1) *on* $[t_1, t_2]$, with $t_1, t_2 \in \mathbb{R}$ and $t_1 < t_2$, is a function $\alpha : [t_1, t_2] \to \mathbb{R}$, such that $\alpha|_{]t_1,t_2[} \in W^{1,1}(t_1, t_2)$,

$$\alpha'(t) \leqslant f\big(t, \alpha(t)\big) \quad \text{a.e. on } [t_1, t_2],$$

$$\lim_{t \to t_1^+} \alpha(t) \leqslant \alpha(t_1), \qquad \alpha(t_2) \leqslant \lim_{t \to t_2^-} \alpha(t).$$

- A *lower solution of* (1.1) *on* $[t_1, t_2]$ is a function $\alpha : [t_1, t_2] \to \mathbb{R}$ for which there are points $t_1 = \tau_0 < \tau_1 < \cdots < \tau_N = t_2$ such that, for $i = 0, \ldots, N-1$, $\alpha|_{[\tau_i, \tau_{i+1}]}$ is a regular lower solution on $[\tau_i, \tau_{i+1}]$.
- A *lower solution* (respectively a *regular lower solution*) *of* (1.1) *on* J, where J is a noncompact interval having endpoints t_1, t_2 with $-\infty \leqslant t_1 < t_2 \leqslant +\infty$, is a function α such that, for any compact interval $K \subset J$, $\alpha|_K$ is a lower solution (respectively a regular lower solution) of (1.1) on K.
- A *regular upper solution of* (1.1) *on* $[t_1, t_2]$, is a function $\beta : [t_1, t_2] \to \mathbb{R}$, such that $\beta|_{]t_1,t_2[} \in W^{1,1}(t_1, t_2)$,

$$\beta'(t) \geqslant f\big(t, \beta(t)\big) \quad \text{a.e. on } [t_1, t_2],$$

$$\lim_{t \to t_1^+} \beta(t) \geqslant \beta(t_1), \qquad \beta(t_2) \geqslant \lim_{t \to t_2^-} \beta(t).$$

- An *upper solution of* (1.1) *on* $[t_1, t_2]$ is a function $\beta : [t_1, t_2] \to \mathbb{R}$ for which there are points $t_1 = \sigma_0 < \sigma_1 < \cdots < \sigma_N = t_2$ such that, for $i = 0, \ldots, N-1$, $\beta|_{[\sigma_i, \sigma_{i+1}]}$ is a regular upper solution on $[\sigma_i, \sigma_{i+1}]$.
- An *upper solution* (respectively a *regular upper solution*) *of* (1.1) *on* J, where J is a noncompact interval having endpoints t_1, t_2 with $-\infty \leqslant t_1 < t_2 \leqslant +\infty$, is a function β such that, for any compact interval $K \subset J$, $\beta|_K$ is an upper solution (respectively a regular upper solution) of (1.1) on K.

REMARK 1.2. Notice that a regular lower solution α is (absolutely) continuous on $]t_1, t_2[$, but it may be discontinuous at the endpoints of the interval $[t_1, t_2]$. A similar observation holds for a regular upper solution.

Orderings

DEFINITION 1.5. Given functions $x, y : I \to \mathbb{R}$, with $I \subseteq \mathbb{R}$ an interval, we write
- $x \leqslant y$ if $x(t) \leqslant y(t)$ on I;
- $x < y$ if $x \leqslant y$ and $x \neq y$;
- $x \ll y$ if $\inf(y - x)|_K > 0$ for any compact interval $K \subseteq I$.

DEFINITION 1.6. Given functions $x, y : I \to \mathbb{R}$, with $I \subseteq \mathbb{R}$ an interval and $x < y$, we define the *order intervals*

$$\begin{aligned} &[x, y] = \{z : I \to \mathbb{R} \mid x \leqslant z \leqslant y\}, \\ &[x, +\infty[= \{z : I \to \mathbb{R} \mid x \leqslant z\}, \\ &]-\infty, y] = \{z : I \to \mathbb{R} \mid z \leqslant y\}. \end{aligned}$$

DEFINITION 1.7. Let $\mathcal{S}$ be a given set of solutions of (1.1).
- We say that a solution z of (1.1), with $z \in \mathcal{S}$, is a *maximal solution of* (1.1) *in* $\mathcal{S}$ (respectively a *minimal solution of* (1.1) *in* $\mathcal{S}$) if there is no solution x of (1.1), with $x \in \mathcal{S}$, such that $x > z$ (respectively $x < z$).
- We say that a solution z of (1.1), with $z \in \mathcal{S}$, is the *maximum solution of* (1.1) *in* $\mathcal{S}$ (respectively the *minimum solution of* (1.1) *in* $\mathcal{S}$) if every solution x of (1.1), with $x \in \mathcal{S}$, is such that $x \leqslant z$ (respectively $x \geqslant z$).

1.3. *The initial value problem*

In this section we collect some basic facts concerning the solvability of the Cauchy problem (1.2), when a pair of possibly discontinuous lower and upper solutions is given and no special ordering between them is assumed. Existence and localization of solutions, as well as the structure of the solution set, are discussed in this setting.

REMARK 1.3. Since the study of a terminal value problem may be reduced to the study of an initial value problem by reversing time, we shall mainly concentrate on the latter problem. Occasionally we shall need to refer to a terminal value problem; in that case we shall freely use definitions, notations and results about it without explicit references.

Solutions and lower and upper solutions

DEFINITION 1.8. A *solution of the initial value problem* (1.2) on I, with $I \subseteq \mathbb{R}$ an interval containing a right neighbourhood of t_0, is a solution x of (1.1) on I such that $x(t_0) = x_0$.

DEFINITION 1.9.

- A *lower solution* (respectively a *regular lower solution*) of (1.2) on I, with $I \subseteq \mathbb{R}$ an interval containing a right neighbourhood of t_0, is a function $\alpha : I \to \mathbb{R}$, which is a lower solution (respectively a regular lower solution) of (1.1) on I and satisfies $\alpha(t_0) \leqslant x_0$.
- An *upper solution* (respectively a *regular upper solution*) of (1.2) on I, with $I \subseteq \mathbb{R}$ an interval containing a right neighbourhood of t_0, is a function $\beta : I \to \mathbb{R}$, which is an upper solution (respectively a regular upper solution) of (1.1) on I and satisfies $\beta(t_0) \geqslant x_0$.

The following simple observation concerning pairs of unordered lower and upper solutions will be used in the sequel.

PROPOSITION 1.1. *Let α be a lower solution and β be an upper solution of* (1.2) *on* $[t_0, t_1]$ *with $\alpha \nleqslant \beta$. Then there exists $\hat{t} \in [t_0, t_1]$ such that $\alpha(\hat{t}) = \beta(\hat{t})$.*

PROOF. Let us set $\gamma = \beta - \alpha$. According to Definition 1.9, γ satisfies the following condition: there are points $t_0 = \rho_0 < \rho_1 < \cdots < \rho_K = t_1$ such that

- for $i = 0, \ldots, K-1$, $\gamma|_{]\rho_i, \rho_{i+1}[} \in W^{1,1}(\rho_i, \rho_{i+1})$,
- for $i = 1, \ldots, K-1$, $\lim_{t \to \rho_i^-} \gamma(t) \leqslant \gamma(\rho_i) \leqslant \lim_{t \to \rho_i^+} \gamma(t)$,
- $\lim_{t \to t_0^+} \gamma(t) \geqslant \gamma(t_0) \geqslant 0$ and $\gamma(t_1) \geqslant \lim_{t \to t_1^-} \gamma(t)$.

We may assume $\gamma(t_0) > 0$. Since $\alpha \nleqslant \beta$, there is a point $\xi \in]t_0, t_1]$ such that $\gamma(\xi) < 0$. Setting $\hat{t} = \sup\{t \in]t_0, \xi[\mid \gamma(s) > 0 \text{ on } [t_0, t]\}$, the properties of γ imply that $\gamma(\hat{t}) = 0$. □

Existence of solutions and the Hukuhara–Kneser property
We start with a basic existence and localization result for solutions of (1.1).

LEMMA 1.2. *Assume* (C). *Let $\alpha, \beta \in W^{1,1}(t_0, t_1)$ satisfy*

$$\alpha'(t) \leqslant f\big(t, \alpha(t)\big) \quad \textit{and} \quad \beta'(t) \geqslant f\big(t, \beta(t)\big) \quad \textit{a.e. on } [t_0, t_1]. \tag{1.4}$$

- *If $\alpha(t_0) \leqslant \beta(t_0)$, then for every $x_1 \in [\alpha(t_0), \beta(t_0)]$ there exists a solution $x : [t_0, t_1] \to \mathbb{R}$ of the initial value problem*

$$x' = f(t, x), \quad x(t_0) = x_1, \tag{1.5}$$

satisfying

$$\min\{\alpha,\beta\} \leqslant x \leqslant \max\{\alpha,\beta\} \quad \textit{on } [t_0,t_1]. \tag{1.6}$$

- *If* $\alpha(t_1) \geqslant \beta(t_1)$, *then for every* $x_2 \in [\beta(t_1),\alpha(t_1)]$ *there exists a solution* $x:[t_0,t_1] \to \mathbb{R}$ *of the terminal value problem*

$$x' = f(t,x), \quad x(t_1) = x_2, \tag{1.7}$$

  satisfying (1.6).
- *If* $\alpha(t_0) \leqslant \beta(t_0)$ *and* $\alpha(t_1) \geqslant \beta(t_1)$, *then for every* $x_1 \in [\alpha(t_0),\beta(t_0)]$ *and* $x_2 \in [\beta(t_1),\alpha(t_1)]$ *there exists a solution* $x:[t_0,t_1] \to \mathbb{R}$ *of both* (1.5) *and* (1.7) *satisfying* (1.6).

PROOF. We first consider the case where α and β are ordered.

CLAIM 1. *Let* $\alpha,\beta \in W^{1,1}(t_0,t_1)$ *satisfy* (1.4). *Assume that* $\alpha \leqslant \beta$ *on* $[t_0,t_1]$. *Then for each* $x_1 \in [\alpha(t_0),\beta(t_0)]$ *there exists a solution* $x:[t_0,t_1] \to \mathbb{R}$ *of* (1.5) *with* $\alpha \leqslant x \leqslant \beta$ *on* $[t_0,t_1]$.

Set $\gamma(t,x) = \max\{\alpha(t),\min\{x,\beta(t)\}\}$, $\bar{f}(t,x) = f(t,\gamma(t,x))$, and consider the problem

$$x' = \bar{f}(t,x), \quad x(t_0) = x_1. \tag{1.8}$$

Let $S:C^0([t_0,t_1]) \to C^0([t_0,t_1])$ be the Volterra operator defined by $S(x)(t) = x_1 + \int_{t_0}^{t} \bar{f}(s,x(s))\,\mathrm{d}s$. The operator S is continuous and has a relatively compact range. Hence, the existence of a solution x of (1.8) defined on $[t_0,t_1]$ follows from Schauder Theorem. We claim that $\alpha \leqslant x \leqslant \beta$ on $[t_0,t_1]$. Indeed, assuming that there are points s_1, s_2, with $t_0 \leqslant s_1 < s_2 \leqslant t_1$, such that $x(s_1) = \alpha(s_1)$ and $x(s) < \alpha(s)$ on $]s_1,s_2]$, yields $x'(s) - \alpha'(s) \geqslant 0$ a.e. on $]s_1,s_2]$, which leads to a contradiction. Therefore we have $\alpha \leqslant x$. Similarly we obtain $x \leqslant \beta$. Consequently x is a solution of (1.5) as well and the claim is proved.

CLAIM 2. *Let* $\alpha,\beta \in W^{1,1}(t_0,t_1)$ *satisfy* (1.4). *Assume that* $\alpha \geqslant \beta$ *on* $[t_0,t_1]$. *Then for each* $x_2 \in [\beta(t_1),\alpha(t_1)]$ *there exists a solution* $x:[t_0,t_1] \to \mathbb{R}$ *of* (1.7) *satisfying* $\alpha \geqslant x \geqslant \beta$ *on* $[t_0,t_1]$.

Let us consider the problem obtained from (1.7) by reversing time; namely, set $\hat{f}(t,x) = -f(t_0+t_1-t,x)$, $\hat{\alpha}(t) = \beta(t_0+t_1-t)$, $\hat{\beta}(t) = \alpha(t_0+t_1-t)$ and observe that $\hat{\alpha}'(t) \leqslant \hat{f}(t,\hat{\alpha}(t))$, $\hat{\beta}'(t) \geqslant \hat{f}(t,\hat{\beta}(t))$, a.e. on $[t_0,t_1]$, and that $\hat{\alpha}(t_0) \leqslant \hat{\beta}(t_0)$. By Claim 1 there exists a solution $\hat{x}:[t_0,t_1] \to \mathbb{R}$ of

$$x' = \hat{f}(t,x), \quad x(t_0) = x_2,$$

satisfying $\hat{\alpha} \leqslant \hat{x} \leqslant \hat{\beta}$ on $[t_0,t_1]$. The function $x(t) = \hat{x}(t_0+t_1-t)$ is then a solution of (1.7) satisfying $\alpha \geqslant x \geqslant \beta$ on $[t_0,t_1]$.

We now prove the three statements of this lemma.

Case 1: $\alpha(t_0) \leqslant \beta(t_0)$. Pick any $x_1 \in [\alpha(t_0), \beta(t_0)]$. Set $A = \{t \in [t_0, t_1] \mid \alpha(t) \leqslant \beta(t)\}$ and $B = [t_0, t_1] \setminus A$. We can write A as union of countably many disjoint closed intervals (possibly reduced to points) $[a_i, b_i]$, with $a_i \leqslant b_i$ and $a_0 = t_0$, and B as union of countably many disjoint open intervals $]c_j, d_j[$, with $c_j < d_j$. If $a_0 < b_0$, by Claim 1 we can find a solution x_0 of

$$x' = f(t, x), \quad x(t_0) = x_1,$$

satisfying $\alpha(t) \leqslant x_0(t) \leqslant \beta(t)$ on $[t_0, b_0]$ and, for every $i \geqslant 1$ such that $a_i < b_i$, a solution $x_i : [a_i, b_i] \to \mathbb{R}$ of

$$x' = f(t, x), \quad x(a_i) = \alpha(a_i),$$

satisfying $\alpha(t) \leqslant x_i(t) \leqslant \beta(t)$ on $[a_i, b_i]$. Notice that $x_i(b_i) = \alpha(b_i) = \beta(b_i)$ whenever $b_i \neq t_1$. For every j, by Claim 2 we can find a solution $y_j : [c_j, d_j] \to \mathbb{R}$ of

$$x' = f(t, x), \quad x(d_j) = \beta(d_j),$$

satisfying $\beta(t) \leqslant y_j(t) \leqslant \alpha(t)$ on $[c_j, d_j]$. Let us define $x : [t_0, t_1] \to \mathbb{R}$ by $x(t) = x_i(t)$ on $[a_i, b_i]$ and $x(t) = y_j(t)$ on $]c_j, d_j[$. Notice that $x(t_0) = x_1$, $x'(t) = f(t, x)$ a.e. on $[t_0, t_1]$ and (1.6) is satisfied. We only need to verify that x is absolutely continuous. Since x is bounded, by the L^1-Carathéodory conditions, there exists $\gamma \in L^1(t_0, t_1)$ such that $|f(t, x(t))| \leqslant \gamma(t)$ for all $t \in [t_0, t_1]$. Fix $\varepsilon > 0$ and pick points $r_k < s_k$ in $[t_0, t_1]$ with $k = 1, \dots, n$. Then $\sum_{k=1}^{n} |x(s_k) - x(r_k)|$ may be written as a series with terms of the form $|x_i(p_{k_i}) - x_i(q_{k_i})| \leqslant \int_{q_{k_i}}^{p_{k_i}} \gamma(s)\,\mathrm{d}s$ or $|y_j(p_{k_j}) - y_j(q_{k_j})| \leqslant \int_{q_{k_j}}^{p_{k_j}} \gamma(s)\,\mathrm{d}s$, whose sum is smaller than ε whenever $\sum_{k=1}^{n} |s_k - r_k|$ is sufficiently small.

Case 2: $\alpha(t_1) \geqslant \beta(t_1)$. We can argue as in Claim 2 applying our previous conclusion to a reversed time problem.

Case 3: $\alpha(t_0) \leqslant \beta(t_0)$ and $\alpha(t_1) \geqslant \beta(t_1)$. If either $\alpha(t_0) = \beta(t_0)$ or $\alpha(t_1) = \beta(t_1)$ the claim immediately follows from the previous cases. Otherwise, by Proposition 1.1 there exists a point $s_0 \in]t_0, t_1[$ such that $\alpha(s_0) = \beta(s_0)$. The assertion then follows by applying our preceding conclusions to problem (1.5) on $[t_0, s_0]$ and to problem (1.7) on $[s_0, t_1]$. □

We use Lemma 1.2 to recover an existence and localization result established in [28] under a slightly more restrictive notion of lower and upper solutions. We add here some information on the topological structure of the solution set, namely we prove the Hukuhara–Kneser property. In order to show that it is (arcwise) connected, we exploit the following property of compact subsets of $C^0([t_0, t_1])$ which are dense-in-itself with respect to the order.

DEFINITION 1.10. A subset $\mathcal{S}$ of $C^0([t_0, t_1])$ is said *dense-in-itself with respect to the order* if for any $u_1, u_2 \in \mathcal{S}$, with $u_1 < u_2$, there exists $u_3 \in \mathcal{S}$ with $u_1 < u_3 < u_2$.

LEMMA 1.3. *Let $\mathcal{S} \subseteq C^0([t_0, t_1])$ be a compact set which is dense-in-itself with respect to the order. Let $\mathcal{T} \subseteq \mathcal{S}$ be a maximal nondegenerate totally ordered subset of $\mathcal{S}$. Then $\mathcal{T}$ is homeomorphic to a nondegenerate compact interval of $\mathbb{R}$.*

PROOF. We start by verifying that $\mathcal{T}$ is closed in $\mathcal{S}$. Let $(z_n)_n$ be a sequence in $\mathcal{T}$ converging to some function $z \in \mathcal{S}$. Let us show that $z \in \mathcal{T}$, that is, for each $u \in \mathcal{T}$, either $u \leqslant z$ or $u \geqslant z$. Assume by contradiction that there exists $u \in \mathcal{T}$ such that $u \nleqslant z$ and $u \ngeqslant z$, i.e. $\min\{\|(u-z)^+\|_\infty, \|(u-z)^-\|_\infty\} > 0$. Take n such that $\|z_n - z\|_\infty < \min\{\|(u-z)^+\|_\infty, \|(u-z)^-\|_\infty\}$ and suppose, for instance, that $z_n \geqslant u$. We have $(z_n - z)^+ \geqslant (u-z)^+$ and hence $\|(u-z)^+\|_\infty \leqslant \|(z_n - z)^+\|_\infty \leqslant \|z_n - z\|_\infty < \|(u-z)^+\|_\infty$, which is a contradiction. Therefore, we conclude that $z \in \mathcal{T}$.

Moreover, as $\mathcal{T}$ is a maximal totally ordered subset of $\mathcal{S}$, $\mathcal{T}$ is dense-in-itself with respect to the order. Let $\varphi : C^0([t_0, t_1]) \to \mathbb{R}$ be a continuous linear functional such that $\varphi(u) > 0$ for every $u > 0$ (e.g., $\varphi(u) = \int_{t_0}^{t_1} u$). Since $\mathcal{T}$ is compact and $\varphi|_{\mathcal{T}}$ is one-to-one, $\varphi|_{\mathcal{T}}$ is a homeomorphism between $\mathcal{T}$ and $\varphi(\mathcal{T}) \subseteq \mathbb{R}$. Notice that $\varphi(\mathcal{T})$ is also dense-in-itself with respect to the ordering of $\mathbb{R}$ and hence it is a nondegenerate compact interval. □

THEOREM 1.4. *Assume* (C). *Let α be a lower solution and β be an upper solution of* (1.2) *on* $[t_0, t_1]$. *Then there exist the minimum solution v and the maximum solution w in* $[\min\{\alpha, \beta\}, \max\{\alpha, \beta\}]$ *of* (1.2) *on* $[t_0, t_1]$. *Further, the set*

$$\mathcal{K} = \left\{x : [t_0, t_1] \to \mathbb{R} \mid x \text{ is a solution of } (1.2) \text{ with } \min\{\alpha, \beta\} \leqslant x \leqslant \max\{\alpha, \beta\}\right\}$$

is a continuum, i.e. a compact and connected set, in $C^0([t_0, t_1])$.

PROOF. In this proof we use the following notations: if I is an interval, with endpoints a and b, and $u : I \to \mathbb{R}$, then we set $u(a^+) = \lim_{t\to a^+} u(t)$ and $u(b^-) = \lim_{t \to b^-} u(t)$, whenever the limits exist. The proof is divided into three steps.

Step 1. *Existence of a solution.* Let $\tau_0, \tau_1, \ldots, \tau_N$ and $\sigma_0, \sigma_1, \ldots, \sigma_M$ be the points of $[t_0, t_1]$ defining α and β as in Definition 1.9 and relabel them as $\rho_0 < \rho_1 < \cdots < \rho_P$. For each $n = 1, \ldots, P$ denote by α_n, β_n the continuous extensions on $[\rho_{n-1}, \rho_n]$ of $\alpha|_{]\rho_{n-1}, \rho_n[}$ and $\beta|_{]\rho_{n-1}, \rho_n[}$, respectively. We will prove the thesis by recursion on P.

- *There exists a solution y_1 of* (1.2) *such that* $\min\{\alpha, \beta\} \leqslant y_1 \leqslant \max\{\alpha, \beta\}$ *on* $[t_0, \rho_1]$. *Further, if* $\alpha(\rho_1^-) \geqslant \beta(\rho_1^-)$, *then for any x_1 between* $\min\{\alpha(\rho_1^-), \beta(\rho_1)\}$ *and* $\max\{\alpha(\rho_1), \beta(\rho_1^-)\}$, *the solution y_1 can be chosen so that* $y_1(\rho_1) = x_1$.

As $\alpha_1(t_0) = \alpha(t_0^+) \leqslant \alpha(t_0) \leqslant x_0 \leqslant \beta(t_0) \leqslant \beta(t_0^+) = \beta_1(t_0)$, the claim follows by Lemma 1.2.

- *Let* $n \leqslant P - 1$. *Assume there exists a solution y_n of* (1.2) *such that* $\min\{\alpha, \beta\} \leqslant y_n \leqslant \max\{\alpha, \beta\}$ *on* $[t_0, \rho_n]$ *and, in case* $\alpha(\rho_n^-) \geqslant \beta(\rho_n^-)$, *for all x_n between* $\min\{\alpha(\rho_n^-), \beta(\rho_n)\}$ *and* $\max\{\alpha(\rho_n), \beta(\rho_n^-)\}$ *the solution y_n can be chosen so that* $y_n(\rho_n) = x_n$. *Then there exists a solution y_{n+1} of* (1.2) *such that* $\min\{\alpha, \beta\} \leqslant y_{n+1} \leqslant \max\{\alpha, \beta\}$ *on* $[t_0, \rho_{n+1}]$ *and, in case* $\alpha(\rho_{n+1}^-) \geqslant \beta(\rho_{n+1}^-)$, *for all x_{n+1} between* $\min\{\alpha(\rho_{n+1}^-), \beta(\rho_{n+1})\}$ *and* $\max\{\alpha(\rho_{n+1}), \beta(\rho_{n+1}^-)\}$ *the solution y_{n+1} can be chosen so that* $y_{n+1}(\rho_{n+1}) = x_{n+1}$.

To prove this we need to distinguish several cases.

(i) Assume $\alpha(\rho_n^-) \leqslant \beta(\rho_n^-)$. Hence $\alpha(\rho_n) \leqslant \beta(\rho_n)$. Let y_n be a solution as in the assumption. As $\alpha_{n+1}(\rho_n) \leqslant y_n(\rho_n) \leqslant \beta_{n+1}(\rho_n)$, by Lemma 1.2 there exists a solution z of (1.1) such that $z(\rho_n) = y_n(\rho_n)$, $\min\{\alpha_{n+1}, \beta_{n+1}\} \leqslant z \leqslant \max\{\alpha_{n+1}, \beta_{n+1}\}$ on $[\rho_n, \rho_{n+1}]$ and, in case $\alpha_{n+1}(\rho_{n+1}) \geqslant \beta_{n+1}(\rho_{n+1})$, for all $x_{n+1} \in [\beta_{n+1}(\rho_{n+1}), \alpha_{n+1}(\rho_{n+1})]$ such a solution can be chosen so that $z(\rho_{n+1}) = x_{n+1}$. Since in this case the interval $[\beta_{n+1}(\rho_{n+1}), \alpha_{n+1}(\rho_{n+1})]$ is contained in the interval with endpoints $\min\{\alpha(\rho_{n+1}^-), \beta(\rho_{n+1})\}$ and $\max\{\alpha(\rho_{n+1}), \beta(\rho_{n+1}^-)\}$, the function y_{n+1} defined by $y_{n+1}(t) = y_n(t)$ on $[t_0, \rho_n]$ and $y_{n+1}(t) = z(t)$ on $[\rho_n, \rho_{n+1}]$ is as required.

(ii) Assume $\alpha(\rho_n^-) > \beta(\rho_n^-)$ and $\alpha(\rho_n) \leqslant \beta(\rho_n)$. Then $\max\{\alpha(\rho_n), \beta(\rho_n^-)\} \leqslant \min\{\alpha(\rho_n^-), \beta(\rho_n)\}$. Let $x_n \in [\max\{\alpha(\rho_n), \beta(\rho_n^-)\}, \min\{\alpha(\rho_n^-), \beta(\rho_n)\}]$. By assumption there exists a solution y_n of (1.2) such that $\min\{\alpha, \beta\} \leqslant y_n \leqslant \max\{\alpha, \beta\}$ on $[t_0, \rho_n]$ and $y_n(\rho_n) = x_n$. As $\alpha_{n+1}(\rho_n) \leqslant y_n(\rho_n) \leqslant \beta_{n+1}(\rho_n)$, arguing as in (i) we get the existence of the solution y_{n+1} with all the required properties.

(iii) Assume $\alpha(\rho_n) > \beta(\rho_n)$ (hence $\alpha(\rho_n^-) > \beta(\rho_n^-)$) and $\alpha(\rho_n^+) \leqslant \beta(\rho_n^+)$. Let $x_n \in [\alpha(\rho_n^+), \beta(\rho_n^+)] \cap [\beta(\rho_n), \alpha(\rho_n)]$ and argue as in (ii).

(iv) Assume $\alpha(\rho_n^+) > \beta(\rho_n^+)$ (hence $\alpha(\rho_n) > \beta(\rho_n)$ and $\alpha(\rho_n^-) > \beta(\rho_n^-)$) and $\alpha(\rho_{n+1}^-) > \beta(\rho_{n+1}^-)$. For any x_{n+1} between $\min\{\alpha(\rho_{n+1}^-), \beta(\rho_{n+1})\}$ and $\max\{\alpha(\rho_{n+1}), \beta(\rho_{n+1}^-)\}$ we have $\alpha_{n+1}(\rho_{n+1}) \geqslant x_{n+1} \geqslant \beta_{n+1}(\rho_{n+1})$ and hence, by Lemma 1.2, there exists a solution z of (1.1) such that $z(\rho_{n+1}) = x_{n+1}$ and $\min\{\alpha_{n+1}, \beta_{n+1}\} \leqslant z \leqslant \max\{\alpha_{n+1}, \beta_{n+1}\}$ on $[\rho_n, \rho_{n+1}]$. As $\beta(\rho_n) \leqslant \beta(\rho_n^+) \leqslant z(\rho_n) \leqslant \alpha(\rho_n^+) \leqslant \alpha(\rho_n)$, by assumption there exists a solution y_n of (1.2) such that $\min\{\alpha, \beta\} \leqslant y_n \leqslant \max\{\alpha, \beta\}$ on $[t_0, \rho_n]$ and $y_n(\rho_n) = z(\rho_n)$. The function y_{n+1} defined by $y_{n+1}(t) = y_n(t)$ on $[t_0, \rho_n]$ and $y_{n+1}(t) = z(t)$ on $[\rho_n, \rho_{n+1}]$ is as required.

(v) Assume $\alpha(\rho_n^+) > \beta(\rho_n^+)$ (hence $\alpha(\rho_n) > \beta(\rho_n)$ and $\alpha(\rho_n^-) > \beta(\rho_n^-)$) and $\alpha(\rho_{n+1}^-) \leqslant \beta(\rho_{n+1}^-)$. By continuity there is a point $\hat{t} \in]\rho_n, \rho_{n+1}[$ such that $\alpha(\hat{t}) = \beta(\hat{t})$. Arguing as in (iv), by Lemma 1.2 for any x_{n+1} between $\min\{\alpha(\rho_{n+1}^-), \beta(\rho_{n+1})\}$ and $\max\{\alpha(\rho_{n+1}), \beta(\rho_{n+1}^-)\}$ there exists a solution z_2 of (1.1) such that $z_2(\hat{t}) = \alpha(\hat{t})$, $z_2(\rho_{n+1}) = x_{n+1}$ and $\min\{\alpha_{n+1}, \beta_{n+1}\} \leqslant z_2 \leqslant \max\{\alpha_{n+1}, \beta_{n+1}\}$ on $[\hat{t}, \rho_{n+1}]$. Further there exists a solution z_1 of (1.1) such that $z_1(\hat{t}) = \alpha(\hat{t})$ and $\min\{\alpha_{n+1}, \beta_{n+1}\} \leqslant z_1 \leqslant \max\{\alpha_{n+1}, \beta_{n+1}\}$ on $[\rho_n, \hat{t}]$. As $\beta(\rho_n) \leqslant \beta(\rho_n^+) \leqslant z_1(\rho_n) \leqslant \alpha(\rho_n^+) \leqslant \alpha(\rho_n)$, by assumption there exists a solution y_n of (1.2) such that $\min\{\alpha, \beta\} \leqslant y_n \leqslant \max\{\alpha, \beta\}$ on $[t_0, \rho_n]$ and $y_n(\rho_n) = z_1(\rho_n)$. The function y_{n+1} defined by $y_{n+1}(t) = y_n(t)$ on $[t_0, \rho_n]$, $y_{n+1}(t) = z_1(t)$ on $[\rho_n, \hat{t}]$, $y_{n+1}(t) = z_2(t)$ on $[\hat{t}, \rho_{n+1}]$ is as required.

Step 2. Existence of extremal solutions. We have just seen that $\mathcal{K}$ is nonempty. Let us show that $\mathcal{K}$ has a minimum and a maximum. Since the Volterra operator $S : C^0([t_0, t_1]) \to C^0([t_0, t_1])$ associated with (1.2) is completely continuous and the set of its fixed points lying between $\min\{\alpha, \beta\}$ and $\max\{\alpha, \beta\}$ is precisely $\mathcal{K}$, we have that $\mathcal{K}$ is a nonempty compact set. For each $x \in \mathcal{K}$ define the closed set $\mathcal{C}_x = \{z \in \mathcal{K} \mid z \leqslant x\}$. The family $\{\mathcal{C}_x \mid x \in \mathcal{K}\}$ has the finite intersection property since, if $x_1, x_2 \in \mathcal{K}$, then $\min\{x_1, x_2\} \in \mathcal{K}$. By the compactness of $\mathcal{K}$ there exists $v \in \bigcap_{x \in \mathcal{K}} \mathcal{C}_x$; clearly, v is the minimum solution we are looking for. The maximum solution w can be found in a similar way.

Step 3. $\mathcal{K}$ is a continuum. We have only to show that $\mathcal{K}$ is connected. Let us prove that $\mathcal{K}$ is dense-in-itself with respect to the order. Take $x_1, x_2 \in \mathcal{K}$ with $x_1 < x_2$. Let $s_0 \in]t_0, t_1[$ be such that $x_1(s_0) < x_2(s_0)$ and pick a real number $\hat{x}_0$ with $x_1(s_0) < \hat{x}_0 < x_2(s_0)$. By Lemma 1.2 there exists a solution $x_3 : [t_0, t_1] \to \mathbb{R}$ of (1.1), satisfying $x_3(t_0) = x_0$ and $x_3(s_0) = \hat{x}_0$, such that $x_1 \leqslant x_3 \leqslant x_2$; hence $x_3 \in \mathcal{K}$ and $x_1 < x_3 < x_2$. Let us show that $\mathcal{K}$ is arcwise connected. For any $x_1, x_2 \in \mathcal{K}$, with $x_1 \neq x_2$, let $\mathcal{T}_1$ be a maximal totally ordered subset of $\mathcal{K}$ containing x_1 and $\min\{x_1, x_2\}$ and let $\mathcal{T}_2$ be a maximal totally ordered subset of

$\mathcal{K}$ containing x_2 and $\min\{x_1, x_2\}$. By Lemma 1.3, $\mathcal{T}_1$ and $\mathcal{T}_2$ are homeomorphic to compact real intervals. Since $\min\{x_1, x_2\} \in \mathcal{T}_1 \cap \mathcal{T}_2$, we find an arc connecting x_1 to x_2. □

In the sequel we shall also use the following partial extension of Theorem 1.4 to noncompact intervals. Related results can be found in [90].

COROLLARY 1.5. *Assume* (C). *Let α be a lower solution and β be an upper solution of* (1.2) *on* $[t_0, \tau[$, *with* $t_0 < \tau \leqslant +\infty$, *and assume that* $\alpha \leqslant \beta$. *Then there exists the minimum solution v and the maximum solution w in* $[\alpha, \beta]$ *of* (1.2) *on* $[t_0, \tau[$. *Further, the set*

$$\mathcal{K} = \big\{x : [t_0, \tau[\to \mathbb{R} \mid x \textit{ is a solution of } (1.2) \textit{ with } \alpha \leqslant x \leqslant \beta\big\}$$

is a continuum in $C^0([t_0, \tau[)$, *endowed with the topology of uniform convergence on compact intervals.*

PROOF. Let $(\tau_n)_n$, with $\tau_0 = t_0$, be a strictly increasing sequence converging to τ.

Step 1. *Existence of extremal solutions.* In order to prove the existence of the minimum solution v in $[\alpha, \beta]$ of (1.2) on $[t_0, \tau[$, we apply recursively Theorem 1.4 on each interval $[t_0, \tau_n]$, with $n \geqslant 1$ Let us denote by v_n the minimum solution v in $[\alpha, \beta]$ of (1.2) on $[t_0, \tau_n]$. By the minimality of v_n, we have $v_{n+1}|_{[t_0,\tau_n]} \geqslant v_n$. On the other hand, as $\alpha|_{[\tau_n,\tau_{n+1}]}$ and $v_{n+1}|_{[\tau_n,\tau_{n+1}]}$ are, respectively, a lower and an upper solution of the initial value problem $x' = f(t, x)$, $x(\tau_n) = v_n(\tau_n)$, we can continue v_n to a solution $\hat{v}_{n+1}$ of (1.2) on $[t_0, \tau_{n+1}]$ satisfying $\alpha \leqslant \hat{v}_{n+1} \leqslant v_{n+1}$. By the minimality of v_{n+1}, we conclude that $\hat{v}_{n+1} = v_{n+1}$ and hence $v_{n+1}|_{[t_0,\tau_n]} = v_n$. Then we define $v : [t_0, \tau[\to \mathbb{R}$ by setting $v(t) = v_n(t)$ on $[t_0, \tau_n]$. We have that v is the minimum solution in $[\alpha, \beta]$ of (1.2) on $[t_0, \tau[$, because, if x were a solution of (1.2) on $[t_0, \tau[$ with $x \geqslant \alpha$ and $x \ngeqslant v$, then it should follow $x|_{[t_0,\tau_n]} \ngeqslant v_n$ for some n, thus contradicting the minimality of v_n. Similarly, we prove the existence of the maximum solution w in $[\alpha, \beta]$ of (1.2) on $[t_0, \tau[$.

Step 2. *$\mathcal{K}$ is a continuum.* For each $x \in \mathcal{K}$ and $n \geqslant 1$, set $x_n = x|_{[t_0,\tau_n]}$. We denote by $\mathcal{K}_n$ the set of all solutions $x : [t_0, \tau_n] \to \mathbb{R}$ of (1.2) such that $\alpha \leqslant x \leqslant \beta$ on $[t_0, \tau_n]$. By Theorem 1.4, $\mathcal{K}_n$ is a continuum in $C^0([t_0, \tau_n])$. For every $m < n$, let also $\pi^n_m : \mathcal{K}_n \to \mathcal{K}_m$ be the restriction map on $[t_0, \tau_m]$, i.e. $\pi^n_m(x) = x|_{[t_0,\tau_m]}$ for all $x \in \mathcal{K}_n$. Let us define now a function $\chi : \mathcal{K} \to \prod_{n=1}^{+\infty} \mathcal{K}_n$, by setting $\chi(x) = (x_n)_n$. Observe that χ is a homeomorphism of $\mathcal{K}$ into $\prod_{n=1}^{+\infty} \mathcal{K}_n$, when $\prod_{n=1}^{+\infty} \mathcal{K}_n$ is endowed with the Tychonoff product topology, and its range $\chi(\mathcal{K})$ is the set of all sequences $(x_n)_n \in \prod_{n=1}^{+\infty} \mathcal{K}_n$ such that, for all $m < n$, $\pi^n_m(x_n) = x_m$, i.e. $\chi(\mathcal{K})$ is the inverse limit of the sequence $(\mathcal{K}_n)_n$ with bonding maps π^n_m (cf. [47]). As the inverse limit of a sequence of continua is a continuum [47, Theorem 6.1.20] we deduce that $\chi(\mathcal{K})$ is a continuum as well. Since $\mathcal{K}$ is homeomorphic to $\chi(\mathcal{K})$, the conclusion is achieved. □

1.4. *The periodic problem*

In this section we discuss existence and localization of solutions of the periodic problem (1.3), in the presence of a pair of possibly discontinuous and unordered lower and upper solutions. With the aim of obtaining a global portrait of solutions of Eq. (1.1), we also introduce the notion of T-monotonicity. This concept plays a central role in the qualitative study of solutions of (1.1), as it helps to get a thorough classification of their asymptotic behaviour. Therefore we develop some criteria for detecting T-monotonicity. However, it should be stressed that also the study of solutions that are not T-monotone has an interest, since their existence gives rise to T-periodic solutions. All these facts are then used to get an extension of the existence part of the classical Massera Convergence Theorem to the Carathéodory setting.

Solutions and lower and upper solutions

DEFINITION 1.11. A *solution of* (1.3) is a solution u of (1.1) on $\mathbb{R}$ which is T-periodic, i.e. $u(t+T) = u(t)$ on $\mathbb{R}$.

We introduce some notions of possibly discontinuous lower and upper solutions for the periodic problem (1.3).

DEFINITION 1.12.

- A *lower solution of* (1.3) is a T-periodic function $\alpha : \mathbb{R} \to \mathbb{R}$ which is a lower solution of (1.1) on $\mathbb{R}$.
- A *regular lower solution of* (1.3) is a lower solution α of (1.3) such that $\alpha|_{[0,T]}$ is a regular lower solution of (1.1) on $[0, T]$.
- An *upper solution of* (1.3) is a T-periodic function $\beta : \mathbb{R} \to \mathbb{R}$ which is an upper solution of (1.1) on $\mathbb{R}$.
- A *regular upper solution of* (1.3) is an upper solution β of (1.3) such that $\beta|_{[0,T]}$ is a regular upper solution of (1.1) on $[0, T]$.
- A lower solution of (1.3) (respectively an upper solution of (1.3)) is *proper* if it is not a solution of (1.3).
- A proper lower solution α of (1.3) is *strict* if every solution x of (1.3), with $x > \alpha$, is such that $x \gg \alpha$. Similarly, a proper upper solution of (1.3) is *strict* if every solution x of (1.3), with $x < \beta$, is such that $x \ll \beta$.

REMARK 1.4. We notice that even regular lower and upper solutions of (1.3) may be discontinuous at the endpoints of the interval $[0, T]$.

REMARK 1.5. Sometimes we speak of solutions of (1.3) with reference to functions defined on $[t_0, t_0 + T]$ for some $t_0 \in \mathbb{R}$. We also speak of lower and upper solutions of (1.3) with reference to functions defined on $[t_0, t_0 + T[$ for some $t_0 \in \mathbb{R}$. In these cases it is understood that their T-periodic extensions to $\mathbb{R}$ have to be considered.

In the sequel we shall need the following observation, whose proof is a slight modification of that of Proposition 1.1.

PROPOSITION 1.6. *Let α be a lower solution and β be an upper solution of* (1.3), *with $\alpha \not\leqslant \beta$ and $\alpha \not\geqslant \beta$. Then there exists $\hat{t} \in [0, T]$ such that $\alpha(\hat{t}) = \beta(\hat{t})$.*

T-monotonicity

The notion of T-monotonicity plays an important role in the qualitative study of solutions of (1.1). When uniqueness of solutions of (1.2) holds, then any solution is T-monotone and this, in turn, corresponds to the monotonicity of the Poincaré operator. Of course, in the Carathéodory setting this is not anymore true.

DEFINITION 1.13.

- A function $x : I \to \mathbb{R}$, where $I \subseteq \mathbb{R}$ is an interval, is said *T-increasing* (respectively, *T-decreasing*) if $x(t) \leqslant x(t+T)$ (respectively $x(t) \geqslant x(t+T)$) for each $t \in I$ such that $t + T \in I$. A function is said *T-monotone* if it is either T-increasing or T-decreasing.
- A function $x : I \to \mathbb{R}$, where $I \subseteq \mathbb{R}$ is an interval unbounded from above, is said *eventually T-increasing* (respectively, *eventually T-decreasing*) if there exists $t_0 \in I$ such that $x|_{]t_0,+\infty[}$ is T-increasing (respectively, T-decreasing).

REMARK 1.6. Let x be a solution of (1.1) on $[t_0, +\infty[$. If x is T-increasing then the sequence $(\alpha_n)_n$, defined by setting, for each $n \geqslant t_0/T$, $\alpha_n(t) = x(t+nT)$ on $[0, T[$ gives rise to an increasing sequence of regular lower solutions of (1.3). Similarly, any T-decreasing solution of (1.1) on $[t_0, +\infty[$, gives rise to a decreasing sequence $(\beta_n)_n$ of regular upper solutions of (1.3).

The Massera Convergence Theorem for T-monotone solutions

The following simple result may be considered as a first step towards an extension of the classical Massera Convergence Theorem for scalar ordinary differential equations [91] to the case where the right-hand side f of (1.1) is a Carathéodory function.

PROPOSITION 1.7. *Assume* (C). *Let $x :]t_0, +\infty[\to \mathbb{R}$ be a bounded, T-increasing* (*respectively T-decreasing*) *solution of* (1.1). *Then there exists a solution u of* (1.3) *such that $u \geqslant x$* (*respectively $u \leqslant x$*) *on* $]t_0, +\infty[$ *and*

$$\lim_{t\to+\infty} \bigl(x(t) - u(t)\bigr) = 0. \tag{1.9}$$

REMARK 1.7. Symmetrically, we have that, if $x :]-\infty, t_0[\to \mathbb{R}$ is a bounded, T-increasing (respectively T-decreasing) solution of (1.1), then there exists a solution u of (1.3) such that $u \leqslant x$ (respectively $u \geqslant x$) on $]-\infty, t_0[$ and

$$\lim_{t\to-\infty} \bigl(x(t) - u(t)\bigr) = 0.$$

PROOF. Assume, without loss of generality, that $t_0 = n_0 T$, for some $n_0 \in \mathbb{N}$, and suppose that x is T-increasing. Define a sequence $(x_n)_n$ of functions by setting, for every $n \geqslant n_0$ and every $t \in [0, T]$, $x_n(t) = x(t + nT)$. Then x_n is a regular lower solution of (1.3), satisfying

$$x_{n+1}(0) = x_n(T) \tag{1.10}$$

and $x_n \leqslant x_{n+1}$, on $[0, T]$. By assumption, the sequence $(x_n)_n$ is bounded in $C^0([0, T])$ and hence, by monotonicity, it converges pointwise on $[0, T]$ to a function u, which by (1.10) satisfies $u(0) = u(T)$. Moreover, the L^1-Carathéodory conditions imply that $(x_n)_n$ is equicontinuous. Therefore, by Arzelà–Ascoli theorem and monotonicity, $(x_n)_n$ converges uniformly to u. Finally, using the integral representation of solutions of (1.1) and the L^1-Carathéodory conditions again, we conclude that u is a solution and that the convergence takes place in $W^{1,1}(0, T)$.

Let us show now that $\lim_{t\to+\infty}(x(t) - u(t)) = 0$. Indeed, since $(x_n)_n$ converges uniformly to u, given $\varepsilon > 0$ there is $\bar{n}$ such that, for any $n \geqslant \bar{n}$, $|x_n(t) - u(t)| < \varepsilon$ for all $t \in [0, T]$. Hence, if we take $t \geqslant \bar{n}T$, with $t \in [nT, (n + 1)T[$ for some $n \geqslant \bar{n}$, we obtain, by the T-periodicity of u, $|x(t) - u(t)| = |x_n(t - nT) - u(t - nT)| < \varepsilon$. □

A Monotone Convergence Criterion

We now prove a technical result, which will often be used in the sequel. It describes the qualitative behaviour of solutions of (1.1), emanating from and lying above a lower solution of (1.3). Among these we single out a special solution $\widetilde{\alpha}$ which is T-increasing and hence, if bounded, does converge to a T-periodic solution. This statement is reminiscent of the Monotone Convergence Criterion in the theory of monotone maps (cf. [60, Section 5]) and essentially reduces to it when uniqueness of solutions of (1.2) holds.

PROPOSITION 1.8. *Assume* (C).

(i) *Let α be a lower solution of* (1.3) *and let $t_0 \in \mathbb{R}$. Then there exist $\omega \in\,]t_0, +\infty]$ and a T-increasing solution $\widetilde{\alpha} : [t_0, \omega[\to \mathbb{R}$ of* (1.2), *with $x_0 = \alpha(t_0)$, satisfying $\widetilde{\alpha} \geqslant \alpha$ on $[t_0, \omega[$. Further, every solution $x : [t_0, \tau[\to \mathbb{R}$ of* (1.1), *with $x \geqslant \alpha$, is such that $\tau \leqslant \omega$ and $x \geqslant \widetilde{\alpha}$ on $[t_0, \tau[$. Finally, we have that either every right-nonextendible solution $x : [t_0, \tau[\to \mathbb{R}$ of* (1.1), *with $x \geqslant \alpha$, is such that*

$$\limsup_{t\to\tau} x(t) = +\infty$$

and (1.3) *has no solution in $[\alpha, +\infty[$, or there exists the minimum solution v in $[\alpha, +\infty[$ of* (1.3); *in the latter case $\omega = +\infty$, $v \geqslant \widetilde{\alpha}$ and*

$$\lim_{t\to+\infty} \big(\widetilde{\alpha}(t) - v(t)\big) = 0.$$

(ii) *Let β be an upper solution of* (1.3) *and let $t_0 \in \mathbb{R}$. Then there exist $\omega \in\,]t_0, +\infty]$ and a T-decreasing solution $\widetilde{\beta} : [t_0, \omega[\to \mathbb{R}$ of* (1.2), *with $x_0 = \beta(t_0)$, satisfying $\widetilde{\beta} \leqslant \beta$ on $[t_0, \omega[$. Further, every solution $x : [t_0, \tau[\to \mathbb{R}$ of* (1.1), *with $x \leqslant \beta$, is such that $\tau \leqslant \omega$ and $x \leqslant \widetilde{\beta}$ on $[t_0, \tau[$. Finally, we have that either every right-nonextendible solution $x : [t_0, \tau[\to \mathbb{R}$ of* (1.1), *with $x \leqslant \beta$, is such that*

$$\liminf_{t\to\tau} x(t) = -\infty$$

and (1.3) *has no solution in* $]-\infty, \beta]$, *or there exists the maximum solution* w *in* $]-\infty, \beta]$ *of* (1.3); *in the latter case* $\omega = +\infty$, $w \leqslant \widetilde{\beta}$ *and*

$$\lim_{t \to +\infty} \bigl(\widetilde{\beta}(t) - w(t)\bigr) = 0.$$

REMARK 1.8. If $\omega < +\infty$, then $\lim_{t \to \omega} \widetilde{\alpha}(t) = +\infty$. Whereas, it may happen that, if $\omega = +\infty$, $\limsup_{t \to \omega} \widetilde{\alpha}(t) = +\infty$ and $\liminf_{t \to \omega} \widetilde{\alpha}(t) < +\infty$. A simple example is found by taking, in (1.1), $f(t,x) = x^2 \sin t$ if $|t| \leqslant \pi$, $f(t,x) = -x \sin t$ if $\pi < t < 2\pi$, and extending f by 3π-periodicity with respect to the t-variable. A similar remark holds for $\widetilde{\beta}$.

PROOF. We only prove statement (i), as the proof of (ii) is similar.

Let $\omega \in]t_0, +\infty]$ be the supremum of all $\tau > t_0$ such that there exists a solution $x : [t_0, \tau] \to \mathbb{R}$ of (1.2), with $x_0 = \alpha(t_0)$, satisfying $x \geqslant \alpha$ on $[t_0, \tau]$. The existence of such solutions x follows applying Theorem 1.4 to a modified problem. Take a strictly increasing sequence $(\tau_n)_n$ such that $\tau_n \to \omega$ and let $(x_n)_n$ be a corresponding sequence of solutions. Since x_1 is an upper solution and $\alpha|_{[t_0, \tau_1]}$ is a lower solution of (1.2), with $x_0 = \alpha(t_0)$, Theorem 1.4 yields the existence of the minimum solution v_1 in $[\alpha, x_1]$ of (1.2) on $[t_0, \tau_1]$. Actually, v_1 is the minimum solution in $[\alpha, +\infty[$ of (1.2), with $x_0 = \alpha(t_0)$, on $[t_0, \tau_1]$. Since $x_2|_{[\tau_1, \tau_2]}$ is an upper solution and $\alpha|_{[\tau_1, \tau_2]}$ is a lower solution of

$$x' = f(t,x), \quad x(\tau_1) = v_1(\tau_1), \tag{1.11}$$

on $[\tau_1, \tau_2]$, there is the minimum solution v_2 in $[\alpha, x_2]$ of (1.11) on $[\tau_1, \tau_2]$. Actually, v_2 is the minimum solution in $[\alpha, +\infty[$ of (1.11) on $[\tau_1, \tau_2]$. Proceeding in this way, we construct a sequence $(v_n)_n$ such that, for each n, v_n is the minimum solution in $[\alpha, +\infty[$ of

$$x' = f(t,x), \quad x(\tau_{n-1}) = v_{n-1}(\tau_{n-1}),$$

on $[\tau_{n-1}, \tau_n]$. Now, we define a function $\widetilde{\alpha} : [t_0, \omega[\to \mathbb{R}$ by setting

$$\widetilde{\alpha}(t) = v_n(t) \quad \text{if } t \in [\tau_{n-1}, \tau_n[.$$

It is clear that $\widetilde{\alpha}$ is a right-nonextendible solution of (1.2), with $x_0 = \alpha(t_0)$, satisfying $\widetilde{\alpha} \geqslant \alpha$ on $[t_0, \omega[$. Moreover, from the minimality of each v_n we deduce that every solution $x : [t_0, \tau[\to \mathbb{R}$ of (1.2), with $x_0 = \alpha(t_0)$, satisfying $x \geqslant \alpha$, is such that $\tau \leqslant \omega$ and $x \geqslant \widetilde{\alpha}$ on $[t_0, \tau[$. The same holds if $x_0 > \alpha(t_0)$, as $\min\{x, \widetilde{\alpha}\}$ is a solution of (1.2) with $x_0 = \alpha(t_0)$.

If $\omega \leqslant t_0 + T$ the lemma is proved. Suppose next that $t_0 + mT < \omega \leqslant t_0 + (m+1)T$ for some integer $m \geqslant 1$. In this case we may assume that $\tau_k = t_0 + kT$ for $k = 1, \dots, m$, and the T-monotonicity of $\widetilde{\alpha}$ follows from the minimality of the solutions v_n on $[\tau_{n-1}, \tau_n]$. Finally suppose that $\omega = +\infty$. In this case we may assume that $\tau_n = t_0 + nT$ for all n and the T-monotonicity of $\widetilde{\alpha}$ follows as in the previous case. Suppose further that $\limsup_{t \to +\infty} \widetilde{\alpha}(t) < +\infty$. Since $\widetilde{\alpha}$ is T-increasing, Proposition 1.7 implies that there exists a solution v of (1.3) such that $\widetilde{\alpha} \leqslant v$ on $[t_0, +\infty[$ and

$$\lim_{t \to +\infty} \bigl(\widetilde{\alpha}(t) - v(t)\bigr) = 0.$$

Note that v is the minimum solution in $[\alpha, +\infty[$ of (1.3), because the existence of a solution u of (1.3), such that $\alpha \leqslant u < v$, would contradict the minimality properties of $\widetilde{\alpha}$. □

REMARK 1.9. The following version of Proposition 1.8 for a terminal value problem holds.

(j) Let β be an upper solution of (1.3) and let $t_0 \in \mathbb{R}$. Then there exist $\omega \in [-\infty, t_0[$ and a T-decreasing solution $\widetilde{\beta} :]\omega, t_0] \to \mathbb{R}$ of the terminal value problem (1.2), with $x_0 = \beta(t_0)$, satisfying $\widetilde{\beta} \geqslant \beta$ on $]\omega, t_0]$. Further, every solution $x :]\tau, t_0] \to \mathbb{R}$ of (1.1), with $x \geqslant \beta$, is such that $\tau \geqslant \omega$ and $x \geqslant \widetilde{\beta}$ on $]\tau, t_0]$. Finally, we have that either every left-nonextendible solution $x :]\tau, t_0] \to \mathbb{R}$ of (1.1), with $x \geqslant \beta$, is such that

$$\limsup_{t \to \tau} x(t) = +\infty$$

and (1.3) has no solution in $[\beta, +\infty[$, or there exists the minimum solution v in $[\beta, +\infty[$ of (1.3); in the latter case $\omega = -\infty$, $v \geqslant \widetilde{\beta}$ and

$$\lim_{t \to -\infty} \bigl(\widetilde{\beta}(t) - v(t)\bigr) = 0.$$

(jj) Let α be a lower solution of (1.3) and let $t_0 \in \mathbb{R}$. Then there exist $\omega \in [-\infty, t_0[$ and a T-increasing solution $\widetilde{\alpha} :]\omega, t_0] \to \mathbb{R}$ of the terminal value problem (1.2), with $x_0 = \alpha(t_0)$, satisfying $\widetilde{\alpha} \leqslant \alpha$ on $]\omega, t_0]$. Further, every solution $x :]\tau, t_0] \to \mathbb{R}$ of (1.1), with $x \leqslant \alpha$, is such that $\tau \geqslant \omega$ and $x \leqslant \widetilde{\alpha}$ on $]\tau, t_0]$. Finally, we have that either every left-nonextendible solution $x :]\tau, t_0] \to \mathbb{R}$ of (1.1), with $x \leqslant \alpha$, is such that

$$\liminf_{t \to \tau} x(t) = -\infty,$$

and (1.3) has no solution in $]-\infty, \alpha]$, or there exists the maximum solution w in $]-\infty, \alpha]$ of (1.3); in the latter case $\omega = -\infty$, $w \leqslant \widetilde{\alpha}$ and

$$\lim_{t \to -\infty} \bigl(\widetilde{\alpha}(t) - w(t)\bigr) = 0.$$

Existence of solutions

The counterpart of Theorem 1.4 for the periodic problem (1.3) is the following theorem.

THEOREM 1.9. *Assume* (C). *Let α be a lower solution and β be an upper solution of* (1.3). *Then there exist the minimum solution v and the maximum solution w in* $[\min\{\alpha, \beta\}, \max\{\alpha, \beta\}]$ *of* (1.3).

PROOF. We distinguish three cases.

Case 1: $\alpha \leqslant \beta$. Let $\widetilde{\alpha}$ be the T-increasing solution of (1.2), with $x_0 = \alpha(t_0)$, whose existence is guaranteed by Proposition 1.8. Corollary 1.5, together with the minimality property of $\widetilde{\alpha}$, imply that $\widetilde{\alpha}$ is defined on $[t_0, +\infty[$ and $\widetilde{\alpha} \leqslant \beta$. Since $\widetilde{\alpha}$ is bounded, there exists the minimum solution v in $[\alpha, \beta]$ of (1.3). A symmetric argument proves the existence of the maximum solution w in $[\alpha, \beta]$ of (1.3).

Case 2: $\alpha > \beta$. We can reduce this case to the previous one by reversing time, as we did in Claim 2 of Lemma 1.2.

Case 3: $\alpha \nleqslant \beta$ *and* $\beta \nleqslant \alpha$. By Proposition 1.6 there exists $t_0 \in [0, T]$ such that $\alpha(t_0) = \beta(t_0)$. The result follows then immediately by Theorem 1.4 applied to problem (1.2), with $x_0 = \alpha(t_0) = \beta(t_0) = \alpha(t_0 + T) = \beta(t_0 + T)$, on the interval $[t_0, t_0 + T]$. □

We produce a simple example showing how Theorem 1.9 can be effectively applied to detect the existence of branches of T-periodic solutions by an appropriate choice of lower and upper solutions.

EXAMPLE 1.1. Let us consider the equation

$$x' = \sqrt{|x|} + h(t), \tag{1.12}$$

with $h : \mathbb{R} \to \mathbb{R}$ the 1-periodic function defined by $h(t) = -\frac{1}{8}|t|$ on $[-\frac{1}{2}, \frac{1}{2}[$. For any $p \in\,]-2^{-10}, 2^{-10}[$, define $\alpha_p : [-\frac{1}{2}, \frac{1}{2}[\, \to \mathbb{R}$, by setting $\alpha_p(-\frac{1}{2}) = p$ and $\alpha_p(t) = 2^{-4}\operatorname{sgn}(t)t^2$ on $]-\frac{1}{2}, \frac{1}{2}[$, and $\beta_p : [-\frac{1}{2}, \frac{1}{2}[\, \to \mathbb{R}$, by setting $\beta_p(-\frac{1}{2}) = p$ and $\beta_p(t) = -2^{-8}\operatorname{sgn}(t)t^2$ on $]-\frac{1}{2}, \frac{1}{2}[$. Then α_p and β_p are respectively a lower and an upper solution of the 1-periodic problem associated with (1.12). By Theorem 1.9, Eq. (1.12) has, for each $p \in\,]-2^{-10}, 2^{-10}[$, a 1-periodic solution u_p such that $u_p(-\frac{1}{2}) = p$.

A criterion of T-monotonicity

In the next theorem we show that T-monotonicity is a property shared by any solution of (1.1) which is comparable with all T-periodic solutions of (1.1).

THEOREM 1.10. *Assume* (C). *Let* $x :]\omega_-, \omega_+[\, \to \mathbb{R}$ *be a nonextendible solution of* (1.1) *such that, if u is a solution of* (1.3), *then either $x > u$ or $x < u$. Then x is T-monotone.*

PROOF. We assume that $\omega_+ - \omega_- > T$, because otherwise there is nothing to prove. Let us suppose by contradiction that x is not T-monotone, i.e. there are points $t_1, t_2 \in\,]\omega_-, \omega_+[$ such that

$$x(t_1) < x(t_1 + T) \quad \text{and} \quad x(t_2) > x(t_2 + T).$$

We can assume that $t_1 < t_2$, otherwise we set $y(t) = -x(t)$ and replace equation (1.1) with $y' = -f(t, -y)$.

Step 1. Assume $\omega_+ = +\infty$. We distinguish two cases.

• Suppose that there exists $n \in \mathbb{N}^+$ such that $t_2 = t_1 + nT$ and $x(t_1 + kT) \leqslant x(t_1 + (k + 1)T)$ for each $0 \leqslant k \leqslant n - 1$. Let $m \in \mathbb{N}$ be such that $x(t_1 + mT) < x(t_1 + (m + 1)T) = x(t_1 + nT)$. Since $\max\{x(t_1 + mT), x(t_1 + (n + 1)T)\} < x(t_1 + nT)$, we can pick $p \in\,]\max\{x(t_1 + mT), x(t_1 + (n + 1)T)\}, x(t_1 + nT)[$. We define a function $\alpha : [t_1 + mT, t_1 + (m + 1)T[\, \to \mathbb{R}$ by $\alpha(t) = x(t)$ on $]t_1 + mT, t_1 + (m + 1)T[$ and $\alpha(t_1 + mT) = p$, and a function $\beta:[t_1+nT,t_1+(n+1)T[\,\to\mathbb{R}$ by $\beta(t)=x(t)$ on $]t_1+nT,t_1+(n+1)T[$ and $\beta(t_1+nT)=p$. The T-periodic extensions to $\mathbb{R}$ of α and β are respectively a lower and an upper solution of (1.3). Hence Theorem 1.9 yields, for any $p\in\,]\max\{x(t_1+mT),x(t_1+(n+1)T)\},x(t_1+nT)[$, the existence of a solution u of (1.3) such that $\min\{\alpha,\beta\}\leqslant u\leqslant\max\{\alpha,\beta\}$. Since $u(t_1+mT)=p$ and $x(t_1+mT)<p<x(t_1+nT)$, we conclude that $u\nleqslant x$ and $u\ngeqslant x$, which is a contradiction.

- Suppose that there exists $n\in\mathbb{N}$ such that $t_1+nT<t_2<t_1+(n+1)T$ and $x(t_1+kT)\leqslant x(t_1+(k+1)T)$ for each $k\in\mathbb{N}$. Set $\varphi(t)=x(t+T)-x(t)$ on $]\omega_-,+\infty[$. As $\varphi(t_2)<0$ and $\varphi(t_1+(n+1)T)\geqslant 0$, there exists $s_1\in\,]t_2,t_1+(n+1)T]$ such that $\varphi(s_1)=0$, i.e. $x(s_1+T)=x(s_1)$. Let $v:\mathbb{R}\to\mathbb{R}$ be the T-periodic extension to $\mathbb{R}$ of $x|_{[s_1,s_1+T]}$; v is a solution of (1.3). Since $v(t_2)=v(t_2+T)=x(t_2+T)<x(t_2)$ and $v(t_1+nT)=v(t_1+(n+1)T)=x(t_1+(n+1)T)\geqslant x(t_1+nT)$, there exists $s_2\in[t_1+nT,t_2[$ such that $v(s_2)=x(s_2)$. Note that $x(s_2)=x(s_2+T)$. Let $w:\mathbb{R}\to\mathbb{R}$ be the T-periodic extension to $\mathbb{R}$ of $x|_{[s_2,s_2+T]}$; w is a solution of (1.3). Since $v(t_2)=x(t_2+T)<x(t_2)=w(t_2)$, we can pick $p\in\,]v(t_2),w(t_2)[$. Then we define a function $\alpha:[s_2,s_2+T[\,\to\mathbb{R}$, by $\alpha(t)=w(t)$ on $]s_2,t_2[$, $\alpha(t_2)=p$ and $\alpha(t)=v(t)$ on $]t_2,s_2+T[$, and a function $\beta:[s_2,s_2+T[\,\to\mathbb{R}$, by $\beta(t)=v(t)$ on $]s_2,t_2[$, $\beta(t_2)=p$ and $\beta(t)=w(t)$ on $]t_2,s_2+T[$. The T-periodic extensions to $\mathbb{R}$ of α and β are respectively a lower and an upper solution of (1.3). Hence Theorem 1.9 yields, for any $p\in\,]v(t_2),w(t_2)[$, the existence of a solution u of (1.3) such that $\min\{\alpha,\beta\}\leqslant u\leqslant\max\{\alpha,\beta\}$. Since $u(t_2)=p$ and $x(t_2+T)<p<x(t_2)$, we conclude that $u\nleqslant x$ and $u\ngeqslant x$, which is a contradiction.

Step 2. Assume $\omega_-=-\infty$. We set $y(t)=-x(-t)$ and we replace Eq. (1.1) with $y'=f(-t,-y)$. Thus we are reduced to the situation discussed in Step 1.

Step 3. Assume $\omega_-,\omega_+\in\mathbb{R}$. Set $\varphi(t)=x(t+T)-x(t)$ on $]\omega_-,\omega_+-T[$. We essentially distinguish two cases.

- Suppose that

$$\lim_{t\to\omega_-}x(t)=-\infty\quad\text{and}\quad\lim_{t\to\omega_+}x(t)=+\infty;\tag{1.13}$$

the case where $\lim_{t\to\omega_-}x(t)=+\infty$ and $\lim_{t\to\omega_+}x(t)=-\infty$ being treated similarly. Since $\varphi(t_1)>0>\varphi(t_2)$, there exists $t_0\in\,]t_1,t_2[$ such that $\varphi(t_0)=0$, i.e. $x(t_0+T)=x(t_0)$. Let $u:\mathbb{R}\to\mathbb{R}$ be the T-periodic extension to $\mathbb{R}$ of $x|_{[t_0,t_0+T]}$; u is a solution of (1.3). Since (1.13) implies that $u\nleqslant x$ and $u\ngeqslant x$, a contradiction follows.

- Suppose that

$$\lim_{t\to\omega_-}x(t)=\lim_{t\to\omega_+}x(t)=+\infty;\tag{1.14}$$

the case where $\lim_{t\to\omega_-}x(t)=\lim_{t\to\omega_+}x(t)=-\infty$ being treated similarly. Since $\lim_{t\to\omega_-}\varphi(t)=-\infty$ and $\lim_{t\to\omega_+-T}\varphi(t)=+\infty$, there exists $s_1\in\,]\omega_-,\omega_+-T[$ such that $\varphi(s_1)=0$, i.e. $x(s_1+T)=x(s_1)$. Let $w:\mathbb{R}\to\mathbb{R}$ be the T-periodic extension to $\mathbb{R}$ of $x|_{[s_1,s_1+T]}$. Since w is a solution of (1.3) and (1.14) holds, we conclude that $x>w$ and w is the maximum solution of (1.3). Define a function $x_1:\,]\omega_-,\omega_+-T[\,\to\mathbb{R}$ by setting $x_1(t)=x(t)$ on $]\omega_-,s_1]$ and $x_1(t)=x(t+T)$ on $]s_1,\omega_+-T[$. The function x_1 is a solution of (1.1) satisfying $x_1>w$ on $]\omega_-,\omega_+-T[$, $x_1(s_1)=w(s_1)$ and $\lim_{t\to\omega_-}x_1(t)=$

$\lim_{t\to\omega_+-T} x_1(t) = +\infty$. Proceeding recursively we can find $s_n \in]\omega_-, \omega_+ - nT[$ and construct a solution $x_n :]\omega_-, \omega_+ - nT[\to \mathbb{R}$ of (1.1) such that $\omega_+ - nT - \omega_- \leqslant T$, $x_n > w$ on $]\omega_-, \omega_+ - nT[$, $x_n(s_n) = w(s_n)$ and $\lim_{t\to\omega_-} x_n(t) = \lim_{t\to\omega_+-nT} x_n(t) = +\infty$. A contradiction will then be achieved from the following result.

CLAIM. *Assume that there exists the maximum solution w of* (1.3). *Let $x :]\omega_-, \omega_+[\to \mathbb{R}$ be a solution of* (1.1) *such that $\omega_+ - \omega_- \leqslant T$, $x > w$ on $]\omega_-, \omega_+[$ and* $\lim_{t\to\omega_-} x(t) = \lim_{t\to\omega_+} x(t) = +\infty$. *Then $x \gg w$ on $]\omega_-, \omega_+[$.*

Suppose by contradiction that there is $t_0 \in]\omega_-, \omega_+[$ such that $x(t_0) = w(t_0)$ and $x(t) > w(t)$ on $]t_0, \omega_+[$. Denote by $\mathcal{Y}$ the set of all solutions $y : [t_0, \lambda_+(y)[\to \mathbb{R}$ of (1.1), which are nonextendible to the right of $\lambda_+(y)$ and satisfy $y(t_0) = w(t_0)$, $y \geqslant w$ on $[t_0, \lambda_+(y)[$ and $y > w$ on $[t_0, \omega_- + T[\cap [t_0, \lambda_+(y)[$. Note that $\mathcal{Y} \neq \emptyset$, as $x \in \mathcal{Y}$. Set $\lambda_+ = \sup_{y\in\mathcal{Y}} \lambda_+(y)$. Let us show that $\lambda_+ > \omega_- + T$. Otherwise, if $\lambda_+ \leqslant \omega_- + T$, we can pick a solution $z : [\lambda_+ - \delta, \lambda_+ + \delta] \to \mathbb{R}$ of (1.1) such that $z(\lambda_+) > w(\lambda_+)$. Let $y \in \mathcal{Y}$ be such that $\lambda_+(y) > \lambda_+ - \delta$. As $\lim_{t\to\lambda_+(y)} y(t) = +\infty$, we can suppose, possibly for a smaller $\delta > 0$, that $y(t) > z(t)$ on $[\lambda_+ - \delta, \lambda_+(y)[$. Hence z can be continued to a right-nonextendible solution v of (1.1) defined on $[t_0, \lambda_+(v)[$, with $\lambda_+(v) > \lambda_+ + \delta$, and satisfying $v(t_0) = w(t_0)$, $v \geqslant w$ on $[t_0, \lambda_+(v)[$ and $v > w$ on $[t_0, \omega_- + T[\cap [t_0, \lambda_+(v)[$. Since $v \in \mathcal{Y}$ we get a contradiction. Therefore $\lambda_+ > \omega_- + T$. Pick $y \in \mathcal{Y}$ such that $\lambda_+(y) > \omega_- + T$. As $\lim_{t\to(\omega_-+T)^+} x(t - T) = +\infty$, there is $\delta > 0$ such that $w(t) \leqslant y(t) < x(t - T)$ on $]\omega_- + T, \omega_- + T + \delta]$. Hence y can be continued to a solution u of (1.1) defined on $[t_0, t_0 + T]$ and satisfying $w(t) \leqslant u(t) \leqslant x(t - T)$ on $]\omega_- + T, t_0 + T]$. Since u is a solution of (1.3) and $u > w$ on $[t_0, \omega_- + T]$, the maximality of w yields a contradiction. Therefore the claim is proved. □

REMARK 1.10. The following more general conclusion can be achieved. Let $x :]\omega_-, \omega_+[\to \mathbb{R}$ be a nonextendible solution of (1.1) such that $\omega_-, \omega_+ \in \mathbb{R}$, $\omega_+ - \omega_- \leqslant T$ and, for any solution u of (1.3), either $x < u$ or $x > u$. Then two possibilities may occur:

- for all solutions u of (1.3), either $x \ll u$ or $x \gg u$;
- there exist a solution u of (1.3) and $t_0 \in]\omega_-, \omega_+[$ such that $u(t_0) = x(t_0)$ and, e.g., $u < x$. In this case there exists $\bar{t} \in]t_0, t_0 + T[$ such that, for every $\bar{x} > u(\bar{t})$, there is a solution v of (1.3) with $u < v < x$ on $]\omega_-, \omega_+[$ and $v(\bar{t}) = \bar{x}$.

A simple example where the latter possibility occurs follows.

EXAMPLE 1.2. Let us consider Eq. (1.1) taking $f : [-\frac{3}{2}, \frac{3}{2}[\times \mathbb{R} \to \mathbb{R}$ defined by $f(t, x) = 2x^2 \operatorname{sgn}(t)$, if $|x| > 1$, and $f(t, x) = 2\sqrt{|x|} \operatorname{sgn}(t)$, if $|x| \leqslant 1$, and extending f by 3-periodicity with respect to the t-variable. Let $x :]-\frac{3}{2}, \frac{3}{2}[\to \mathbb{R}$ be defined by $x(t) = \frac{1}{3+2t}$ on $]-\frac{3}{2}, -1]$, $x(t) = t^2$ on $]-1, 1]$, $x(t) = \frac{1}{3-2t}$ on $]1, \frac{3}{2}[$. Note that x is a nonextendible solution of (1.1) such that $x > u$ for any solution u of (1.3), 0 is a solution of (1.3), $x(0) = 0$ and, for every $\bar{x} > 0$, there is a solution v of (1.3) with $0 < v < x$ on $] - \frac{3}{2}, \frac{3}{2}[$ and $v(\frac{3}{2}) = \bar{x}$.

The Massera Existence Theorem

When uniqueness of solutions of (1.2) fails, there may exist solutions which are not T-monotone (see Example 1.3). It is useful to notice that existence of a solution that is not T-monotone yields existence of T-periodic solutions. Proposition 1.38 will actually show that infinitely many T-periodic solutions do exist in this case.

COROLLARY 1.11. *Assume* (C). *Let* $x :]t_0, +\infty[\to \mathbb{R}$ *be a solution of* (1.1). *If* x *is not* T*-monotone, then there exists a solution* u *of* (1.3) *such that* $u \nleqslant x$ *and* $u \ngeqslant x$.

PROOF. Since x is not T-monotone, there are points $t_1, t_2 \in]t_0, +\infty[$ such that $x(t_1) < x(t_1 + T)$ and $x(t_2) > x(t_2 + T)$. Hence we can proceed as in the first step of the proof of Theorem 1.10 to get the conclusion. □

We finally observe that combining Corollary 1.11 and Proposition 1.7 immediately yields the following statement.

PROPOSITION 1.12. *Assume* (C). *Suppose that Eq.* (1.1) *has a bounded solution defined on an unbounded interval. Then problem* (1.3) *has at least one solution.*

Proposition 1.12 provides an extension to the Carathéodory setting of the existence part of the Massera Theorem. Yet, it must be observed that, when uniqueness for (1.1) fails, convergence of a bounded solution x to a T-periodic solution u is not generally guaranteed, as the following example will show. A possible extension of the convergence part of the Massera Theorem to the case where the uniqueness assumption is dropped will be discussed in Section 1.7.

EXAMPLE 1.3. We consider Eq. (1.12) again. As described in Example 1.1, for each $p \in]-2^{-10}, 2^{-10}[$, there exists a 1-periodic solution u_p of (1.12) such that $u_p(-\frac{1}{2}) = p$ and $u_p(0) = 0$. Let $p_1 \neq p_2$ and set $x(t) = u_{p_1}(t)$ on $[0, 1[$ and $x(t) = u_{p_2}(t)$ on $[1, 2[$. Since $x(\frac{1}{2}) = p_1 \neq p_2 = x(\frac{3}{2})$, the extension to $\mathbb{R}$ of x by 2-periodicity is a 2-periodic solution of (1.12) which is not 1-periodic; hence it is a bounded solution which does not converge to any 1-periodic solution of (1.12). As we shall see in Example 1.4, x is a subharmonic solution of order 2 of (1.12), i.e. its minimal period is 2.

1.5. *Structure and dynamics near one-sided isolated periodic solutions*

We investigate in this section the dynamics of all solutions of (1.1) in the vicinity of one-sided isolated T-periodic solutions; namely, solutions of (1.1) which lie between a pair of strictly ordered T-periodic solutions, or above the maximum T-periodic solution, or below the minimum T-periodic solution, provided they exist. T-monotonicity plays an important role in this study. Incidentally we notice that the maximum solution of (1.3) always exists, provided the solution set of (1.3) is bounded from above. Similarly the minimum solution of (1.3) always exists, provided the solution set of (1.3) is bounded from below.

Between two ordered T*-periodic solutions*
We start by observing that, given a pair of T-periodic solutions, either they are strictly ordered, or there exist infinitely many T-periodic solutions hitting them.

PROPOSITION 1.13. *Assume* (C). *Let* v, w *be solutions of* (1.3), *with* $v \neq w$. *Then either* $v \ll w$, *or* $v \gg w$, *or for every* $t_0 \in [0, T[$ *and every* $x_0 \in [\min\{v(t_0), w(t_0)\}, \max\{v(t_0), w(t_0)\}]$ *there exists a solution* u *of* (1.3) *with* $u(t_0) = x_0$ *and* $\min\{v, w\} \leqslant u \leqslant \max\{v, w\}$.

PROOF. Assume that there exists $\bar{t} \in [0, T[$ such that $v(\bar{t}) = w(\bar{t})$. Let $t_0 \in [0, T]$ and $x_0 \in [\min\{v(t_0), w(t_0)\}, \max\{v(t_0), w(t_0)\}]$. We may assume that $t_0 \leqslant \bar{t}$, otherwise we replace $\bar{t}$ with $\bar{t} + T$. Let us consider the T-periodic functions α and β defined by $\alpha(t_0) = x_0$, $\alpha(t) = \min\{v(t), w(t)\}$ on $]t_0, \bar{t}]$, $\alpha(t) = \max\{v(t), w(t)\}$ on $]\bar{t}, t_0 + T[$, $\beta(t_0) = x_0$, $\beta(t) = \max\{v(t), w(t)\}$ on $]t_0, \bar{t}]$, $\beta(t) = \min\{v(t), w(t)\}$ on $]\bar{t}, t_0 + T[$. Then α and β are respectively a lower solution and an upper solution of (1.3), hence, by Theorem 1.9, there exists a solution u of (1.3) with $\min\{\alpha, \beta\} \leqslant u \leqslant \max\{\alpha, \beta\}$. In particular $u(t_0) = x_0$ and $\min\{v, w\} \leqslant u \leqslant \max\{v, w\}$. □

We consider here the case where a pair of strictly ordered T-periodic solutions is given, the complementary situation will be discussed in Section 1.6. We prove the existence of heteroclinic solutions connecting a pair of strictly ordered T-periodic solutions, when there is no further T-periodic solution in between.

THEOREM 1.14. *Assume* (C). *Let v, w be solutions of* (1.3) *such that $v \ll w$ and there is no solution u of* (1.3) *satisfying $v < u < w$. Then either any nonextendible solution x of* (1.1), *with $v < x < w$, exists on $\mathbb{R}$, is T-increasing and satisfies*

$$\lim_{t \to -\infty} \bigl(x(t) - v(t)\bigr) = \lim_{t \to +\infty} \bigl(x(t) - w(t)\bigr) = 0,$$

or any nonextendible solution x of (1.1), *with $v < x < w$, exists on $\mathbb{R}$, is T-decreasing and satisfies*

$$\lim_{t \to -\infty} \bigl(x(t) - w(t)\bigr) = \lim_{t \to +\infty} \bigl(x(t) - v(t)\bigr) = 0.$$

PROOF. Pick any nonextendible solution x of (1.1), with $v < x < w$. Clearly, there is a t_0 such that $v(t_0) < x(t_0) < w(t_0)$. Since x exists on $\mathbb{R}$ and satisfies the assumptions of Theorem 1.10, we have that either x is T-increasing, or x is T-decreasing. Assume the former case occurs, the latter one being treated similarly. Then Proposition 1.7 and Remark 1.7 imply that there exist solutions u_1, u_2 of (1.3) satisfying $u_1 < x < u_2$, as x is not a solution of (1.3), and $\lim_{t \to -\infty}(x(t) - u_1(t)) = \lim_{t \to +\infty}(x(t) - u_2(t)) = 0$. Since $v \leqslant u_1 < u_2 \leqslant w$ and there is no solution u of (1.3) satisfying $v < u < w$, we conclude that $u_1 = v$ and $u_2 = w$.

Finally, let us suppose by contradiction that there exist two solutions x_1, x_2 of (1.1), with $v < x_1 < w$ and $v < x_2 < w$ on $\mathbb{R}$, such that $\lim_{t \to -\infty}(x_1(t) - v(t)) = \lim_{t \to +\infty}(x_1(t) - w(t)) = 0$ and $\lim_{t \to -\infty}(x_2(t) - w(t)) = \lim_{t \to +\infty}(x_2(t) - v(t)) = 0$. Set $x_* = \min\{x_1, x_2\}$ and $x^* = \max\{x_1, x_2\}$. Since either $v < x_* < w$, or $v < x^* < w$, we find a solution x of (1.1), with $v < x < w$ in $\mathbb{R}$, such that either $\lim_{t \to -\infty}(x(t) - v(t)) = \lim_{t \to +\infty}(x(t) - v(t)) = 0$, or $\lim_{t \to -\infty}(x(t) - w(t)) = \lim_{t \to +\infty}(x(t) - w(t)) = 0$, thus contradicting the conclusion previously achieved. □

Maximal and minimal T-periodic solutions

We show now that any bounded set of solutions of (1.3) has a maximal and a minimal element.

LEMMA 1.15. *Assume* (C). *Let* $\mathcal{S} \subseteq W^{1,1}(0,T)$ *be a nonempty set of solutions of* (1.3). *Assume that* $\mathcal{S}$ *is uniformly bounded from above, i.e. there exists a constant* M *such that* $\max_{[0,T]} u(t) \leqslant M$ *for all* $u \in \mathcal{S}$. *Then there exists a maximal solution* w *of* (1.3) *in the* C^0*-closure* $\bar{\mathcal{S}}$ *of* $\mathcal{S}$. *Similarly, if* $\mathcal{S}$ *is uniformly bounded from below, then there exists a minimal solution* v *of* (1.3) *in* $\bar{\mathcal{S}}$.

PROOF. We only prove the former case. We show that $(\bar{\mathcal{S}}, \leqslant)$ is inductively ordered. Let $\mathcal{T} = \{u_i \mid i \in I\}$ be a totally ordered subset of $\bar{\mathcal{S}}$. We prove that $\mathcal{T}$ has an upper bound in $\bar{\mathcal{S}}$. Let us set $u(t) = \sup_{i\in I} u_i(t)$ on $[0,T]$. Let $\mathcal{D} = \{t_m \mid m \in \mathbb{N}\}$ be a countable dense subset of $[0,T]$ and define a sequence in $\mathcal{T}$ as follows: for $n=1$, take $u_1 \in \mathcal{T}$ such that $u_1(t_1) \geqslant u(t_1) - 1$, for $n=2$, take $u_2 \in \mathcal{T}$, with $u_2 \geqslant u_1$, such that $u_2(t_2) \geqslant u(t_2) - \frac{1}{2}$, $u_2(t_1) \geqslant u(t_1) - \frac{1}{2}$, and so on. In this way, we construct a sequence $(u_n)_n$ in $\mathcal{T}$, with $u_1 \leqslant u_2 \leqslant \cdots \leqslant u_n \leqslant u_{n+1} \leqslant \cdots$, such that $u_n(t_k) \geqslant u(t_k) - \frac{1}{n}$, for $1 \leqslant k \leqslant n$. It is clear that $(u_n)_n$ converges to u pointwise on $\mathcal{D}$. On the other hand, as $(u_n)_n$ is relatively compact in $C^0([0,T])$, there is a subsequence of $(u_n)_n$ which converges uniformly to some function $\hat{u} \in C^0([0,T])$. Actually, by monotonicity, the whole sequence $(u_n)_n$ converges uniformly to $\hat{u}$. Using the L^1-Carathéodory conditions, we conclude that the convergence takes place in $W^{1,1}(0,T)$, the limit $\hat{u} \in W^{1,1}(0,T)$ and $\hat{u}$ is a solution of (1.3). Moreover, $\hat{u} = u$ on $\mathcal{D}$ and $\hat{u} \leqslant u$ on $[0,T]$. Let us show that $\hat{u} = u$ on $[0,T]$. Indeed, otherwise, one can find a point $t_0 \in [0,T]$ and a function $u_0 \in \mathcal{T}$ such that $\hat{u}(t_0) < u_0(t_0) \leqslant u(t_0)$. The continuity of $\hat{u}$ and u_0 and the density of $\mathcal{D}$ yield a contradiction. This proves that $u \in \bar{\mathcal{S}}$ is an upper bound of $\mathcal{T}$. Since $(\bar{\mathcal{S}}, \leqslant)$ is inductively ordered, Zorn Lemma guarantees the existence of a maximal element $w \in \bar{\mathcal{S}}$. □

By the lattice structure of the solution set of (1.3), we get the following conclusion.

COROLLARY 1.16. *Suppose* (C). *Assume that the set of all solutions of* (1.3) *is uniformly bounded from above. Then there exists the maximum solution of* (1.3). *Assume that the set of all solutions of* (1.3) *is uniformly bounded from below. Then there exists the minimum solution of* (1.3).

Above the maximum, or below the minimum T-periodic solution

We now assume that there exists the maximum solution of (1.3) and describe the qualitative behaviour of all solutions of (1.1) that lie above it. Symmetric conclusions can be established for solutions lying below the minimum T-periodic solution, whenever it exists.

THEOREM 1.17. *Assume* (C). *Suppose that there exists the maximum solution* w *of* (1.3). *Then either any nonextendible solution* x *of* (1.1), *with* $x > w$, *is* T*-increasing or any nonextendible solution* x *of* (1.1), *with* $x > w$, *is* T*-decreasing. Furthermore, for any such* $x :]\omega_-, \omega_+[\to \mathbb{R}$, *either*

$$\omega_-, \omega_+ \in \mathbb{R}, \quad \omega_+ - \omega_- \leqslant T, \quad x \gg w \quad \textit{on }]\omega_-, \omega_+[\quad \textit{and}$$

$$\lim_{t\to\omega_-} x(t) = \lim_{t\to\omega_+} x(t) = +\infty,$$

or

$$\omega_- = -\infty, \quad \lim_{t\to-\infty}\big(x(t) - w(t)\big) = 0 \quad \textit{and} \quad \limsup_{t\to\omega_+} x(t) = +\infty,$$

or

$$\omega_+ = +\infty, \quad \limsup_{t\to\omega_-} x(t) = +\infty \quad \textit{and} \quad \lim_{t\to+\infty}\big(x(t) - w(t)\big) = 0.$$

PROOF. Let $x :]\omega_-, \omega_+[\to \mathbb{R}$ be a nonextendible solution of (1.1) with $x > w$.

Assume first that $\omega_-, \omega_+ \in \mathbb{R}$ and that $\omega_+ - \omega_- \leqslant T$. The Claim stated in the proof of Theorem 1.10 implies that $x \gg w$ on $]\omega_-, \omega_+[$. Then the conclusion follows.

Suppose next that $\omega_+ - \omega_- > T$. By Theorem 1.10 either x is T-increasing, or x is T-decreasing. Assume that the former situation occurs, the latter case being treated similarly. Since x is bounded from below, we have $\omega_- = -\infty$. Let us verify that $\lim_{t\to-\infty}(x(t) - w(t)) = 0$. Remark 1.7 implies that there exists a solution u of (1.3), with $u \leqslant x$, such that $\lim_{t\to-\infty}(x(t) - u(t)) = 0$. Since $u \geqslant w$, the maximality of w yields $u = w$. Of course, if $\omega_+ < +\infty$, then $\lim_{t\to\omega_+} x(t) = +\infty$. Let us show that, if $\omega_+ = +\infty$, then $\limsup_{t\to\omega_+} x(t) = +\infty$. Indeed, otherwise, x would be bounded and Proposition 1.7 would imply the existence of a solution u of (1.3), with $u \geqslant x$, such that $\lim_{t\to+\infty}(x(t) - u(t)) = 0$. Since $u > w$, the maximality of w would yield a contradiction.

Finally, let us suppose, by contradiction, that there exist $x_1 :]-\infty, \omega_+[\to \mathbb{R}$, $x_2 :]\omega_-, +\infty[\to \mathbb{R}$ both solutions of (1.1), with $x_1 > w$ and $x_2 > w$, such that x_1 is T-increasing and x_2 is T-decreasing. Then $\lim_{t\to-\infty}(x_1(t) - w(t)) = 0$ and $\lim_{t\to+\infty}(x_2(t) - w(t)) = 0$. Possibly replacing $x_1(t)$ with $x_1(t - kT)$ for some $k \in \mathbb{N}$, we may assume $\omega_+ > \omega_-$. Set $x_* = \min\{x_1, x_2\}$ and $x^* = \max\{x_1, x_2\}$. Then either $w < x_*$ or $w \not\ll x^*$; in both cases we contradict the conclusions previously achieved. □

1.6. *Stability and detours*

In this section we study the stability properties of T-periodic solutions of (1.1) with the aid of lower and upper solutions. We start by recalling the classical notion of one-sided Lyapunov stability. Yet, in the present context, where uniqueness of the solutions of (1.2) is not guaranteed, such a definition does not generally seem the most appropriate to be considered; indeed, some weaker concept might fit better in order to detect certain residual forms of stability. As an alternative notion to Lyapunov stability we use order stability; this is common in the frame of monotone dynamical systems [93,58,60] and appears suited to our approach based on lower and upper solutions. Lyapunov stability implies order stability, but not vice versa; however, these concepts are equivalent if uniqueness, either in the past or in the future, holds for solutions of (1.2). We further give a characterization of order stability in terms of the asymptotic behaviour of solutions of (1.1) by introducing a third kind of stability, which is named weak stability. This notion was first defined in [130] in the context of multivalued dynamical systems (see also [50]) and is related to that of weak positive invariance considered in [105,152]. We show that weak stability and order stability are always equivalent. Using these concepts, we give a precise description of the stability properties of a T-periodic solution in terms of the existence of a lower or an upper solution close to it. Hence, when a pair of lower and upper solutions is given, we can discuss the stability or instability of the minimum and the maximum T-periodic solutions v and w wedged between them, thus getting a completion of Theorem 1.9. Afterwards, we turn to investigate the behaviour of the solutions lying between v and w. If the lower and the upper solutions are ordered in the standard way, i.e. the lower solution is below the upper solution, we find between v and w a totally ordered continuum of weakly stable T-periodic solutions. Whereas, in the complementary case we see that Lyapunov instability always occurs and, in the absence of uniqueness for (1.2), solutions of (1.1) having very complicated, even chaotic-like, dynamics may exist. In particular, we can find homoclinics, subharmonics of any order and almost periodic solutions, which are not periodic of any fixed period.

One-sided Lyapunov stability

DEFINITION 1.14.

- A solution u of (1.3) is said *Lyapunov stable* (briefly, *$\mathcal{L}$-stable*) *from below* if, for every $\varepsilon > 0$, there is $\delta > 0$ such that, for every $t_0 \in [0, T[$ and every x_0 with $u(t_0) - \delta < x_0 < u(t_0)$, every right-nonextendible solution x of (1.2), with $x \leqslant u$, exists on $[t_0, +\infty[$ and satisfies

$$u(t) - \varepsilon < x(t) \leqslant u(t) \quad \text{on } [t_0, +\infty[. \tag{1.15}$$

- If, further,

$$\lim_{t \to +\infty} \bigl(x(t) - u(t)\bigr) = 0, \tag{1.16}$$

  u is said *$\mathcal{L}$-asymptotically stable from below*.
- *$\mathcal{L}$-stability* and *$\mathcal{L}$-asymptotic stability from above* are defined similarly.
- A solution u of (1.3) is said *$\mathcal{L}$-stable* if, for every $\varepsilon > 0$, there is $\delta > 0$ such that, for every $t_0 \in [0, T[$ and every x_0 with $|x_0 - u(t_0)| < \delta$, every right-nonextendible solution x of (1.2) exists on $[t_0, +\infty[$ and satisfies

$$\bigl|x(t) - u(t)\bigr| < \varepsilon \quad \text{on } [t_0, +\infty[. \tag{1.17}$$

  If, further, (1.16) holds, u is said *$\mathcal{L}$-asymptotically stable*.
- A solution u of (1.3) is said *$\mathcal{L}$-unstable from below* if it is not $\mathcal{L}$-stable from below. *$\mathcal{L}$-instability from above* and *$\mathcal{L}$-instability* are defined similarly.

REMARK 1.11. The notion of $\mathcal{L}$-stability from below given in Definition 1.14 does not require any condition on solutions $x : [t_0, \omega_+[\to \mathbb{R}$ of (1.2), satisfying $u(t_0) - \delta < x_0 < u(t_0)$, but not $x \leqslant u$. A similar remark holds for the $\mathcal{L}$-stability from above.

DEFINITION 1.15. A solution u of (1.3) is said *isolated from below* in $C^0([0, T])$ if there exists $\varepsilon > 0$ such that no solution z of (1.3) exists satisfying $u - \varepsilon < z < u$. Similarly, a solution u of (1.3) is said *isolated from above* in $C^0([0, T])$ if there exists $\varepsilon > 0$ such that no solution z of (1.3) exists satisfying $u < z < u + \varepsilon$.

PROPOSITION 1.18. *Assume* (C). *A solution u of* (1.3) *is $\mathcal{L}$-asymptotically stable from below* (*respectively $\mathcal{L}$-asymptotically stable from above*) *if and only if it is $\mathcal{L}$-stable from below and isolated from below* (*respectively $\mathcal{L}$-stable from above and isolated from above*) *in $C^0([0, T])$.*

PROOF. Assume u is $\mathcal{L}$-asymptotically stable from below, then u is clearly $\mathcal{L}$-stable and isolated from below in $C^0([0, T])$ as a solution of (1.3). Suppose now that u is $\mathcal{L}$-stable from below and isolated from below. Let $\varepsilon > 0$ be such that no solution z of (1.3) exists satisfying $u - \varepsilon < z < u$. By the $\mathcal{L}$-stability from below of u, there is $\delta > 0$ such that every right-nonextendible solution x of (1.2), with $u(t_0) - \delta < x_0 < u(t_0)$ and $x \leqslant u$, exists on $[t_0, +\infty[$ and satisfies $u - \varepsilon/2 < x < u$ on $[t_0, +\infty[$. We claim that any such solution x satisfies $x(t_0) < x(t_0 + T)$. Indeed, otherwise $x|_{[t_0,t_0+T[}$ is a proper upper solution of (1.3). Hence, by Proposition 1.8 there exists a solution v of (1.3) such that $\lim_{t\to+\infty}(x(t) - v(t)) = 0$ and $u - \varepsilon < v < x < u$ on $[t_0, t_0 + T]$, thus contradicting the assumption that u is isolated from below. Hence $x|_{[t_0,t_0+T[}$ is a proper lower solution of (1.3) and, by Proposition 1.8, $\lim_{t\to+\infty}(u(t) - x(t)) = 0$. A similar argument proves the statement about $\mathcal{L}$-stability from above. □

One-sided order stability

DEFINITION 1.16.

- A solution u of (1.3) is said *order stable* (briefly, *$\mathcal{O}$-stable*) (respectively *properly $\mathcal{O}$-stable*, respectively *strictly $\mathcal{O}$-stable*) *from below* if there exists a sequence $(\alpha_n)_n$ of regular lower solutions (respectively proper regular lower solutions, respectively strict regular lower solutions) of (1.3) such that $\alpha_n < u$ for every n and $\alpha_n \to u$ uniformly on $[0, T]$.
- A solution u of (1.3) is said *$\mathcal{O}$-stable* (respectively *properly $\mathcal{O}$-stable*, respectively *strictly $\mathcal{O}$-stable*) *from above* if there exists a sequence $(\beta_n)_n$ of regular upper solutions (respectively proper regular upper solutions, respectively strict regular upper solutions) of (1.3) such that $\beta_n > u$ for every n and $\beta_n \to u$ uniformly on $[0, T]$.
- A solution u of (1.3) is said *$\mathcal{O}$-stable* (respectively *properly $\mathcal{O}$-stable*, respectively *strictly $\mathcal{O}$-stable*) if it is $\mathcal{O}$-stable (respectively properly $\mathcal{O}$-stable, respectively strictly $\mathcal{O}$-stable) from above and from below.

REMARK 1.12. The requirement for the lower and upper solutions to be regular in Definition 1.16 is not essential. Indeed, we see, for instance, that between a proper lower solution α and a solution u of (1.3), with $\alpha < u$, it is always possible to fit in a proper regular lower solution $\bar{\alpha}$. This follows from Proposition 1.20. A similar observation holds for a proper upper solution β.

In order to prove Proposition 1.20 we first need the following result concerning a property of Carathéodory functions. A more general version of it will be proved in Proposition 2.3.

PROPOSITION 1.19. *Assume* (C). *Then, for each* $\rho > 0$, *there exists a* L^1*-Carathéodory function* $h : [0, T] \times [-\rho, \rho] \times [-\rho, \rho] \to \mathbb{R}$ *such that*

(i) *for a.e.* $t \in [0, T]$ *and every* $x \in [-\rho, \rho]$, $h(t, \cdot, x) : [-\rho, \rho] \to \mathbb{R}$ *is strictly increasing*;

(ii) *for a.e.* $t \in [0, T]$ *and every* $y \in [-\rho, \rho]$, $h(t, y, \cdot) : [-\rho, \rho] \to \mathbb{R}$ *is strictly decreasing*;

(iii) *for a.e.* $t \in [0, T]$ *and every* $(x, y) \in [-\rho, \rho] \times [-\rho, \rho]$, $h(t, x, y) = -h(t, y, x)$;

(iv) *for a.e.* $t \in [0, T]$ *and every* $(x, y) \in [-\rho, \rho] \times [-\rho, \rho]$, *with* $x < y$,

$$\left| f(t, y) - f(t, x) \right| < h(t, y, x).$$

PROPOSITION 1.20. *Assume* (C). *Suppose that* u *is a solution of* (1.3). *If* α *is a proper lower solution of* (1.3), *with* $\alpha < u$, *then there exists a proper regular lower solution* $\bar{\alpha}$ *of* (1.3), *satisfying* $\lim_{t\to 0^+} \bar{\alpha}(t) = \bar{\alpha}(0) = \lim_{t\to T^-} \bar{\alpha}(t)$ *and* $\alpha < \bar{\alpha} < u$. *Similarly, if* β *is a proper upper solution of* (1.3), *with* $\beta > u$, *then there exists a proper regular upper solution* $\bar{\beta}$ *of* (1.3), *satisfying* $\lim_{t\to 0^+} \bar{\beta}(t) = \bar{\beta}(0) = \lim_{t\to T^-} \bar{\beta}(t)$ *and* $u < \bar{\beta} < \beta$.

PROOF. Let h be the function associated with f by Proposition 1.19 and corresponding to $\rho = \max\{\|\alpha\|_\infty, \|u\|_\infty\}$. Consider the periodic problem

$$x' = f(t, \alpha) - h(t, x, \alpha), \quad x(0) = x(T).$$

Since α is a proper lower solution and u is a proper upper solution, this problem has a solution $\bar{\alpha}$, satisfying $\alpha < \bar{\alpha} < u$. The properties of h imply that $\bar{\alpha}$ is a proper lower solution of (1.3). $\square$

Lyapunov stability and order stability

We prove now that $\mathcal{L}$-stability implies $\mathcal{O}$-stability. We start with a result, which establishes the $\mathcal{O}$-stability of an isolated solution of (1.3) in the presence of a lower or an upper solution.

PROPOSITION 1.21. *Assume* (C). *Suppose that* z *is a solution of* (1.3).

- *If* α *is a proper lower solution of* (1.3) *such that* $\alpha < z$ *and there is no solution* u *of* (1.3) *satisfying* $\alpha < u < z$, *then there exists a sequence* $(\alpha_n)_n$ *of proper regular lower solutions of* (1.3), *with* $\alpha < \alpha_n < \alpha_{n+1} < z$ *for each* n, *which converges in* $W^{1,1}(0, T)$ *to* z.
- *If* β *is a proper upper solution of* (1.3) *such that* $\beta > z$ *and there is no solution* u *of* (1.3) *satisfying* $z < u < \beta$, *then there exists a sequence* $(\beta_n)_n$ *of proper regular upper solutions of* (1.3), *with* $z < \beta_{n+1} < \beta_n < \beta$ *for each* n, *which converges in* $W^{1,1}(0, T)$ *to* z.

PROOF. We only prove the statement concerning the lower solution. Repeating recursively the argument in the proof of Proposition 1.20, we get a sequence $(\alpha_n)_n$ of proper regular lower solutions of (1.3) such that, for each n, $\alpha < \alpha_n < \alpha_{n+1} < z$ and α_{n+1} is a solution of

$$x' = f(t, \alpha_n) - h(t, x, \alpha_n), \quad x(0) = x(T).$$

Since $(\alpha_n)_n$ is a bounded sequence, we see, arguing as in the proof of Proposition 1.7, that $(\alpha_n)_n$ converges in $W^{1,1}(0, T)$ to a function $\hat{\alpha}$ such that $\hat{\alpha} \leqslant z$ and $\hat{\alpha}(0) = \hat{\alpha}(T)$. Moreover, as $\lim_{n\to+\infty} h(t, \alpha_{n+1}(t), \alpha_n(t)) = 0$ a.e. on $[0, T]$, we see that $\hat{\alpha}$ is a solution of (1.3) and, hence, $\hat{\alpha} = z$. □

PROPOSITION 1.22. *Assume* (C). *If a solution u of* (1.3) *is $\mathcal{L}$-stable from below* (*respectively $\mathcal{L}$-stable from above*, *respectively $\mathcal{L}$-stable*), *then it is $\mathcal{O}$-stable from below* (*respectively $\mathcal{O}$-stable from above*, *respectively $\mathcal{O}$-stable*).

PROOF. Let u be a solution of (1.3) which is $\mathcal{L}$-stable from below. If u is not isolated from below in $C^0([0, T])$ as a solution of (1.3), there is a sequence $(\alpha_n)_n$ of (regular lower) solutions of (1.3) such that $\alpha_n < u$ for every n and $\alpha_n \to u$ uniformly on $[0, T]$, that is, u is $\mathcal{O}$-stable from below. Let us suppose that u is isolated from below in $C^0([0, T])$. Then, arguing as in the proof of Proposition 1.18, we can construct a proper lower solution α of (1.3) such that $\alpha < u$ and there is no solution w of (1.3) with $\alpha < w < u$. By Proposition 1.21, we conclude that u is $\mathcal{O}$-stable from below. □

REMARK 1.13. The converse of Proposition 1.22 does not generally hold. Indeed, there may exist solutions of (1.3) which are $\mathcal{O}$-stable, but $\mathcal{L}$-unstable. A simple example is given by (1.3), with $f(x) = \operatorname{sgn}(x)\sqrt{|x \sin(\frac{1}{x})|}$ if $x \neq 0$ and $f(x) = 0$ if $x = 0$. Here, the equilibrium 0 is obviously $\mathcal{O}$-stable, but it is $\mathcal{L}$-unstable both from below and from above.

Lyapunov stability and order stability in case of uniqueness

We show that $\mathcal{L}$-stability and $\mathcal{O}$-stability are equivalent concepts if we assume uniqueness in the future or in the past for solutions of (1.2). We need two preliminary results: the former concerns the validity of a comparison principle, the latter establishes a form of continuous dependence.

LEMMA 1.23. *Suppose* (C). *Assume that uniqueness in the past holds for solutions of* (1.2). *Let α be a lower solution and β be an upper solution of* (1.1) *on* $[a, b]$ *and suppose that $\alpha(a) < \beta(a)$. Then $\alpha \ll \beta$ on* $[a, b]$.

PROOF. We first show that $\alpha \leqslant \beta$. Notice that α and β are a lower solution and an upper solution for any initial value problem $x' = f(t, x)$, $x(a) = x_0$ with $\alpha(a) \leqslant x_0 \leqslant \beta(a)$. Hence, if we assume, by contradiction, that $\alpha \nleqslant \beta$, then Proposition 1.1 yields the existence of $t_0 \in\,]a, b]$ such that $\alpha(t_0) = \beta(t_0)$. Theorem 1.4 implies then that Eq. (1.1) has solutions x_1, x_2, with $x_1(a) = \alpha(a)$ and $x_2(a) = \beta(a)$, satisfying $\alpha \leqslant x_1 < x_2 \leqslant \beta$ on $[a, t_0]$ and hence $x_1(t_0) = x_2(t_0)$; thus contradicting uniqueness in the past for solutions of (1.2). We just proved that $\alpha < \beta$. Finally, by arguing as above, uniqueness in the past for solutions of (1.2) implies that $\alpha \ll \beta$ on $[a, b]$. □

REMARK 1.14. Assume that uniqueness in the past holds for solutions of (1.2). If α is a lower solution and u is a solution of (1.3), with $\alpha < u$, then $\alpha \ll u$. This implies that, if u is $\mathcal{O}$-stable from below, i.e. if there exists a sequence $(\alpha_n)_n$ of regular lower solutions of (1.3) such that $\alpha_n < u$ for every n and $\alpha_n \to u$ uniformly on $[0, T]$, then there is a subsequence $(\alpha_{n_k})_k$ of $(\alpha_n)_n$ such that $\alpha_{n_k} \ll \alpha_{n_{k+1}} \ll u$ for every k. Further we can see that proper $\mathcal{O}$-stability from below is equivalent to strict $\mathcal{O}$-stability from below.

LEMMA 1.24. *Suppose* (C). *Assume that uniqueness in the future holds for solutions of* (1.2). *Let z be a solution of* (1.1) *on* $[a, b]$. *Then for every* $\varepsilon > 0$ *there is* $\delta > 0$ *such that, for every* $t_0 \in [a, b[$ *and every* x_0, *with* $z(t_0) - \delta < x_0 < z(t_0)$, *any right-nonextendible solution x of* (1.2) *exists* (*at least*) *on* $[t_0, b]$ *and satisfies* $z - \varepsilon < x < z$ *on* $[t_0, b]$.

PROOF. We start with the following basically known statement (cf. [121]), which we prove for the sake of completeness.

CLAIM. *For every* $\varepsilon > 0$ *there is* $\delta > 0$ *such that every right-nonextendible solution x of* (1.1), *with* $z(a) - \delta < x(a) < z(a)$, *exists and satisfies* $z(t) - \varepsilon < x(t) \leqslant z(t)$ *on* $[a, b]$.

Assume by contradiction that there exists $\varepsilon > 0$ and a sequence $(x_n)_n$ of solutions of (1.1) on $[a, b_n]$, with $b_n < b$, such that $x_n(a) \to z(a)$, $z(t) - \varepsilon < x_n(t) < z(t)$ on $[a, b_n[$ and $x_n(b_n) = z(b_n) - \varepsilon$. We can assume that $(x_n(a))_n$ is strictly increasing and hence, by uniqueness in the future, $x_n < x_{n+1}$ on $[a, b_n]$. Therefore, $(b_n)_n$ is increasing, so that $b_n \to \bar{b} \in]a, b]$. Let x be a solution of (1.1), with $x(\bar{b}) = z(\bar{b}) - 2\varepsilon$, defined on $[\bar{b} - \eta, \bar{b}]$, for some $\eta > 0$. By uniqueness in the future, we have $x \leqslant x_n \leqslant z$ on $[\bar{b} - \eta, \bar{b}] \cap [a, b_n]$, for all large n. Hence any such a solution x_n can be continued to $\bar{b}$ and satisfies $z - \varepsilon \leqslant x_n \leqslant z$ on $[a, b_n[$ and $x \leqslant x_n \leqslant z$ on $[b_n, \bar{b}]$. Further, since the sequence $(x_n)_n$ is bounded, by the L^1-Carathéodory conditions, it is also equicontinuous on $[a, \bar{b}]$ and therefore, by monotonicity, it converges to some function y uniformly on $[a, \bar{b}]$. Since the convergence takes place in $W^{1,1}(0, T)$ as well, y is a solution of (1.1), which satisfies $y(a) = z(a)$, as $x_n(a) \to z(a)$. Accordingly, by uniqueness in the future, we conclude that $y = z$ on $[a, \bar{b}]$. On the other hand, as $x_n(b_n) = z(b_n) - \varepsilon \to z(\bar{b}) - \varepsilon$, and, by equicontinuity, $x_n(b_n) \to y(\bar{b})$, we get $y(\bar{b}) = z(\bar{b}) - \varepsilon$, which is a contradiction. Thus, the proof of the claim is finished.

Conclusion. Fix $\varepsilon > 0$ and, according to the Claim, for every $t_0 \in [a, b[$ let $\delta(t_0)$ be the supremum of all $\delta > 0$ such that every right-nonextendible solution x of (1.1), with $z(t_0) - \delta < x(t_0) < z(t_0)$, exists and satisfies $z(t) - \varepsilon < x(t) \leqslant z(t)$ on $[t_0, b]$. This lemma will be proved if we show that $\inf_{t_0 \in [a,b[} \delta(t_0) > 0$. Assume by contradiction that $\inf_{t_0 \in [a,b[} \delta(t_0) = 0$ and let $(t_n)_n$ be a sequence such that $\delta(t_n) \to 0$. We can assume that $(t_n)_n$ is increasing and converges to some $\bar{t} \in]a, b]$. If $(t_n)_n$ is decreasing, the proof is similar. Let $\bar{\delta} > 0$ be the constant associated with $\bar{t}$ by the Claim. We can find a solution $\bar{x}$ of (1.1), with $z(\bar{t}) - \bar{\delta} < \bar{x}(\bar{t}) < z(\bar{t})$, which exists on $[\bar{t} - \eta, b]$, for some $\eta > 0$, and satisfies $z - \varepsilon < \bar{x} < z$ on $[\bar{t} - \eta, b]$ and $\bar{x} \ll z$ on $[\bar{t} - \eta, \bar{t}]$. Then every right-nonextendible solution x of (1.1), with $\bar{x}(\bar{t} - \eta) < x(\bar{t} - \eta) < z(\bar{t} - \eta)$, exists and satisfies $\bar{x} < x < z$ and, hence, $z - \varepsilon < x < z$

on $[\bar{t}-\eta, b]$. This yields a contradiction as we have $\delta(t) \geqslant \min_{[\bar{t}-\eta,\bar{t}]}(z(t)-\bar{x}(t)) > 0$, for every $t \in [\bar{t}-\eta, \bar{t}]$. □

PROPOSITION 1.25. *Assume* (C). *Suppose that uniqueness in the past, or in the future, holds for solutions of* (1.2). *Then a solution u of* (1.3) *is $\mathcal{L}$-stable from below* (*respectively $\mathcal{L}$-stable from above, respectively $\mathcal{L}$-stable*) *if and only if it is $\mathcal{O}$-stable from below* (*respectively $\mathcal{O}$-stable from above, respectively $\mathcal{O}$-stable*).

PROOF. Let u be a solution of (1.3), which is $\mathcal{O}$-stable from below, and let $(\alpha_n)_n$ be a sequence of regular lower solutions of (1.3) such that $\alpha_n < u$ for every n and $\alpha_n \to u$ uniformly on $[0, T]$.

Case 1: *uniqueness in the past holds for* (1.2). By Lemma 1.23 and Remark 1.14, we can suppose that $\alpha_n \ll u$ for each n. Fix $\varepsilon > 0$ and pick n such that $\|\alpha_n - u\|_\infty < \varepsilon$. Set $\delta = \inf_{[0,T]}(u-\alpha_n) > 0$. Then for every $t_0 \in [0, T[$ and x_0 such that $\alpha_n(t_0) \leqslant u(t_0) - \delta < x_0 < u(t_0)$, any right-nonextendible solution x of (1.2) satisfies, according to Lemma 1.23, $\alpha_n \ll x \ll u$ on $[t_0, b]$ for any given $b > t_0$. Hence x exists and satisfies $u - \varepsilon < x < u$ on $[t_0, +\infty[$. This means that u is $\mathcal{L}$-stable from below.

Case 2: *uniqueness in the future holds for* (1.2). The conclusion is an immediate consequence of the following statement.

CLAIM. *Let α be a regular lower solution of* (1.3), *with $\alpha < u$, and set $\eta = \|\alpha - u\|_\infty$. Then there exists $\delta > 0$ such that for every $t_0 \in [0, T[$ every right-nonextendible solution x of* (1.2), *with $u(t_0) - \delta < x_0 < u(t_0)$, exists and satisfies $u - \eta < x < u$ on $[t_0, +\infty[$.*

If $\alpha \ll u$, then the result follows setting $\delta = \inf_{[0,T]}(u-\alpha) > 0$ and using Corollary 1.5. Therefore, suppose $\inf_{[0,T]}(u-\alpha) = 0$. Hence there exist points $t_1 \in [0, T]$ and $t_2 \in]t_1, t_1 + T[$ such that $\alpha(t_1) = u(t_1) - \eta$, $\lim_{t \to t_2^-} \alpha(t) = u(t_2)$ and $u(t) - \eta \leqslant \alpha(t) < u(t)$ on $[t_1, t_2[$. By Lemma 1.24, there is $\delta \in]0, \eta[$ such that, for every $t_0 \in [0, T[$, any right-nonextendible solution x of (1.2), with $u(t_0) - \delta < x_0 < u(t_0)$, exists and satisfies $u(t) - \eta < x(t) \leqslant u(t)$ on $[t_0, t_1 + T]$. Since $\alpha(t_1 + T) = u(t_1 + T) - \eta \leqslant x(t_1 + T) \leqslant u(t_1 + T)$ and α is a lower solution, x exists and satisfies $\alpha(t) \leqslant x(t) \leqslant u(t)$ on $[t_1 + T, t_2 + T[$ and $x(t) = u(t)$ on $[t_2 + T, +\infty[$. □

One-sided weak stability

The following definition of stability is a possible weakening of $\mathcal{L}$-stability suited to deal with cases where uniqueness of the solutions of (1.2) is not guaranteed (see [50]).

DEFINITION 1.17.

- We say that a solution u of (1.3) is *weakly stable* (briefly, *$\mathcal{W}$-stable*) *from below* if, for every $\varepsilon > 0$, there is a uniformly continuous function $\delta : [0, T[\to \mathbb{R}$, with $\delta > 0$, such that, for every $t_0 \in [0, T[$ and every x_0, with $u(t_0) - \delta(t_0) \leqslant x_0 \leqslant u(t_0)$, there exists a solution $x : [t_0, +\infty[\to \mathbb{R}$ of (1.2) which satisfies (1.15).
- If, further, (1.16) holds, we say that u is *$\mathcal{W}$-asymptotically stable from below*.
- *$\mathcal{W}$-stability* and *$\mathcal{W}$-asymptotic stability from above* are defined in a similar way.
- We say that a solution u of (1.3) is *$\mathcal{W}$-stable* if, for every $\varepsilon > 0$, there is a uniformly continuous function $\delta : [0, T[\to \mathbb{R}$, with $\delta > 0$, such that, for every $t_0 \in [0, T[$ and

every x_0, with $|x_0 - u(t_0)| \leqslant \delta(t_0)$, there exists a solution $x : [t_0, +\infty[\to \mathbb{R}$ of (1.2) *which satisfies* (1.17). *If, further,* (1.16) *holds, we say that u is $\mathcal{W}$-asymptotically stable.*

Order stability and weak stability
The notion of $\mathcal{W}$-stability is in any case equivalent to that of $\mathcal{O}$-stability.

PROPOSITION 1.26. *Assume* (C). *Let u be a solution of* (1.3). *Then u is $\mathcal{W}$-stable from below* (*respectively $\mathcal{W}$-stable from above, respectively $\mathcal{W}$-stable*) *if and only if it is $\mathcal{O}$-stable from below* (*respectively $\mathcal{O}$-stable from above, respectively $\mathcal{O}$-stable*).

PROOF. We only discuss stability from below. The proof is divided into two steps.

Step 1. Let u be a solution of (1.3), which is $\mathcal{O}$-stable from below, and let $(\alpha_n)_n$ be a sequence of regular lower solutions of (1.3) such that $\alpha_n < u$ for every n and $\alpha_n \to u$ uniformly on $[0, T]$. Fix $\varepsilon > 0$ and take n such that $\|\alpha_n - u\|_\infty < \varepsilon$. Then set $\delta = u - \alpha_n$ on $[0, T[$. Corollary 1.5 implies that, for every $t_0 \in [0, T]$ and every x_0, with $u(t_0) - \delta(t_0) \leqslant x_0 \leqslant u(t_0)$, there is a solution x which exists and satisfies $u - \varepsilon < x \leqslant u$ on $[t_0, +\infty[$.

Step 2. Let u be a solution of (1.3), which is $\mathcal{W}$-stable from below. If u is not isolated from below as a solution of (1.3), then it is obviously $\mathcal{O}$-stable. Accordingly, suppose that u is isolated from below. Let $\varepsilon > 0$ be such that there is no solution z of (1.3), satisfying $z < u$ and $\|z - u\|_\infty \leqslant \varepsilon$, and let δ be the function associated with ε. Since $\delta > 0$, there exists $t_0 \in [0, T[$ such that $\delta(t_0) > 0$. Fix a strictly increasing sequence $(x_0^{(n)})_n$ such that, for every n, $u(t_0) - \delta(t_0) < x_0^{(n)} < u(t_0)$ and $x_0^{(n)} \to u(t_0)$. Denote by $(x_n)_n$ the corresponding sequence of solutions of (1.2), satisfying, for every n, $x_n(t_0) = x_0^{(n)}$, $u - \varepsilon < x_n \leqslant u$ and $x_n < x_{n+1}$ on $[t_0, +\infty[$. Fix n and observe that $x_n(t_0 + T) > x_n(t_0)$. Indeed, otherwise $x_n|_{[t_0,t_0+T[}$ is a proper upper solution of (1.3) and hence, by Proposition 1.8, there exists a solution z of (1.3) such that $z < x_n$ on $[t_0, +\infty[$, $x_n(t) - z(t) \to 0$, as $t \to +\infty$, and hence $\|z - u\|_\infty \leqslant \varepsilon$, which is a contradiction. Therefore, denoting by α_n the T-periodic extension of $x_n|_{[t_0,t_0+T[}$ to $\mathbb{R}$, we conclude that $(\alpha_n)_n$ is a sequence of proper lower solutions of (1.3), satisfying, for every n, $\alpha_n < \alpha_{n+1} < u$ and $\alpha_n \to u$ uniformly on $[0, T]$. According to Proposition 1.20, we can construct a further sequence $(\bar{\alpha}_n)_n$ of proper regular lower solutions of (1.3) such that, for every n, $\bar{\alpha}_n < u$ and $\bar{\alpha}_n \to u$ uniformly on $[0, T]$. This implies that u is $\mathcal{O}$-stable from below. □

Stability via lower and upper solutions
We now come to the core of this section. In the following results we use lower and upper solutions to give a precise description of the stability properties of the T-periodic solutions of (1.1). In the next theorem we prove the stability of a one-sided isolated solution z of (1.3) in the presence of a lower solution below z, or of an upper solution above z.

THEOREM 1.27. *Assume* (C). *Let z be a solution of* (1.3).

(i) *If α is a proper lower solution of* (1.3) *such that $\alpha < z$ and there is no solution u of* (1.3) *satisfying $\alpha < u < z$, then z is $\mathcal{W}$-asymptotically stable from below.*
(ii) *If β is a proper upper solution of* (1.3) *such that $\beta > z$ and there is no solution u of* (1.3) *satisfying $z < u < \beta$, then z is $\mathcal{W}$-asymptotically stable from above.*

PROOF. We prove only the former statement. Since α is a proper lower solution, we know, by Proposition 1.21, that z is (properly) $\mathcal{O}$-stable from below, hence, by Proposition 1.26, z is $\mathcal{W}$-stable from below. The asymptotic $\mathcal{W}$-stability is then a consequence of Corollary 1.5 and Proposition 1.8. □

Conversely, Theorem 1.30 will show that instability occurs in all the other cases; it is based on the following two propositions.

PROPOSITION 1.28. *Assume* (C). *Let z be a solution of* (1.3).

(i) *If α is a proper lower solution of* (1.3) *such that $\alpha > z$ and there is no solution u of* (1.3) *satisfying $\alpha > u > z$, then z is $\mathcal{L}$-unstable from above.*

(ii) *If β is a proper upper solution of* (1.3) *such that $\beta < z$ and there is no solution u of* (1.3) *satisfying $z > u > \beta$, then z is $\mathcal{L}$-unstable from below.*

PROOF. We prove only the former statement. Let $t_0 \in [0, T]$ be such that $\alpha(t_0) > z(t_0)$. By Remark 1.9 there exists a solution $\widetilde{\alpha} :]-\infty, t_0] \to \mathbb{R}$ of (1.2), with $x_0 = \alpha(t_0)$, satisfying $z \leqslant \widetilde{\alpha} \leqslant \alpha$ on $]-\infty, t_0]$ and such that

$$\lim_{t \to -\infty} \bigl(\widetilde{\alpha}(t) - z(t)\bigr) = 0. \tag{1.18}$$

Set $\varepsilon = \alpha(t_0) - z(t_0) > 0$ and take any $\delta > 0$. By (1.18), there exists a positive integer n such that $z(t_0 - nT) \leqslant \widetilde{\alpha}(t_0 - nT) < z(t_0 - nT) + \delta$. Define, on $]-\infty, t_0 + nT]$, $x(t) = \widetilde{\alpha}(t - nT)$. Then x is a solution of (1.1) with $z(t_0) \leqslant x(t_0) < z(t_0) + \delta$ but $x(t_0 + nT) - z(t_0 + nT) = \varepsilon$. Hence we easily conclude that z is $\mathcal{L}$-unstable from above. □

PROPOSITION 1.29. *Assume* (C). *Let z be a solution of* (1.3).

(i) *If there exist a lower solution α of* (1.3) *and points t_1, t_2 such that $z(t_1) = \alpha(t_1)$ and $z(t_2) < \alpha(t_2)$, then z is $\mathcal{L}$-unstable from above.*

(ii) *If there exist an upper solution β of* (1.3) *and points t_1, t_2 such that $z(t_1) = \beta(t_1)$ and $z(t_2) > \beta(t_2)$, then z is $\mathcal{L}$-unstable from below.*

PROOF. We prove only the former statement. Assume without loss of generality that $t_1 < t_2$. By Proposition 1.8, we know that either every right-nonextendible solution $x : [t_1, \omega_+[\to \mathbb{R}$ of (1.2), with $t_0 = t_1$, $x_0 = \alpha(t_1) = z(t_1)$ and $x \geqslant \alpha$, is such that

$$\limsup_{t \to \omega_+} x(t) = +\infty,$$

or there exist the minimum solution $\widetilde{\alpha} : [t_1, +\infty[\to \mathbb{R}$ in $[\alpha, +\infty[$ of (1.2), with $t_0 = t_1$, $x_0 = \alpha(t_1) = z(t_1)$, and the minimum solution v in $[\alpha, +\infty[$ of (1.3), satisfying $v \geqslant \widetilde{\alpha}$ and

$$\lim_{t \to +\infty} \bigl(\widetilde{\alpha}(t) - v(t)\bigr) = 0.$$

Since there exists t_2 such that $\alpha(t_2) > z(t_2)$, we have $v \neq z$ and hence

$$\limsup_{t\to+\infty}\bigl(\widetilde{\alpha}(t) - z(t)\bigr) > 0.$$

In both cases we easily conclude that z is $\mathcal{L}$-unstable from above. □

THEOREM 1.30. *Assume* (C). *Let z be a solution of* (1.3).

- (i) *If there exists a lower solution α of* (1.3) *such that $z \not\geqslant \alpha$ and, in case $z < \alpha$, there is no solution u of* (1.3) *satisfying $z < u < \alpha$, then z is $\mathcal{L}$-unstable from above.*
- (ii) *If there exists an upper solution β of* (1.3) *such that $z \not\leqslant \beta$ and, in case $z > \beta$, there is no solution u of* (1.3) *satisfying $\beta < u < z$, then z is $\mathcal{L}$-unstable from below.*

PROOF. We prove only the former statement. Two cases may occur: either $\alpha > z$ or, by Proposition 1.6, there exist points t_1, t_2 such that $z(t_1) = \alpha(t_1)$ and $z(t_2) < \alpha(t_2)$. In the former case, the conclusion follows from Proposition 1.28, whereas in the latter it follows from Proposition 1.29. □

A direct consequence of the previous results is the following completion of Theorem 1.9, for what concerns the stability properties of solutions of (1.3) in the presence of a pair of lower and upper solutions.

THEOREM 1.31. *Assume* (C). *Suppose that α is a lower solution and β is an upper solution of* (1.3). *Denote by v and w the minimum and the maximum solutions in* $[\min\{\alpha,\beta\}, \max\{\alpha,\beta\}]$ *of* (1.3).

- (i) *If $\alpha < \beta$, then v is $\mathcal{W}$-asymptotically stable from below, provided α is a proper lower solution, and w is $\mathcal{W}$-asymptotically stable from above, provided β is a proper upper solution.*
- (ii) *If $\alpha > \beta$, then v is $\mathcal{L}$-unstable from below, provided β is a proper upper solution, and w is $\mathcal{L}$-unstable from above, provided α is a proper lower solution.*
- (iii) *If $\alpha \not\leqslant \beta$ and $\beta \not\leqslant \alpha$, then every solution u of* (1.3) *satisfying $v \leqslant u \leqslant w$ is $\mathcal{L}$-unstable from below and from above.*

PROOF. In case (i) the conclusion follows from Theorem 1.27. In case (ii) the conclusion follows from Proposition 1.28. In case (iii), if u is a solution of (1.3) satisfying $\min\{\alpha,\beta\} \leqslant v \leqslant u \leqslant w \leqslant \max\{\alpha,\beta\}$, then according to Proposition 1.6, there exist points t_1 and t_2 such that $\alpha(t_1) = \beta(t_1) = u(t_1)$ and either $\beta(t_2) < u(t_2)$, or $u(t_2) < \alpha(t_2)$. The instability of u then follows from Proposition 1.29. □

REMARK 1.15. In case (i), from Proposition 1.8 we further deduce the following invariance and attractivity result. For every t_0, every solution $x : [t_0, +\infty[\to \mathbb{R}$ of (1.1) is such that: if $\alpha \leqslant x \leqslant \beta$ then $\widetilde{\alpha} \leqslant x \leqslant \widetilde{\beta}$, if $\alpha \leqslant x \leqslant v$ then $\lim_{t\to+\infty}(v(t) - x(t)) = 0$, if $w \leqslant x \leqslant \beta$ then $\lim_{t\to+\infty}(x(t) - w(t)) = 0$.

From Propositions 1.18, 1.25, 1.26 and Remark 1.14 we immediately get the following result.

COROLLARY 1.32. *Assume* (C). *Suppose that α is a proper lower solution, β is a proper upper solution of* (1.3) *and $\alpha < \beta$. Denote by v and w the minimum and the maximum solutions in* $[\alpha, \beta]$ *of* (1.3). *Suppose further that either uniqueness in the past for solutions of* (1.2) *holds, or uniqueness in the future for solutions of* (1.2) *holds and α and β are strict. Then v is $\mathcal{L}$-asymptotically stable from below and w is $\mathcal{L}$-asymptotically stable from above.*

Continua of stable or unstable T-periodic solutions

Theorem 1.31 describes the stability properties of the minimum and the maximum solutions v and w of (1.3) wedged between a given pair of lower and upper solutions. Now, we turn to investigate the behaviour of the solutions between v and w. We start by specifying statement (i) in Theorem 1.31. Namely, we prove the existence of a totally ordered continuum of (two-sided) $\mathcal{W}$-stable T-periodic solutions lying between a pair of lower and upper solutions ordered in the standard way, i.e. the lower solution is below the upper solution.

THEOREM 1.33. *Assume* (C). *Suppose that α is a proper lower solution and β is a proper upper solution of* (1.3), *satisfying $\alpha < \beta$, and denote by v and w respectively the minimum and the maximum solution of* (1.3) *in* $[\alpha, \beta]$. *Then there exists a totally ordered continuum $\mathcal{K}$ in* $C^0([0, T])$, *such that every $u \in \mathcal{K}$ is an $\mathcal{O}$-stable solution of* (1.3) *satisfying $v \leqslant u \leqslant w$; further, $u_1 = \min \mathcal{K}$ is properly $\mathcal{O}$-stable from below and $u_2 = \max \mathcal{K}$ is properly $\mathcal{O}$-stable from above.*

PROOF. Let us denote by $\mathcal{S}_1$ the set of all solutions u of (1.3), with $\alpha < u < \beta$, which are properly $\mathcal{O}$-stable from below. Since, by Proposition 1.21, the minimum solution v is properly $\mathcal{O}$-stable from below, $\mathcal{S}_1$ is non-empty. Notice also that, since $\mathcal{S}_1$ is bounded in $C^0([0, T])$, the L^1-Carathéodory conditions imply that it is also equicontinuous and hence relatively compact in $C^0([0, T])$.

Let us show that the set $(\mathcal{S}_1, \leqslant)$ is inductively ordered. Let $\mathcal{T}$ be a totally ordered subset of $\mathcal{S}_1$. Since $\mathcal{T}$ is uniformly bounded from above, by Lemma 1.15 there exists a maximal solution $\hat{w}$ of (1.3) in the C^0-closure $\bar{\mathcal{T}}$ of $\mathcal{T}$. Actually $\hat{w} \in \mathcal{T}$. Indeed, let $(w_n)_n$ be an increasing sequence in $\mathcal{T}$ converging to $\hat{w}$ in $C^0([0, T])$; since each w_n is properly $\mathcal{O}$-stable from below, by a diagonal argument we conclude that $\hat{w}$ as well is properly $\mathcal{O}$-stable from below. Hence any totally ordered subset of $\mathcal{S}_1$ has an upper bound in $\mathcal{S}_1$. By Zorn Lemma, there exists a maximal element $u_1 \in \mathcal{S}_1$.

Let us denote by $\mathcal{S}_2$ the set of all solutions u of (1.3), with $u_1 \leqslant u < \beta$, which are properly $\mathcal{O}$-stable from above. Since the maximum solution w is properly $\mathcal{O}$-stable from above, $\mathcal{S}_2$ is non-empty. Arguing as above, we see that there exists a minimal solution $u_2 \in \mathcal{S}_2$.

If $u_1 = u_2$, the conclusion is achieved. Therefore, let us suppose that $u_1 < u_2$ and let us denote by $\mathcal{S}_3$ the set of all solutions u of (1.3), with $u_1 \leqslant u \leqslant u_2$. Notice that $\mathcal{S}_3$ is compact in $C^0([0, T])$.

Let us observe that there is no proper lower solution and no proper upper solution of (1.3) between u_1 and u_2. Indeed, if we assume that there exists, for instance, a proper lower solution α^*, with $u_1 < \alpha^* < u_2$, and we denote by z the minimum solution of (1.3), with

$\alpha^* < z \leqslant u_2$, Proposition 1.21 implies that z is properly $\mathcal{O}$-stable from below, thus contradicting the maximality of u_1.

Next, we prove that if $z_1, z_2 \in \mathcal{S}_3$, with $z_1 < z_2$, then there exists a solution z_3 of (1.3) such that $z_1 < z_3 < z_2$. Indeed, if we assume that there is no solution z of (1.3), with $z_1 < z < z_2$, then any nonextendible solution x of (1.1), with $z_1 < x < z_2$, is either a proper lower solution or a proper upper solution, thus contradicting our preceding conclusion. Hence $\mathcal{S}_3$ is dense-in-itself with respect to the order.

Now, let us fix a solution $u_0 \in \mathcal{S}_3$ and denote by $\mathcal{S}(u_0)$ a maximal totally ordered subset of $\mathcal{S}_3$ with $u_0 \in \mathcal{S}(u_0)$. As $u_1, u_2 \in \mathcal{S}(u_0)$, this set is nondegenerate. By Lemma 1.3, $\mathcal{S}(u_0)$ is homeomorphic to a compact interval of $\mathbb{R}$, so it is connected.

Finally, it is clear that every $u \in \mathcal{S}(u_0)$ is $\mathcal{O}$-stable and $u_1 = \min \mathcal{S}(u_0)$ and $u_2 = \max \mathcal{S}(u_0)$ are properly $\mathcal{O}$-stable from below and above, respectively. Therefore, we can set $\mathcal{K} = \mathcal{S}(u_0)$. □

REMARK 1.16. The set $\mathcal{S}_3$, defined in the proof of Theorem 1.33, is obviously connected too. Indeed, for each $u_0 \in \mathcal{S}_3$, the set $\mathcal{S}(u_0)$ is connected. Since $u_1, u_2 \in \bigcap_{u_0 \in \mathcal{S}_3} \mathcal{S}(u_0)$, the set $\mathcal{S}_3 = \bigcup_{u_0 \in \mathcal{S}_3} \mathcal{S}(u_0)$ is connected.

REMARK 1.17. We notice that if α is a lower solution and β is an upper solution of (1.3), with $\alpha > \beta$, then one cannot generally guarantee the existence in between of a solution of (1.3) which is $\mathcal{L}$-unstable both from below and from above. A simple example is given by (1.3), with $f(x) = x|\sin(1/x)|$ for $x \neq 0$ and $f(x) = 0$ for $x = 0$. Here, $\beta = -1$ is a strict upper solution and $\alpha = 1$ is a strict lower solution; in between there is a countable set of equilibria, none of which is simultaneously $\mathcal{L}$-unstable from below and from above. Of course, according to Theorem 1.31, there are equilibria which are $\mathcal{L}$-unstable either from below or from above.

Finally, we consider the case where α and β are not comparable. A counterpart of Theorem 1.33, which specifies statement (iii) in Theorem 1.31, is based on the following preliminary result.

LEMMA 1.34. *Assume* (C). *Let v, w be solutions of* (1.3), *such that $v \neq w$ and $v(t_0) = w(t_0)$ for some t_0. Then the set*

$$\mathcal{K} = \bigl\{u : [t_0, t_0 + T] \to \mathbb{R} \mid u \text{ is a solution of (1.1) with } \min\{v, w\} \leqslant u \leqslant \max\{v, w\}\bigr\}$$

is a nondegenerate continuum in $C^0([t_0, t_0 + T])$ and every $u \in \mathcal{K}$, extended by T-periodicity onto $\mathbb{R}$, is a $\mathcal{L}$-unstable solution of (1.3).

PROOF. Every solution u of (1.1), with $\min\{v, w\} \leqslant u \leqslant \max\{v, w\}$ on $[t_0, t_0 + T]$, extended by T-periodicity onto $\mathbb{R}$, is a solution of (1.3). Since $\min\{v, w\}$ and $\max\{v, w\}$ are solutions of (1.2), with $x_0 = v(t_0) = w(t_0)$, Theorem 1.4 guarantees that the set $\mathcal{K}$ is a continuum in $C^0([t_0, t_0 + T])$. The instability finally follows from Proposition 1.29. □

THEOREM 1.35. *Assume* (C). *Suppose that* α *is a lower solution and* β *is an upper solution of* (1.3), *with* $\alpha \nleqslant \beta$ *and* $\alpha \ngeqslant \beta$. *Then the set*

$$\mathcal{K} = \{u \mid u \text{ is a solution of } (1.3) \text{ with } \min\{\alpha, \beta\} \leqslant u \leqslant \max\{\alpha, \beta\}\}$$

is a continuum in $C^0([0, T])$ *and every* $u \in \mathcal{K}$ *is* $\mathcal{L}$*-unstable.*

Complicated dynamics

In the frame of Lemma 1.34, the existence of a nondegenerate continuum entails fairly complicated dynamics for the solutions of (1.1) between $\min\{v, w\}$ and $\max\{v, w\}$. In particular, there exist homoclinics, subharmonics of any order and almost periodic solutions, which are not periodic of any fixed period; this last assertion will now be proved.

THEOREM 1.36. *Assume* (C). *Let* v, w *be solutions of* (1.3) *such that* $v \neq w$ *and* $v(t_0) = w(t_0)$ *for some* t_0. *Then there exists a* (*Čech–Lebesgue*) *infinite dimensional set* $\mathcal{X} \subseteq L^\infty(\mathbb{R})$ *such that every* $x \in \mathcal{X}$ *is a* (*Bohr*) *almost periodic solution of* (1.1), *with* $\min\{v, w\} < x < \max\{v, w\}$, *which is not periodic of any fixed period.*

PROOF. Possibly replacing v with $\min\{v, w\}$ and w with $\max\{v, w\}$, we can assume $v < w$ and $v(t_0) = w(t_0)$ for some t_0. It is not even restrictive to suppose $t_0 = 0$. Let $\mathcal{K} \subseteq C^0([0, T])$ be the set of all solutions x of (1.3) with $v \leqslant x \leqslant w$. By Lemma 1.34, $\mathcal{K}$ is a nondegenerate continuum and it is dense-in-itself with respect to the order (see also Proposition 1.13).

Step 1. *Existence of almost periodic solutions.* Without loss of generality we may assume $T = 1$. Fix a sequence $(u_n)_n$ of solutions of (1.3) such that $v \leqslant u_n \leqslant w$ and

$$0 < \|u_{n+\nu} - u_n\|_\infty < 2^{-n} \tag{1.19}$$

for every $n \in \mathbb{N}$ and $\nu \in \mathbb{N}^+$. Hence $(u_n)_n$ uniformly converges to a solution u_∞ of (1.3), with $v \leqslant u_\infty \leqslant w$. Let us define a function $x : \mathbb{R} \to \mathbb{R}$ by setting $x(t) = u_\infty(t)$ on $[0, 1[$ and, for each $n \in \mathbb{N}$ and $k \in \mathbb{Z}$, $x(t) = u_n(t)$ on $[(2k + 1)2^n, (2k + 1)2^n + 1[$. The function x is well-defined, since every $m \in \mathbb{Z} \setminus \{0\}$ can be represented in a unique way as $m = (2k + 1)2^n$ for some $k \in \mathbb{Z}$ and $n \in \mathbb{N}$. Moreover, since $u_n(0) = u_\infty(0)$ for each n, x is a solution of (1.1).

We want to prove that x is almost periodic and it is not periodic of any fixed period. Let us recall that a continuous function $x : \mathbb{R} \to \mathbb{R}$ is almost periodic if, for every $\varepsilon > 0$, there exists $l > 0$ such that, for every t_0, there is $\tau \in [t_0, t_0 + l]$ with $|x(t + \tau) - x(t)| < \varepsilon$ on $\mathbb{R}$.

Fix $\varepsilon > 0$ and pick $n \in \mathbb{N}^+$ such that

$$2^{-n} < \varepsilon \tag{1.20}$$

and

$$\|u_j - u_\infty\|_\infty < \varepsilon \tag{1.21}$$

for all $j \geqslant n$. Set $l = 2^{n+2}$ and take $t_0 \in \mathbb{R}$. Let $k \in \mathbb{Z}$ be such that $(2k-1)2^n < t_0 \leqslant (2k+1)2^n$. Accordingly, set $\tau = (2k+1)2^n$ and note that $\tau \in [t_0, t_0 + 2^{n+1}[\subseteq [t_0, t_0 + l]$. We want to prove that, for every t, $|x(t+\tau) - x(t)| < \varepsilon$.

Let $t \in [0, 1[$ and hence $t + \tau \in [(2k+1)2^n, (2k+1)2^n + 1[$. We have, by (1.21),

$$\left|x(t+\tau) - x(t)\right| = \left|u_n(t) - u_\infty(t)\right| < \varepsilon.$$

Let $t \in [(2j+1)2^p, (2j+1)2^p + 1[$, for some $j \in \mathbb{Z}$ and $p \in \mathbb{N}$, and hence $t + \tau \in [(2j+1)2^p + (2k+1)2^n, (2j+1)2^p + (2k+1)2^n + 1[$. In order to estimate $x(t+\tau) - x(t)$, we distinguish three cases.

- Let $p < n$. Then there exists $r \in \mathbb{N}$ such that $p + 1 + r = n$ and $(2j+1)2^p + (2k+1)2^n = (2j+1)2^p + (2k+1)2^{p+1+r} = (2(j + (2k+1)2^r) + 1)2^p$. Hence we have $x(t+\tau) = u_p(t) = x(t)$.
- Let $p > n$. Then there exists $r \in \mathbb{N}$ such that $n + 1 + r = p$ and $(2j+1)2^p + (2k+1)2^n = (2j+1)2^{n+r+1} + (2k+1)2^n = (2(k + (2j+1)2^r) + 1)2^n$. Hence, by (1.19) and (1.20), we have $x(t+\tau) = u_n(t)$ and

$$\left|x(t+\tau) - x(t)\right| = \left|u_n(t) - u_p(t)\right| < 2^{-n} < \varepsilon.$$

- Let $p = n$. Then we have $(2j+1)2^p + (2k+1)2^n = (j+k+1)2^{p+1}$. If $j+k+1 = 0$, then $t + \tau \in [0, 1[$ and, by (1.20) and (1.21),

$$\left|x(t+\tau) - x(t)\right| = \left|u_\infty(t) - u_p(t)\right| = \left|u_\infty(t) - u_n(t)\right| < \varepsilon.$$

If $j + k + 1 \neq 0$, then there exist $r \in \mathbb{N}$ and $h \in \mathbb{Z}$ such that $j + k + 1 = (2h+1)2^r$; hence $(j+k+1)2^{p+1} = (2h+1)2^{p+r+1}$. Accordingly, by (1.19) and (1.20), we get

$$\left|x(t+\tau) - x(t)\right| = \left|u_{p+r+1}(t) - u_p(t)\right| = \left|u_{n+r+1}(t) - u_n(t)\right| < 2^{-n} < \varepsilon.$$

Finally, we prove that x is not T-periodic for any $T > 0$. We first recall that, for each $n \in \mathbb{N}$, $x = u_n$ on $[2^n, 2^n + 1]$ and $x = u_{n+1}$ on $[2^{n+1}, 2^{n+1} + 1]$. Since $u_n \neq u_{n+1}$, x is not T-periodic for any $T \in \mathbb{Q}^+$. Assume by contradiction that x is T-periodic for some $T \in \mathbb{R}^+ \setminus \mathbb{Q}$. For each $n \in \mathbb{Z}$, we have $x(n) = x(0)$, by construction, and $x(n + mT) = x(0)$ for every $m \in \mathbb{Z}$, by T-periodicity. Using the density in $\mathbb{R}$ of the set $\{n + mT \mid n, m \in \mathbb{Z}\}$ and the continuity of x, we conclude that x is constant, which is a contradiction.

Step 2. *Existence of an infinite dimensional set of almost periodic solutions.* Fix a sequence $(z_n)_n$ of solutions of (1.3) satisfying $v < z_{n+1} < z_n < w$ and $\|z_n - z_{n+\nu}\|_\infty < 2^{-n}$ for every $n, \nu \in \mathbb{N}$. For each n, let $\mathcal{S}_n$ be the set of all solutions u of (1.3) such that $z_{2n+1} \leqslant u \leqslant z_{2n}$. By Lemma 1.34, $\mathcal{S}_n \subseteq C^0([0, T])$ is compact and dense-in-itself with respect to the order. Hence Lemma 1.3 implies that there exists a continuum $\mathcal{T}_n \subseteq \mathcal{S}_n$ which is homeomorphic to $[0, 1]$. For any sequence $(u_n)_n \in \prod_{n=0}^{+\infty} \mathcal{T}_n$ denote by $\Phi((u_n)_n)$ the almost periodic solution x of (1.1) constructed in Step 1 and set $\mathcal{X} = \Phi\big(\prod_{n=0}^{+\infty} \mathcal{T}_n\big)$. Fix a sequence $(\hat{u}_n)_n \in \prod_{n=0}^{+\infty} \mathcal{T}_n$ and let N be any positive integer. The map $\Phi_N : \prod_{n=0}^{N-1} \mathcal{T}_n \to L^\infty(\mathbb{R})$ defined by setting $\Phi_N(u_0, u_1, \ldots, u_{N-1}) = \Phi(u_0, u_1, \ldots, u_{N-1}, \hat{u}_N, \hat{u}_{N+1}, \ldots)$ is one-to-one and continuous, once $\prod_{n=0}^{N-1} \mathcal{T}_n$ is endowed with the product topology. Actually, since

$\prod_{n=0}^{N-1} \mathcal{T}_n$ is compact, Φ_N is a homeomorphism between $\prod_{n=0}^{N-1} \mathcal{T}_n$ and $\Phi_N(\prod_{n=0}^{N-1} \mathcal{T}_n) = \mathcal{X}_N$. Since $\mathcal{X}_N \subseteq \mathcal{X}$ and $\dim \mathcal{X}_N = N$, we conclude that $\dim \mathcal{X} = +\infty$ (see [47, Chapter 7]). □

EXAMPLE 1.4. We consider once more equation (1.12). Let $\alpha : [-\frac{1}{2}, \frac{1}{2}[\to \mathbb{R}$ be defined by $\alpha(t) = (\frac{\sqrt{2}-1}{4} t)^2$ on $[-\frac{1}{2}, 0]$, and $\alpha(t) = (\frac{1}{4}t)^2$ on $]0, \frac{1}{2}[$. Then α is a solution of (1.12) and a proper lower solution of the associated 1-periodic problem. Note that $\beta = 0$ is a proper upper solution of the 1-periodic problem. By Theorem 1.9, there exists a 1-periodic solution w of (1.12) such that $0 < w < \alpha$ and $w(0) = 0$. Observe that, by symmetry, if x is a solution of (1.12), then $y(t) = -x(-t)$ is also a solution of (1.12). Hence the function $v(t) = -w(-t)$ is a 1-periodic solution of (1.12) such that $v < 0$ and $v(0) = 0$. Applying Lemma 1.34 we see that the set $\mathcal{K}$ of all solutions $u : [0, 1] \to \mathbb{R}$ of (1.12), with $v \leqslant u \leqslant w$, is a nondegenerate continuum in $C^0([0, 1])$ and every $u \in \mathcal{K}$ is a $\mathcal{L}$-unstable 1-periodic solution of (1.12). In addition, we can see that $v(t) < 0 < w(t)$ on $]0, 1[$ and the continuum $\mathcal{K}$ is totally ordered. Indeed, by a result in [29, Corollary 3.5], uniqueness for the Cauchy problem associated with Eq. (1.12) is guaranteed for any t_0, x_0 with $(t_0, x_0) \neq (0, 0)$. Hence, if $u_1, u_2 \in \mathcal{K}$, we have $u_1(t) = u_2(t)$ if and only if $t \in \mathbb{Z}$; the 1-periodicity of u_1 and u_2 yields either $u_1 < u_2$ or $u_2 < u_1$. By Theorem 1.36 there exists an infinite dimensional set $\mathcal{X} \subseteq L^\infty(\mathbb{R})$ such that every $x \in \mathcal{X}$ is an almost periodic solution of (1.12), with $v < x < w$, and x is not periodic of any fixed period. Furthermore, there exist periodic solutions x of (1.12), with $v < x < w$, that are subharmonics of any order. To verify this let $p_1, p_2, \dots, p_n$ be two by two distinct numbers such that $v(\frac{1}{2}) \leqslant p_i \leqslant w(\frac{1}{2})$ for $i = 1, \dots, n$. Let $u_i \in \mathcal{K}$ be such that $u_i(\frac{1}{2}) = p_i$. Define $x(t) = u_i(t)$ on $[i - 1, i[$, for $i = 1, \dots, n$, and extend x by n-periodicity to $\mathbb{R}$. Then x is an n-periodic solution of (1.12). Clearly, x is not k-periodic for any positive integer $k < n$. Suppose by contradiction that x is T-periodic, for some non-integer $T < n$. Then $x(T) = x(0) = 0$ and $x'(T) = x'(0) = 0$, while $x'(T) = \sqrt{|x(T)|} + h(T) = h(T) < 0$. Finally, we observe that homoclinic solutions of (1.12) can be trivially constructed as well.

REMARK 1.18. The solution set of (1.3) is the union of a family of mutually ordered connected components in $C^0([0, T])$. Yet, unlike the case where the property of uniqueness holds for (1.2) and hence nondegenerate continua are necessarily one-dimensional, such components may have arbitrarily large dimension (see [114]). We have seen that the dynamics of the trajectories of (1.1), which lie in the plane region filled by the graphs of the T-periodic solutions in a given connected component, may be quite complicated. Therefore any attempt to get a global qualitative portrait of solutions of (1.1) appears at least awkward, if solutions having graph in such regions are included in the analysis. Instead, it seems more meaningful to study only the dynamics of the solutions whose graph lies outside. In the light of Theorem 1.10, the qualitative behaviour of these solutions closely resembles the case where uniqueness holds. Then one could be naturally lead to look at the connected components of the set of solutions of (1.3) as single objects and to discuss the stability of each of them, by checking the stability from below of its minimum element and the stability from above of its maximum element, whenever they exist. Of course the consideration of a multivalued Poincaré operator would play a role here.

1.7. *Asymptotic behaviour of bounded solutions*

We already noticed in Section 1.4 that the existence of a solution u of (1.3) is always guaranteed in the presence of a bounded solution x of (1.1) defined on an unbounded interval. In this section we make this statement more precise, providing a complete extension of the Massera Convergence Theorem to the case where the uniqueness assumption for solutions of (1.2) is dropped. Namely, we see that either x converges to u, or the set of all solutions u of (1.3), whose range contains ω-limit points of x, forms a nondegenerate closed connected set in $C^0([0,T])$.

Lack of T-monotonicity and continua of T-periodic solutions

We start with a technical lemma saying that if a solution x of (1.1) and a solution v of (1.3) attain the same values at two points $a < b$, then there is a nondegenerate closed connected set of solutions u of (1.3) whose graphs completely fill the graph of x on $[a,b]$.

LEMMA 1.37. *Assume* (C). *Let v be a solution of* (1.3) *and $x:[a,b]\to\mathbb{R}$ a solution of* (1.1). *Suppose that $x(a)=v(a)$, $x(b)=v(b)$ and $x(t)>v(t)$ on $]a,b[$. Then the set $\mathcal{C}$ of all solutions $u\geqslant v$ of* (1.3) *such that there exists $t_0\in[a,b]$ with $u(t_0)=x(t_0)$ is a nondegenerate closed connected subset of $C^0([0,T])$. Furthermore, for each $t_0\in[a,b]$ there exists $u\in\mathcal{C}$ with $u(t_0)=x(t_0)$.*

PROOF. The set $\mathcal{C}$ is clearly closed and non-empty.

Step 1. Let us prove that $\mathcal{C}$ is dense-in-itself with respect to the order. Indeed, let $u_1,u_2\in\mathcal{C}$ be such that $u_1<u_2$. If $u_1(t_0)=u_2(t_0)$ for some t_0, then Lemma 1.34 yields the existence of a solution u of (1.3) with $u_1<u<u_2$. Clearly, $u\in\mathcal{C}$. If $u_1\ll u_2$ and no solution u of (1.3) exists with $u_1<u<u_2$, we set $\hat{x}=x$ on $[a,b]$ and $\hat{x}=v$ on $\mathbb{R}\setminus[a,b]$, $y=\min\{\max\{\hat{x},u_1\},u_2\}$. Then y is a nonextendible solution of (1.1) such that $u_1<y<u_2$ and $\lim_{t\to-\infty}(y(t)-u_1(t))=\lim_{t\to+\infty}(y(t)-u_1(t))=0$, contradicting the conclusions of Theorem 1.14. Hence there is a solution u of (1.3) such that $u_1<u<u_2$. Clearly, $u\in\mathcal{C}$.

Step 2. Let us prove that $\mathcal{C}$ is not a singleton. We distinguish two cases.

- Let $b-a\leqslant T$. Consider the function $w:[a,a+T]\to\mathbb{R}$ defined by $w(t)=x(t)$ on $[a,b]$ and $w(t)=v(t)$ on $[b,a+T]$, and extend w by T-periodicity onto $\mathbb{R}$. Then both v and w belong to $\mathcal{C}$.
- Let $b-a>T$. We show that v is not isolated from above in the set of all solutions of (1.3). Indeed, if v were the maximum solution of (1.3), then the function $\hat{x}:\mathbb{R}\to\mathbb{R}$ defined by $\hat{x}(t)=x(t)$ on $[a,b]$ and $\hat{x}(t)=v(t)$ on $\mathbb{R}\setminus[a,b]$ would be a solution of (1.1) contradicting the conclusions of Theorem 1.17. Whereas, if w were a solution of (1.3) with $v\ll w$ and such that there is no solution u of (1.3) with $v<u<w$, then the function $\hat{x}:\mathbb{R}\to\mathbb{R}$ defined by $\hat{x}(t)=\min\{x(t),w(t)\}$ on $[a,b]$ and $\hat{x}(t)=v(t)$ on $\mathbb{R}\setminus[a,b]$ would be a solution of (1.1) contradicting the conclusions of Lemma 1.14. Hence there exists a sequence $(u_n)_n$ of solutions of (1.3), with $u_n>v$ for every n, which converges uniformly to v. Then $u_n\in\mathcal{C}$ for all large n.

Step 3. Let us prove that $\mathcal{C}$ is connected. Pick $w\in\mathcal{C}$, with $w>v$. Set $\mathcal{K}=\{u\mid u$ is a solution of (1.3) with $v\leqslant u\leqslant w\}$. Notice that $\mathcal{K}\subseteq\mathcal{C}$, $\mathcal{K}$ is compact and, by Step 1, dense-in-itself with respect to the order. Let $\mathcal{T}\subseteq\mathcal{K}$ be a maximal totally ordered subset of $\mathcal{K}$ and notice that both v and w belong to $\mathcal{T}$. By Lemma 1.3, $\mathcal{T}$ is homeomorphic to a compact interval of $\mathbb{R}$. This shows that any pair $w_1, w_2 \in \mathcal{C}$ can be connected by a continuum (in fact an arc) containing v and contained in $\mathcal{C}$.

Step 4. Let us prove that for each $t_0 \in [a,b]$ there exists $u \in \mathcal{C}$ with $u(t_0) = x(t_0)$. We distinguish two cases again.

- If $b - a \leqslant T$, the conclusion follows arguing as in Step 2.
- If $b - a > T$, we prove that for each $t_0 \in [a,b]$ there exists $u \in \mathcal{C}$ with $u(t_0) \geqslant x(t_0)$.

As $\mathcal{C}$ is connected the conclusion will follow. Accordingly, let us suppose by contradiction there is a point $t_0 \in [a,b]$ such that $u(t_0) < x(t_0)$ for all $u \in \mathcal{C}$. Assume first that $\mathcal{C}$ is bounded. Then $\mathcal{C}$ is a continuum. Let $\mathcal{T}$ be a nondegenerate maximal totally ordered subset of $\mathcal{C}$. Since $\mathcal{C}$ is dense-in-itself, by Lemma 1.3, $\mathcal{T}$ is homeomorphic to a compact interval. Set $w = \max \mathcal{T}$. There are points a_1, b_1 such that $a \leqslant a_1 < t_0 < b_1 \leqslant b$, $x(a_1) = w(a_1)$, $x(b_1) = w(b_1)$ and $x(t) > w(t)$ on $]a_1, b_1[$. By Step 2 there exist a solution u of (1.3), with $u > w$, and a point $t_1 \in [a_1, b_1]$ such that $u(t_1) = x(t_1)$. Hence we conclude that $u \in \mathcal{C}$ and $u > w$, thus contradicting the maximality of w. Assume now that $\mathcal{C}$ is unbounded from above and let $u \in \mathcal{C}$ be such that $\max u > \max x$. Since $u(t_0) < x(t_0)$, there are points a_1, b_1, with $a_1 < t_0 < b_1 < a_1 + T$, such that $x(a_1) = u(a_1)$, $x(b_1) = u(b_1)$ and $x(t) > u(t)$ on $]a_1, b_1[$. Since $b_1 - a_1 < T$, a contradiction is obtained, arguing as in Step 2. □

Next, we specify Corollary 1.11 by showing that existence of solutions of (1.1) which are not T-monotone yields existence of nondegenerate continua of solutions of (1.3).

PROPOSITION 1.38. *Assume* (C). *Let* $x :]\omega_-, \omega_+[\to \mathbb{R}$ *be a nonextendible solution of* (1.1) *and suppose that* x *is not* T*-monotone. Then there exists a nondegenerate continuum* $\mathcal{K}$ *of solutions of* (1.3) *such that, for every* $u \in \mathcal{K}$, *there is* $t_0 \in]\omega_-, \omega_+[$ *with* $u(t_0) = x(t_0)$.

PROOF. We proceed in two steps.

Step 1. Assume either $\omega_- = -\infty$, or $\omega_+ = +\infty$. We know from the first two steps in the proof of Theorem 1.10 that there are points t_1, t_2, p_1, p_2, with $p_1 < p_2$, such that, for every $p \in]p_1, p_2[$, there are a lower solution α and an upper solution β of (1.3) such that $\alpha(t_1) = \beta(t_1) = x(t_1)$ and $\alpha(t_2) = \beta(t_2) = p$. Then Theorem 1.9 and Lemma 1.34 yield the existence of a nondegenerate continuum $\mathcal{K}$ satisfying the required conditions.

Step 2. Assume $\omega_+, \omega_- \in \mathbb{R}$, with $\omega_+ - \omega_- > T$. We distinguish two cases.

- Suppose that

$$\lim_{t \to \omega_-} x(t) = \lim_{t \to \omega_+} x(t) = -\infty;$$

the case where $\lim_{t \to \omega_-} x(t) = \lim_{t \to \omega_+} x(t) = +\infty$ being treated similarly. Since x is not T-monotone, Theorem 1.10 implies the existence of a solution v of (1.3) such that $x(t_0) > v(t_0)$ for some $t_0 \in]\omega_-, \omega_+[$. Hence we can find $a, b \in]\omega_-, \omega_+[$, with $a < b$, such that $x(a) = v(a)$, $x(b) = v(b)$ and $x(t) > v(t)$ on $]a, b[$. Lemma 1.37 yields the existence of a nondegenerate continuum $\mathcal{K}$ having the desired properties.

- Suppose that

$$\lim_{t \to \omega_-} x(t) = -\infty \quad \text{and} \quad \lim_{t \to \omega_+} x(t) = +\infty;$$

the case where $\lim_{t\to\omega_-} x(t) = +\infty$ and $\lim_{t\to\omega_+} x(t) = -\infty$ being treated similarly. Set $\varphi(t) = x(t+T) - x(t)$ on $]\omega_-, \omega_+ - T[$. We have $\lim_{t\to\omega_-} \varphi(t) = \lim_{t\to\omega_+ - T} \varphi(t) = +\infty$ and, as x is not T-monotone, $\varphi(t_0) = x(t_0 + T) - x(t_0) < 0$ for some $t_0 \in\,]\omega_-, \omega_+ - T[$. Define

$$t_1 = \min\bigl\{t \in\,]\omega_-, \omega_+ - T[\; \mid \varphi(t) = 0\bigr\},$$

$$t_2 = \max\bigl\{t \in\,]\omega_-, \omega_+ - T[\; \mid \varphi(t) = 0\bigr\}$$

and set

$$u_1 = x|_{[t_1, t_1+T]}, \quad u_2 = x|_{[t_2, t_2+T]}.$$

The T-periodic extensions to $\mathbb{R}$ of u_1, u_2 are solutions of (1.3).

If $u_1 = u_2$, we set $v = u_1 = u_2$. Observe that either $x(t_0) > v(t_0)$, or $x(t_0 + T) < v(t_0 + T)$. Suppose that $x(t_0) > v(t_0)$; the other case being treated similarly. Since $t_0 \in\,]t_1, t_2[$, we have that $\hat{x} = \max\{v, x|_{[t_1,t_2]}\}$ is a solution of (1.1) satisfying $\hat{x} > v$ on $[t_1, t_2]$, $\hat{x}(t_1) = v(t_1)$ and $\hat{x}(t_2) = v(t_2)$. Lemma 1.37 yields the existence of a nondegenerate continuum $\mathcal{K}$ satisfying the required conditions.

If $u_1 \neq u_2$ and $u_1(\bar{t}) = u_2(\bar{t})$ for some $\bar{t}$, then Lemma 1.34 implies the existence of a nondegenerate continuum $\mathcal{K}$ having the desired properties.

If $u_1 \ll u_2$, then $t_2 - t_1 > T$. The function $\hat{x} : \mathbb{R} \to \mathbb{R}$ defined by $\hat{x}(t) = u_1(t)$ on $]-\infty, t_1[$, $\hat{x}(t) = x(t)$ on $[t_1, t_2]$ and $\hat{x}(t) = u_2(t)$ on $]t_2, +\infty[$ is a solution of (1.1) satisfying $\hat{x}(t_1 + nT) = u_2(t_1 + nT) = u_2(t_1) > u_1(t_1) = \hat{x}(t_1)$, for all large $n \in \mathbb{N}$. Accordingly, $\hat{x}$ is not T-decreasing. On the other hand, $\hat{x}$ is not T-increasing. Otherwise $\varphi(t) \geqslant 0$ on $]\omega_-, \omega_+ - T[$ and hence x should be T-increasing as well, a contradiction. Therefore, $\hat{x}$ is not T-monotone and, by Step 1, we can find a nondegenerate continuum $\mathcal{K}$ satisfying the required conditions.

If $u_1 \gg u_2$, then there exist $a, b \in\,]\omega_-, \omega_+[$ such that $x(a) = u_2(a)$, $x(b) = u_2(b)$ and $x(t) > u_2(t)$ on $]a, b[$. Lemma 1.37 implies the existence of a nondegenerate continuum $\mathcal{K}$ having the desired properties. □

The Massera Convergence Theorem revisited

We are now in position of proving the announced extension of the Massera Convergence Theorem.

THEOREM 1.39. *Assume* (C). *Suppose that* $x :]t_0, +\infty[\to \mathbb{R}$ *is a bounded solution of* (1.1). *Then either*

- *there exists a solution u of* (1.3) *such that*

$$\lim_{t\to+\infty} \bigl|x(t) - u(t)\bigr| = 0, \tag{1.22}$$

or

- *the set* $\mathcal{C}$ *of all solutions* u *of* (1.3) *such that*

$$\liminf_{t\to+\infty}\left|x(t)-u(t)\right|=0 \tag{1.23}$$

is a nondegenerate closed connected subset of $C^0([0,T])$.

REMARK 1.19. It may happen that there exists a solution u of (1.3) such that x converges to u, nevertheless the set $\mathcal{C}$ is nondegenerate and even unbounded (see Example 1.2).

PROOF. Let us suppose that there is no solution u of (1.3) such that (1.22) holds. Then, by Proposition 1.7, x is not eventually T-monotone. We start by showing that $\mathcal{C}$ is not empty. Next we prove that $\mathcal{C}$ has at least two elements. Finally we show that $\mathcal{C}$ is closed and connected.

Step 1. *$\mathcal{C}$ is nonempty.* Let us denote by $\mathcal{S}_x$ the set of all solutions u of (1.3) for which there are unbounded sequences of real numbers $(a_n)_n$ and $(b_n)_n$ such that $u(a_n)<x(a_n)$ and $u(b_n)>x(b_n)$ for all n. Notice that $\mathcal{S}_x\subseteq\mathcal{C}$.

We claim that $\mathcal{S}_x$ is not empty. Assume by contradiction that $\mathcal{S}_x=\emptyset$. Since x is not eventually T-monotone, by Corollary 1.11 we can construct an increasing unbounded sequence $(a_n)_n$ of real numbers and a sequence $(u_n)_n$ of solutions of (1.3) such that either

$$u_n(a_n)<x(a_n)\quad\text{and}\quad u_n\geqslant x\quad\text{on } [a_{n+1},+\infty[,$$

or

$$u_n(a_n)>x(a_n)\quad\text{and}\quad u_n\leqslant x\quad\text{on } [a_{n+1},+\infty[,$$

for all n. We shall suppose that the former eventuality occurs. A similar argument can be used in the latter case. For each n, we set $\tilde{u}_n=\min\{u_1,u_2,\dots,u_n\}$. Notice that $\tilde{u}_n$ is a solution of (1.3), $\tilde{u}_n(a_n)<x(a_n)$ and $\tilde{u}_n\geqslant x$ on $[a_{n+1},+\infty[$. Since $\tilde{u}_n\geqslant\tilde{u}_{n+1}\geqslant\inf\{x(t)\mid t\in[t_0,+\infty[\}$ on $[0,T]$, the sequence $(\tilde{u}_n)_n$ converges uniformly to a solution u of (1.3), which satisfies $u(a_n)\leqslant\tilde{u}_n(a_n)<x(a_n)$ for all n.

Now, either $u\leqslant x$ on some interval $[b,+\infty[$ and hence $u\leqslant x\leqslant\tilde{u}_n$ on $[a_{n+1},+\infty[$ for all large n, or there is an increasing unbounded sequence of real numbers $(b_n)_n$ such that $u(b_n)>x(b_n)$. In the former case we conclude that (1.22) holds. In the latter case we conclude that $u\in\mathcal{S}_x$. In both cases we get a contradiction.

Step 2. *$\mathcal{C}$ is not a singleton.* Pick $u_0\in\mathcal{C}$. Since

$$0=\liminf_{t\to+\infty}\left|x(t)-u_0(t)\right|<\limsup_{t\to+\infty}\left|x(t)-u_0(t)\right|,$$

we can find a positive number ε and an increasing unbounded sequence of real numbers $(a_n)_n$ such that either $x(a_n)-u_0(a_n)>\varepsilon$ for all n or $u_0(a_n)-x(a_n)>\varepsilon$ for all n. We shall suppose that the former eventuality occurs. A similar argument can be used in the latter case.

Let us show that u_0 cannot be isolated from above in the set of all solutions u of (1.3). We proceed by contradiction. First assume that u_0 is the maximum solution of (1.3).

Let $y = \max\{u_0, x\}$. By Theorem 1.17 we should have either $\lim_{t\to+\infty} y(t) = +\infty$ or $\lim_{t\to+\infty}(y(t) - u_0(t)) = 0$; in both cases we get a contradiction. Next notice that, if there are a solution w of (1.3) and a point $\hat{t}$ such that $u_0 < w$ and $u_0(\hat{t}) = w(\hat{t})$, then, by Lemma 1.34, u_0 is not isolated from above. Finally suppose that there exists a solution w of (1.3) such that $u_0 \ll w$ and no solution u of (1.3) exists with $u_0 < u < w$. Set $y = \min\{\max\{x, u_0\}, w\}$. By Lemma 1.14 we should have either $\lim_{t\to+\infty}(y(t) - u_0(t)) = 0$ or $\lim_{t\to+\infty}(y(t) - w(t)) = 0$; in both cases we get again a contradiction.

Since u_0 is not isolated from above, we can pick a solution u of (1.3) with $u > u_0$ and $\|u - u_0\|_\infty < \varepsilon$. Then we have $u(a_n) < u_0(a_n) + \varepsilon < x(a_n)$ for all n. Since $\liminf_{t\to+\infty} |x(t) - u_0(t)| = 0$, we conclude that $u \in \mathcal{C}$ and therefore $\mathcal{C}$ has at least two elements.

Step 3. *$\mathcal{C}$ is closed and connected.* Since $\mathcal{C}$ is obviously closed, we only need to prove that it is connected. We start showing that $\mathcal{C}$ is dense-in-itself with respect to the order. Notice that if u is a solution of (1.3) and $u_1 < u < u_2$, then $u \in \mathcal{C}$. Assume first that $u_1(\hat{t}) = u_2(\hat{t})$ for some $\hat{t}$. Then, by Lemma 1.34, there exists a nondegenerate continuum of solutions u of (1.3) with $u_1 \leqslant u \leqslant u_2$. Assume next that $u_1 \ll u_2$ and that no solution u of (1.3) exists with $u_1 < u < u_2$. Set $y = \min\{\max\{x, u_1\}, u_2\}$. Then y is a nonextendible solution of (1.1) such that $u_1 < y < u_2$. By Lemma 1.14 we should have either $\lim_{t\to+\infty}(u_2(t) - y(t)) = 0$ or $\lim_{t\to+\infty}(y(t) - u_1(t)) = 0$, contradicting the fact that both u_1 and u_2 belong to $\mathcal{C}$.

Now, let $u_1, u_2 \in \mathcal{C}$ and assume $u_1 < u_2$. Let $\mathcal{T}$ be a nondegenerate maximal totally ordered subset of $\mathcal{C} \cap [u_1, u_2]$. By Lemma 1.3, $\mathcal{T}$ is an arc connecting u_1 and u_2. Accordingly, in order to prove that $\mathcal{C}$ is (arcwise) connected, it is enough to show that for every $u_1, u_2 \in \mathcal{C}$ there exists $u \in \mathcal{C}$ which is order-comparable with both u_1 and u_2. To achieve this aim, we set $v = \min\{u_1, u_2\}$ and $w = \max\{u_1, u_2\}$. We claim that either $v \in \mathcal{C}$ or $w \in \mathcal{C}$. Suppose $v \notin \mathcal{C}$. Then there exists $\varepsilon > 0$ and $\hat{t} \in \mathbb{R}$ such that $x(t) - v(t) > \varepsilon$ for all $t > \hat{t}$. Let us verify that $w \in \mathcal{C}$. Since $u_1 \in \mathcal{C}$, there exists an increasing unbounded sequence of real numbers $(a_n)_n$ with $|x(a_n) - u_1(a_n)| < \varepsilon$ for every n. If $\hat{n}$ is such that $a_{\hat{n}} > \hat{t}$, then $x(a_n) - v(a_n) > \varepsilon > |x(a_n) - u_1(a_n)|$ for all $n > \hat{n}$. Hence we deduce that $v(a_n) \neq u_1(a_n)$; therefore $u_1(a_n) = w(a_n)$ and $|x(a_n) - w(a_n)| < \varepsilon$ for all $n > \hat{n}$. ☐

The following statement conversely shows that each ω-limit point of a bounded solution defined on an unbounded interval must be in the range of a T-periodic solution.

PROPOSITION 1.40. *Assume* (C). *Suppose that* $x : [t_0, +\infty[\to \mathbb{R}$ *is a bounded solution of* (1.1). *Then, for each* $\hat{x}$, *with* $\liminf_{t\to+\infty} x(t) \leqslant \hat{x} \leqslant \limsup_{t\to+\infty} x(t)$, *and for each sequence* $(t_n)_n$, *with* $\lim_{n\to+\infty} t_n = +\infty$ *and* $\lim_{n\to+\infty} x(t_n) = \hat{x}$, *there exists a solution* u *of* (1.3) *such that* $\liminf_{n\to+\infty} |x(t_n) - u(t_n)| = 0$.

PROOF. If there exists a solution u of (1.3) such that (1.22) holds, the conclusion trivially follows. Hence we may assume that this is not the case. Let $\mathcal{C}$ be the set of all solutions u of (1.3) such that (1.23) holds. By Theorem 1.39, $\mathcal{C}$ is a nondegenerate closed connected set.

Step 1. Suppose that, for each n, $t_n = \hat{t} + k_n T$ with $\hat{t} \in [t_0, t_0 + T]$ and $k_n \in \mathbb{N}^+$. Let us show that there exists a function $u \in \mathcal{C}$ such that $u(\hat{t}) = \hat{x}$. We start by assuming, by contradiction, that $u(\hat{t}) < \hat{x}$ for all $u \in \mathcal{C}$.

Assume that $\mathcal{C}$ is bounded from above. Then, by Lemma 1.15, there exists a maximal element w of $\mathcal{C}$. We first observe that there is no $\bar{t} > t_0$ such that $x > w$ on $[\bar{t}, +\infty[$. Suppose not. Since $0 = \liminf_{t\to+\infty} |x(t) - w(t)| < \limsup_{t\to+\infty} |x(t) - w(t)|$, by Theorem 1.17 there exists a solution u of (1.3) such that $w < u$, and, by Lemma 1.14, w is not isolated from above in the set of all solutions u of (1.3). Hence there exists a sequence $(w_k)_k$ of solutions of (1.3), converging uniformly to w and such that $w_k > w$ for all k. Since $\limsup_{t\to+\infty} |x(t) - w(t)| > 0$, there exists k such that $w_k \in \mathcal{C}$, thus yielding a contradiction to the maximality of w. Nevertheless, since $w(\hat{t}) < \hat{x} = \lim_{n\to+\infty} x(t_n)$, there are $\varepsilon > 0$ and $\bar{n}$ such that $w(\hat{t}) = w(t_n) < \hat{x} - \varepsilon < x(t_n)$ for all $n \geqslant \bar{n}$. Hence there exist a sequence of positive integers $(n_j)_j$, with $n_0 \geqslant \bar{n}$, and sequences of real numbers $(a_j)_j$ and $(b_j)_j$, with $a_j < t_{n_j} < b_j$ such that $w(a_j) = x(a_j)$, $w(b_j) = x(b_j)$ and $x(t) > w(t)$ on $]a_j, b_j[$ for all j. By Lemma 1.37, there exists a solution u_0 of (1.3) such that $u_0 \geqslant w$ and $u_0(t_{n_0}) = \hat{x} - \varepsilon$. Notice that, for all j, we both have $u_0(t_{n_j}) = \hat{x} - \varepsilon < x(t_{n_j})$ and $x(a_j) = w(a_j) \leqslant u_0(a_j)$. Hence $u_0 \in \mathcal{C}$, a contradiction with the maximality of w.

Assume now that $\mathcal{C}$ is unbounded from above. Then there exists $w \in \mathcal{C}$ such that $\max w > \sup x$. Let $a \in]\hat{t} - T, \hat{t}[$ be such that $w(a) = \max w$. Since $w(\hat{t}) < \hat{x} = \lim_{n\to+\infty} x(t_n)$, there are an integer $\bar{n}$ and an increasing sequence $(p_n)_n$ of real numbers such that $\lim_{n\to+\infty} p_n = \hat{x}$ and, for all $n \geqslant \bar{n}$, $w(\hat{t}) = w(t_n) < p_n < \min\{x(t_n), \hat{x}\}$. For each $n \geqslant \bar{n}$, let $w_n \colon [a + k_n T, a + (k_n + 1)T] \to \mathbb{R}$ be the function defined by $w_n(t) = \max\{w(t), x(t)\}$. Notice that $w_n(a + k_n T) = w(a + k_n T) = w(a)$, $w_n(a + (k_n + 1)T) = w(a + (k_n + 1)T) = w(a)$ and $w_n > w$ on $[a + k_n T, a + (k_n + 1)T]$. Since $w(t_n) < p_n < w_n(t_n)$, by Lemma 1.37, there exists a solution v_n of (1.3) such that $v_n \geqslant w$ and $v_n(t_n) = p_n$. Let $u_n = \min\{v_n, w_n\}$. Then, for each $n \geqslant \bar{n}$, $u_n(a) = w(a)$ and $u_n(\hat{t}) = p_n$. Hence, for all $n \geqslant \bar{n}$, both $u_{\bar{n}}(a + k_n T) = \max w > x(a + k_n T)$ and $u_{\bar{n}}(t_n) = p_{\bar{n}} \leqslant p_n < x(t_n)$, and therefore $u_{\bar{n}} \in \mathcal{C}$. Furthermore, the sequence $(u_n)_n$ is bounded and hence there is a subsequence $(u_{n_j})_j$ converging uniformly to a function $u \in \mathcal{C}$. Since $u_{n_j}(\hat{t}) = p_{n_j}$, we get $u(\hat{t}) = \hat{x}$, a contradiction.

In a similar way we can show that the assumption that $u(\hat{t}) > \hat{x}$ for all $u \in \mathcal{C}$ leads to a contradiction. Hence either there exists $u \in \mathcal{C}$ such that $u(\hat{t}) = \hat{x}$, or there exist $u_1, u_2 \in \mathcal{C}$ with $u_1(\hat{t}) \leqslant \hat{x} \leqslant u_2(\hat{t})$. In the latter case the connectedness of $\mathcal{C}$ yields anyhow the existence of a function $u \in \mathcal{C}$ such that $u(\hat{t}) = \hat{x}$.

Step 2. Let us show that we can always reduce ourselves to the situation considered in Step 1. Namely, for each n let k_n be the integer such that $t_n \in [t_0 + k_n T, t_0 + (k_n + 1)T[$ and set $\hat{t}_n = t_n - k_n T$. Let $\hat{t} \in [t_0, t_0 + T]$ be a cluster point of the sequence $(\hat{t}_n)_n$ and pick a subsequence $(\hat{t}_{n_j})_j$ converging to $\hat{t}$. Set $s_j = \hat{t} + k_{n_j} T$. Notice that $\lim_{j\to+\infty} |t_{n_j} - s_j| = \lim_{j\to+\infty} |\hat{t}_{n_j} - \hat{t}| = 0$. Since the function x is uniformly continuous on $[t_0, +\infty[$, we have $\lim_{j\to+\infty} |x(t_{n_j}) - x(s_j)| = 0$ and therefore $\lim_{j\to+\infty} x(s_j) = \hat{x}$. By Step 1 there exists a solution u of (1.3) such that $\liminf_{j\to+\infty} |x(s_j) - u(s_j)| = 0$. Since $|x(t_{n_j}) - u(t_{n_j})| \leqslant |x(t_{n_j}) - x(s_j)| + |x(s_j) - u(s_j)| + |u(s_j) - u(t_{n_j})|$, $\lim_{j\to+\infty} |x(t_{n_j}) - x(s_j)| = 0$ and $\lim_{j\to+\infty} |u(s_j) - u(t_{n_j})| = \lim_{j\to+\infty} |u(\hat{t}) - u(\hat{t}_{n_j})| = 0$, we conclude that $\liminf_{n\to+\infty} |x(t_n) - u(t_n)| = 0$. □

REMARK 1.20. In the light of Proposition 1.38, Proposition 1.7 and Theorem 1.39, one might guess that, if $x :]t_0, +\infty[\to \mathbb{R}$ is a bounded solution of (1.1), which is not eventually T-monotone, then the set $\mathcal{C}$ of all solutions u of (1.3), such that $\liminf_{t\to+\infty} |u(t) - x(t)| =$

0, is always a nondegenerate connected set. Yet, as the next example shows, this is not actually true.

EXAMPLE 1.5. We construct a function f, which is 1-periodic with respect to the t-variable, such that equation (1.1) has a bounded solution x that is not eventually 1-monotone, but the set $\mathcal{C}$ of all solutions u of (1.3), such that $\liminf_{t\to+\infty} |u(t) - x(t)| = 0$, is a singleton $\mathcal{C} = \{u\}$ and actually $\lim_{t\to+\infty}(u(t) - x(t)) = 0$. Our construction is based on a modification of Example 1.4. Let $h : \mathbb{R} \to \mathbb{R}$ be the 1-periodic function defined by $h(t) = -\frac{1}{8}|t|$ on $[-\frac{1}{2}, \frac{1}{2}[$. Let us define f by setting, for every t, $f(t, x) = \sqrt{|x|} + h(t)$, if $x \leqslant -\frac{1}{8}$, $f(t, x) = \sqrt{|x - 2 + \frac{1}{2^{n-1}}|} + \frac{1}{2^n}h(t)$, if $n \geqslant 0$ and $x \in [2 - \frac{17}{2^{3+n}}, 2 - \frac{15}{2^{3+n}}]$, $f(t, x) = 0$, if $x \geqslant 2$. Then we extend f onto $\mathbb{R}^2$ by linear interpolation with respect to x. We can see that Eq. (1.1) has a sequence $(\mathcal{K}_n)_n$ of continua of 1-periodic solutions, which approximate the equilibrium $w \equiv 2$. Each continuum $\mathcal{K}_n$ is a "squeezing" of the continuum $\mathcal{K}$ produced in Example 1.4. Denote by v_n and w_n respectively the minimum and the maximum of $\mathcal{K}_n$. One can verify that for each n, between w_n and v_{n+1}, all solutions are heteroclinics that leave w_n and reach v_{n+1} in a finite time. Indeed, for any $m_n \in \mathbb{Z}$ we can find a solution y_n of (1.1) which pulls ahead of w_n at m_n and reaches the value $2 - \frac{15}{2^{3+n}}$ in a finite time. Since f is positive there, y_n enters a region where f is defined linearly. There y_n is still increasing until it reaches the value $2 - \frac{17}{2^{4+n}}$, where f is still positive. Then y_n enters a region where all solutions reach v_{n+1} in a finite time.

Let us now outline a possible construction of the solution x of (1.1) having the required properties. Start taking x on [0, 1] to be any $x_1 \in \mathcal{K}_1$. Then there is a solution y_1 of (1.1), which pulls ahead of w_1 at $m_1 = 1$ and reaches v_2 in a finite time. On this interval x is y_1. Afterwards, we take x to be for a while an almost periodic solution lying between v_2 and w_2, careful enough to destroy 1-monotonicity. Then we pull ahead of w_2 at some m_2 and we define x to be a function of the form of y_2. Proceeding in this way we get our desired solution x.

A careful reading of our construction actually shows that x can be defined so that it is not T-monotone for any fixed $T > 0$.

2. Second Order Periodic Parabolic PDEs

2.1. *Introduction*

In this part we consider the parabolic boundary value problem

$$\begin{cases} \partial_t u + A(x, t, \partial_x)u = f(x, t, u, \nabla_x u) & \text{in } \Omega \times I, \\ u = 0 & \text{on } \partial\Omega \times I. \end{cases} \tag{2.1}$$

Here Ω is a bounded smooth domain in $\mathbb{R}^N$, with $N \geqslant 1$, I is a real interval, $\partial_t + A(x, t, \partial_x)$ is a linear second order uniformly parabolic operator. The coefficients of A are T-periodic in t, $T > 0$ being a given period. The function $f : \Omega \times \mathbb{R} \times \mathbb{R} \times \mathbb{R}^N \to \mathbb{R}$ is T-periodic in t and satisfies the L^p-Carathéodory conditions, for some $p > N + 2$, as well as a Nagumo condition, that is, $f(x, t, s, \xi)$ grows at most quadratically with respect to ξ. According to these assumptions, it is natural to consider solutions of (2.1) intended in the strong, i.e. $W_p^{2,1}$-, sense. In this work for simplicity we only deal with homogeneous Dirichlet data in (2.1), however more general boundary conditions, such as Robin and mixed ones, could be considered as well (see [42]).

Nonlinear diffusion equations such as (2.1) typically occur in the mathematical description of various biological, chemical, physical and economical phenomena and they have particular interest in population ecology models where the data periodically depend on time due to seasonal fluctuations (see, e.g., [49,58,155,25,115,103]).

We are mainly interested here in studying existence, localization and qualitative properties of the T-periodic solutions of (2.1), assuming that a lower solution α and an upper solution β of the T-periodic problem associated with (2.1) are given.

If we suppose that the L^p-Carathéodory function f satisfies further regularity assumptions, e.g., f is locally Lipschitz continuous with respect to s and ξ, then the initial value problem associated with (2.1) is well-posed, i.e. it has a unique solution which depends continuously on the given data; moreover, the regularity of f, in conjunction with the parabolic maximum principle, yields the validity of comparison principles of Nagumo-Westphal type (see [151,106]). In this frame the Poincaré operator associated with (2.1), which assigns to every initial datum the value of the solution after one period, is well-defined and strictly order preserving; so that the above mentioned questions can be tackled by the theory of order preserving discrete-time semidynamical systems as in [58,60]. Our perspective in this work is different. Here we assume that f satisfies only the L^p-Carathéodory conditions: in this case evidently such theory does not apply, due to the failure both of uniqueness for the initial value problem and of comparison principles. Nevertheless, we shall see that a careful direct analysis of the partial differential equation (2.1) allows to reinterpret, or to adapt to a more general setting, or to extend the validity of several results which are known within the frame of order preserving dynamical systems, always keeping minimal regularity assumptions.

The study of the existence of periodic solutions of certain special forms of (2.1) seems to have been initiated in the late thirties and continued in the forties by D.H. Karimov [64–67]. In the early fifties, G. Prodi [125–127] introduced lower and upper solutions and a Nagumo-type condition for studying the solvability of the periodic problem associated with (2.1). The stability of periodic solutions was also discussed by G. Prodi in [124], using the concept of Lyapunov stability as extended to parabolic equations by R. Bellmann [17]. In the fifties and the sixties, further progress was obtained, concerning both existence and stability (see, e.g., [107,137,75,23,69,48,12,138,70,78]). These authors approached the problem by various methods and techniques, but still only special cases of (2.1) were considered. A general answer to the question of the existence of a T-periodic solution, when the lower and the upper solutions satisfy

$$\alpha(x,t) \leqslant \beta(x,t) \quad \text{in } \Omega \times \left]0,T\right[, \tag{2.2}$$

was eventually given by Ju.S. Kolesov [72,73] in the late sixties. Namely, under additional regularity assumptions on the coefficients and the nonlinearity, he proved the existence of a classical T-periodic solution u of (2.1) such that

$$\alpha(x,t) \leqslant u(x,t) \leqslant \beta(x,t) \quad \text{in } \Omega \times \left]0,T\right[. \tag{2.3}$$

This result was improved by H. Amann [6,8] in the seventies. In particular, he proved some basic estimates in connection with the above mentioned Nagumo condition, established the existence of a minimum and of a maximum T-periodic solution between α and β and also allowed Robin boundary conditions in (2.1).

The method of Ju.S. Kolesov and H. Amann consists in finding periodic solutions of (2.1) as fixed points of the Poincaré operator associated with (2.1), whose existence is guaranteed by the smoothness assumptions on f. Further, it was observed apparently for the first time in [8] that the Poincaré operator has the important property of being strongly order preserving with respect to the order induced by the positive cone of $C_0^1(\overline{\Omega})$. In [8] and other related works, this property follows from the validity of a strong comparison principle of the Nagumo–Westphal type for (2.1), which is in turn a consequence of the linear parabolic maximum principle and, again, of the smoothness of f.

These ideas are useful for solving both theoretically and numerically the periodic problem associated with (2.1), but they also revealed to be quite fruitful for investigating the stability properties of the periodic solutions of (2.1). Indeed, strongly influenced by some works of H. Matano [92,93] who successfully integrated monotonicity methods with dynamical systems techniques for the study of autonomous parabolic initial value problems (see also M.W. Hirsch [59] and H.L. Smith [136]), E.N. Dancer and P. Hess [33] were able to provide, remaining in the same frame of [8], an answer to the question of the stability of periodic solutions of (2.1). Namely, they proved that, if α and β are strict lower and upper solutions, for which (2.2) holds, then there exists at least one T-periodic solution u satisfying (2.3) which is stable. Although preliminary results in this direction can be found, e.g., in [71,72,134,92], the novelty of the approach of E.N. Dancer and P. Hess lies in the introduction of a strongly order preserving discrete-time semidynamical system, which allows to detect many qualitative properties of the initial value problems associated with (2.1). In [33] this discrete-time semidynamical system is determined by the solution operator corresponding to the T-periodic problem related to (2.1), although the smoothness assumptions imposed on (2.1) would allow to consider as well the discrete-time semidynamical system induced by the Poincaré operator. In their successive paper [34], as well as in the monograph by P. Hess [58], the approach based on the Poincaré operator was developed in an abstract setting and systematically employed to describe the dynamics of (2.1). Thus, several stability, instability and stabilization results for the T-periodic solutions of (2.1) were obtained. In particular, the existence of heteroclinic orbits, connecting periodic solutions, was established, extending previous results, such as those in [93]. In [32] E.N. Dancer carried on these studies further, investigating the relations between fixed point index, one-sided stability and existence of lower and upper solutions close to a periodic solution, as well as the possibility of weakening the order preserving requirements on the semiflow. Further progress in the theory of discrete-time order preserving semidynamical systems has been obtained in the last ten years; we refer to the very recent works [60,123,61] for updated surveys on this theory, as well as on its applications to parabolic boundary value problems of the form of (2.1).

We notice that all the above cited papers deal with classical solutions of (2.1); whereas, the existence and localization of weak T-periodic solutions in the presence of lower and upper solutions were discussed in [44], even for more general quasilinear equations. In this frame, the existence of a minimum and a maximum solution was established in [26] and their one-sided stability in [46]. To the best of our knowledge, strong solutions have not been explicitly considered in the literature in connection with lower and upper solutions, although they naturally occur in the Carathéodory frame.

So far we have considered situations dealing with pairs of lower and upper solutions satisfying (2.2). Now, we turn to discuss the complementary case where there exist a lower solution α and an upper solution β for which condition (2.2) fails, that is,

$$\alpha(x_0, t_0) > \beta(x_0, t_0) \quad \text{for some } (x_0, t_0) \in \Omega \times \,]0, T[. \tag{2.4}$$

There are concrete motivations to consider this situation. Indeed, condition (2.2) turns out to be restrictive in some situations. This was remarked by J. Kazdan and F. Warner [68] for elliptic equations, but their observation immediately extends to periodic parabolic problems. Let us denote by λ_1 the principal eigenvalue of the linear T-periodic problem associated with (2.1). Assume for example that the function f in (2.1) is independent of $\nabla_x u$. If f satisfies

$$\operatorname*{ess\,sup}_{\Omega\times]0,T[\times\mathbb{R}} \partial_s f(x, t, s) < \lambda_1, \tag{2.5}$$

then one can construct lower and upper solutions α, β satisfying (2.2). On the other hand, if f satisfies

$$\operatorname*{ess\,inf}_{\Omega\times]0,T[\times\mathbb{R}} \partial_s f(x, t, s) > \lambda_1 \tag{2.6}$$

then, for any pair of lower and upper solutions α, β satisfying (2.2), one easily verifies that $\alpha = \beta$ and they must already be solutions. Hence any result involving such lower and upper solutions is of no use here. Yet, in this situation lower and upper solutions satisfying (2.4) occur quite naturally. Indeed, one can show that condition (2.6) implies the existence of pairs of lower and upper solutions α, β such that

$$\alpha(x, t) > \beta(x, t) \quad \text{in } \Omega \times \,]0, T[. \tag{2.7}$$

Moreover, the principle of linearized instability suggests that, if a T-periodic solution of (2.1) existed in the presence of lower and upper solutions satisfying (2.4), it should be presumably unstable, unlike what has been established when (2.2) holds. This was conjectured in the frame of elliptic boundary value problems by D.H. Sattinger [134], who was the first to pose these questions in the early seventies. Afterwards, it was pointed out in [7] that the mere existence of a lower solution and an upper solution for which (2.4) holds is generally not sufficient to guarantee the solvability. Adapted to our setting, the example in [7] is of the following type:

$$\begin{cases} \partial_t u - \Delta u = \lambda_m u + \varphi_m & \text{in } \Omega \times \,]0, T[, \\ u = 0 & \text{on } \partial\Omega \times [0, T], \\ u(\cdot, 0) = u(\cdot, T) & \text{in } \Omega, \end{cases} \tag{2.8}$$

where λ_m is an eigenvalue of $-\Delta$ on $H_0^1(\Omega)$ greater than λ_1 and φ_m is a corresponding nonzero eigenfunction. Of course, problem (2.8) has no solution, although one can construct a lower solution α and an upper solution β satisfying (2.4). Accordingly, one is led to conclude that, to achieve solvability, some further conditions must be assumed, in order to prevent the interference of f with the higher part of the spectrum. This can be expressed in various ways. In [9], where the first important contribution was given in the frame of elliptic equations, H. Amann, A. Ambrosetti and G. Mancini proved that the existence of a lower solution α and of an upper solution β, not necessarily satisfying any ordering condition, implies solvability, provided f is a bounded perturbation of $\lambda_1 s$. Further results, mainly in the direction of weakening this last condition, as well as of obtaining information on the localization of the solution, were later proved, always for elliptic equations, in [54,55,40]. In [41] the existence result of [40] was extended to the periodic problem for (2.1) and, apparently for the first time, the study of the stability properties was faced in this context. Indeed, assuming the existence of strict lower and upper solutions satisfying (2.4) and some growth restrictions on f, it was proved in [41] the existence of a solution u of (2.1), which is unstable and satisfies, for some $(x_1, t_1), (x_2, t_2) \in \Omega \times]0, T[$,

$$u(x_1, t_1) < \alpha(x_1, t_1) \quad \text{and} \quad u(x_2, t_2) > \beta(x_2, t_2). \tag{2.9}$$

We stress that this result is the direct counterpart of the one in [33] when condition (2.2) is replaced by (2.4), because it yields the existence of a solution, information about its localization in terms of α and β and its instability. We further notice that in [41] the analysis was entirely performed in the frame of strong solutions of (2.1) without requiring, unlike [33] and the other quoted results, any further regularity on f in addition to the Carathéodory conditions.

It should be observed that in several cases the principles of linearized stability, or the construction of Lyapunov functionals, can be successfully used to detect the stability of periodic solutions (see, e.g., [37,154,123]). On the other hand, the use of lower and upper solutions for discussing the stability properties of a periodic solution appears appropriate in some critical cases where such methods fail, in particular when the periodic solution under consideration is degenerate, or the nonlinearity f does not satisfy the necessary differentiability requirements, and obviously in all situations where the existence of a Lyapunov functional is not known. This remark also provides a strong motivation for studying the applicability of the lower and upper solution method to detect stability, or instability, and to investigate other qualitative properties, assuming the least of regularity on f. In this work we pursue this program.

The remainder of this introduction is devoted to describe with some detail the plan of this part of our work.

In Section 2.2 we collect some definitions and preliminary statements, having a basic or technical nature, which will be extensively used in the sequel. Most of these are variations or extensions of known ones. Nevertheless, we state them in a precise form, providing even proofs, whenever we are not able to supply adequate references. We introduce in particular a rather general notion of lower and upper solutions for problem (2.1), which appear appropriate in the frame of strong solutions. Namely, a lower solution is defined, locally in time, as the pointwise maximum of a finite number of $W_p^{2,1}$-lower solutions. Similarly an upper solution is defined, locally in time, as the pointwise minimum of a finite number of $W_p^{2,1}$-upper solutions. In this way we allow "angles" in the space variables and "jumps" in the time variable. This level of generality is motivated by the fact that "angles" and "jumps" naturally occur in practical and theoretical situations even in the frame of smooth solutions: typically when considering minima or maxima of solutions, which are not solutions due to the lack of lattice structure, or studying solutions of the initial value problem lying between lower and upper solutions of the periodic problem. After reviewing a parabolic maximum principle for strong solutions, some notions of orderings, order norms and other topics, we further prove in Proposition 2.3 an elementary fact, which, roughly speaking, says that any Carathéodory function satisfies a local regularity condition, which is the natural generalization of the Lipschitz or Hölder continuity and will allow us to compare problem (2.1) with other ones possessing a certain extent of monotonicity. This simple observation has also some interesting connections with the use of a monotone iterative scheme, namely the Chaplyghin method (see [100,13,8]), for the construction of the minimum and the maximum solution of (2.1), lying between a lower and an upper solution satisfying (2.2). However, for brevity, we do not discuss this topic here and we refer to [42].

In Section 2.3 we describe some basic facts concerning the initial value problem associated with (2.1). Namely, we discuss existence, localization and structure of the set of strong solutions of (2.1) in the presence of a pair of possibly discontinuous lower and upper solutions satisfying (2.2). A crucial step of this section is the Nagumo-type result stated in Proposition 2.5 (a different version suited for the periodic problem will be proved later in Proposition 2.10): these statements basically show that suitable $W_p^{2-2/p}$-, or L^∞-, bounds on the initial values force $W_p^{2,1}$-bounds on the solutions of (2.1), provided f satisfies a Nagumo condition. We reproduce in both cases their rather delicate proofs in detail, even if these follow the argument in [6], because some specifications are needed in order to extend their validity to our setting. Then we prove the main results of this section: Theorem 2.6, dealing with compact cylinders, and Corollary 2.7, dealing with noncompact cylinders. They extend to strong solutions and possibly discontinuous lower and upper solutions some existence and localization results for the initial value problem associated with (2.1) which are well known in the frame of classical solutions. We also describe the topological structure of the solution set, proving the Hukuhara–Kneser property. Since our analysis is performed just assuming that f satisfies the Carathéodory conditions, we get an improvement of previous statements obtained in [76], for f Hölder continuous, and in [81], for f continuous. Our proof uses an abstract theorem in [77,153], but differs from the standard ones in the approximation method, as we adapt here an idea introduced in [139] dealing with ordinary differential equations. As a byproduct we get, by a simple proof, a basically known result concerning local existence, continuation and ultimate behaviour of solutions of (2.1).

Section 2.4 is devoted to some existence and localization statements for the periodic problem associated with (2.1), when a pair α, β of possibly discontinuous lower and upper solutions is given. After some preliminaries, mainly devoted to state the above mentioned Nagumo-type result for the periodic problem, we introduce in the frame of (2.1) the notion of T-monotonicity. This property is a simple tool to prove convergence of a bounded solution defined in $\overline{\Omega} \times [t_0, +\infty[$ to a T-periodic solution. We use it to get an extension to the present context of the Monotone Convergence Criterion known in the frame of order preserving discrete-time semidynamical systems (see, e.g., [60, Section 5]). The version of this criterion we give in Proposition 2.13 says that any bounded solution of (2.1) emanating from and lying above a lower solution of the T-periodic problem associated with (2.1), or respectively emanating from and lying below an upper solution, is T-monotone and hence converges to a T-periodic solution. We point out that, in space dimension $N \geqslant 2$, convergence to a T-periodic solution is not the behaviour of all bounded solutions of (2.1), due to the possible occurrence of subharmonic solutions (see, e.g., [141,35] and [123, Section 3]). In our frame additional difficulties come from the lack of regularity of f, so that even generic convergence results fail (see [123, Section 3]). We then give an application of this result to the existence of strong periodic solutions of the linear problem associated with (2.1). Although this topic was recently considered in [84], we show here that a simple approach, based on a monotone iterative scheme, yields a constructive existence proof. This technique is very much in the spirit of this work, since the iteration here introduced is used several times elsewhere in the paper. Additional statements concerning the principal eigenvalue λ_1 of the linear problem associated with (2.1), as well as some Fredholm-type results, are produced in Appendix.

After these premises, which however have an independent interest, we prove the main theorems of this section: the existence and localization of solutions of the periodic problem associated with (2.1) when $\alpha \leqslant \beta$, or when $\alpha \nleqslant \beta$. Theorem 2.15 yields the existence of a minimum and a maximum T-periodic solution of (2.1) between two possibly discontinuous lower and upper solutions α, β satisfying the condition $\alpha \leqslant \beta$. This extends to strong solutions previous results obtained, e.g., in [73,8,6,33,58] for classical solutions. The proof of Theorem 2.15 makes use of a quite standard argument, substantially similar to that used for proving Theorem 2.6. Nevertheless, as its counterpart for the initial value problem, the modification and truncation method we use are new in this frame, since some specific devices are required in order to deal with nonregular lower and upper solutions, as well as with Carathéodory gradient dependent nonlinearities, for handling which some care is required. We also show the existence of a minimum and of a maximum solution using a neat argument based on compactness. For later use, relations with the topological degree are also established, when the lower and upper solutions are strict.

Afterwards we discuss the existence of T-periodic solutions of (2.1) in the presence of generalized lower and upper solutions α, β such that $\alpha \nleqslant \beta$. As we already pointed out, in this frame the sole existence of a pair of lower and upper solutions, even satisfying $\alpha > \beta$, does not generally guarantee the existence of a solution. Here we prove in Theorem 2.17 a result which is related to the classical Amann–Kolesov Three Solutions Theorem [73,5,7] and requires the existence of a further pair of lower and upper solutions α_1, β_1, with $\alpha_1 \leqslant \beta_1$, bracketing α, β. Theorem 2.17 then yields the existence of maximal and minimal T-periodic solutions of (2.1) lying between α_1, β_1 and belonging to the $C^{1,0}$-closure of the set of functions satisfying (2.9). The solvability is established evaluating, by means of the additivity and excision properties, the topological degree of a solution operator associated with (2.1), whose fixed points are precisely the periodic solutions of (2.1). The existence of minimal and maximal solutions is proved using some a-priori bounds in connection with Zorn Lemma. For related results we refer to [41,42], where alternative conditions are used and several applications are indicated.

The aim of Section 2.5 is to extend to our general context the Order Interval Trichotomy, first proved in [34] for order preserving discrete-time semidynamical systems. We stress once more that our results are obtained without requiring any regularity on the function f besides the Carathéodory conditions. Nevertheless with the aid of Proposition 2.3, which plays a crucial role in this context, we can make deformations of our original problem to other problems displaying a certain amount of monotonicity, from which we eventually infer the information needed to prove the existence of some type of connections. Namely, if we fix an ordered pair of T-periodic solutions, say u_1, u_2, then we prove the existence either of a further T-periodic solution between u_1 and u_2, or of a double sequence of lower, or upper, solutions connecting u_1 and u_2. The last assertion expresses a form of stability, or instability, of u_1 and u_2, which is referred to as order stability. Once this version of the Order Interval Trichotomy is established, we apply it to the study of the dynamics near one-sided isolated T-periodic solutions of (2.1). Namely we prove the existence of T-monotone heteroclinic solutions connecting a pair of comparable T-periodic solutions and we study the qualitative behaviour of certain solutions of (2.1) lying above a maximal, or below a minimal, T-periodic solution. Our statements extend previous results in [34,58, 32] (see also [60,123]).

In Section 2.6 we study the stability properties of the T-periodic solutions of (2.1) with the aid of lower and upper solutions. We start by recalling the definition of one-sided Lyapunov–Bellmann stability. Instead of using the more usual C^1-, or L^∞-, norm for measuring the distance between solutions, we use the order norm induced by a fixed function belonging to the interior of the positive cone in $C_0^1(\overline{\Omega})$. This seems natural in order to fit better with the features of (2.1) and with our approach. Since we have to take care of the fact that uniqueness for the initial value problem and validity of comparison principles are not assumed, the notion of Lyapunov stability may be not the most appropriate to be considered here; indeed, some weaker concept might be more suited to detect certain residual forms of stability. As an alternative definition to Lyapunov stability we consider that of order stability; this is commonly used in the frame of order preserving semidynamical systems [93,33,58,60] and appears suited to our approach based on lower and upper solutions. We perform a rather detailed examination of the relationship occurring between the notions of Lyapunov and order stability. In particular we discuss the meaning of these notions of stability, when some versions of the comparison principle hold for solutions of (2.1), implying or not uniqueness for the initial value problem. Explicit conditions on the nonlinearity f, entailing their validity, are also exhibited. We show in particular that Lyapunov stability implies order stability, whereas the converse implication is not generally true; however, these concepts are equivalent if a comparison principle holds. Using these notions, we give a precise description of the stability properties of a T-periodic solution in terms of the existence of a lower or an upper solution close to it. Hence, when a pair of lower and upper solutions α, β, with $\alpha \leqslant \beta$, is given, we discuss the stability of the minimum and the maximum T-periodic solutions v and w lying in between, thus getting a completion of Theorem 2.15. Namely, as a consequence of Proposition 2.13 we prove, in Theorem 2.33, an invariance property of the set of T-periodic solutions which lie between a lower and an upper solution satisfying (2.2) and, in particular, a form of relative attractivity of the minimum and the maximum solutions. Afterwards, we discuss the structure of the set of T-periodic solutions lying between v and w, as well as the dynamics occurring between them. In particular, we prove the existence of a totally ordered continuum of order stable solutions. Assuming the validity of some comparison principle, we obtain refinements and strengthenings of the results we have established in a more general context. In particular we can recover several known results, about stability, asymptotic stability, instability of periodic solutions, using an approach which singles out the essential hypotheses. Finally, we describe with some detail the instability properties of maximal T-periodic solutions which are not above a strict lower solution, or not below a strict upper solution. As a consequence, in the case where $\alpha \not\leqslant \beta$, we get an instability result which completes the conclusions of Theorem 2.17. The last subsection is devoted to a discussion of some relations between stability properties and multiplicity of T-periodic solutions.

2.2. *Preliminaries*

In this section we state some basic facts concerning the parabolic problem

$$\begin{cases} \partial_t u + A(x,t,\partial_x)u = f(x,t,u,\nabla_x u) & \text{in } \Omega \times I, \\ u = 0 & \text{on } \partial\Omega \times I, \end{cases} \tag{2.10}$$

where $I \subseteq \mathbb{R}$ is an interval.

Basic assumptions

We suppose that

(D) $\Omega \subset \mathbb{R}^N$ is a bounded domain, having a boundary $\partial\Omega$ of class C^2, and $T > 0$ is a fixed number.

Hereafter, we set $Q_T = \Omega \times]0,T[$ and $\Sigma_T = \partial\Omega \times [0,T]$. The differential operator has the form

$$A(x,t,\partial_x)u = -\sum_{i,j=1}^{N} \partial_{x_i}\big(a_{ij}(x,t)\partial_{x_j}u\big) + \sum_{i=1}^{N} a_i(x,t)\partial_{x_i}u + a_0(x,t)u.$$

We assume that

(A) $a_{ij} \in C^{1,0}(\overline{Q}_T)$, $a_{ij}(x,t) = a_{ji}(x,t)$ in $\overline{Q}_T$, $a_{ij}(x,0) = a_{ij}(x,T)$ in $\overline{\Omega}$, for $i,j = 1,\dots,N$, and there exists $\eta > 0$ such that, for all $(x,t) \in \overline{Q}_T$ and $\xi \in \mathbb{R}^N$,

$$\sum_{i,j=1}^{N} a_{ij}(x,t)\xi_i\xi_j \geqslant \eta|\xi|^2;$$

$a_i \in L^\infty(Q_T)$ for $i = 0,\dots,N$; $\operatorname{ess\,inf}_{Q_T} a_0 > 0$.

We further suppose that

(C) $f : Q_T \times \mathbb{R} \times \mathbb{R}^N \to \mathbb{R}$ satisfies the L^p-Carathéodory conditions for some $p > N+2$, i.e. for every $(s,\xi) \in \mathbb{R} \times \mathbb{R}^N$, $f(\cdot,\cdot,s,\xi)$ is measurable on Q_T; for a.e. $(x,t) \in Q_T$, $f(x,t,\cdot,\cdot)$ is continuous on $\mathbb{R} \times \mathbb{R}^N$; for each $\rho > 0$, there exists $\gamma \in L^p(Q_T)$ such that $|f(x,t,s,\xi)| \leqslant \gamma(x,t)$, for a.e. $(x,t) \in Q_T$ and every $(s,\xi) \in [-\rho,\rho] \times [-\rho,\rho]^N$;

and

(N) for every $M > 0$, there exist $h \in L^p(Q_T)$, with $p > N+2$, and $K > 0$ such that for a.e. $(x,t) \in Q_T$, every $s \in [-M, M]$ and every $\xi \in \mathbb{R}^N$,

$$\left|f(x,t,s,\xi)\right| \leqslant h(x,t) + K|\xi|^2. \tag{2.11}$$

REMARK 2.1. All functions considered in (A) and (C) are identified with their T-periodic extensions onto $\Omega \times \mathbb{R}$ and $\Omega \times \mathbb{R} \times \mathbb{R} \times \mathbb{R}^N$, respectively.

Solutions and lower and upper solutions

We notice that, assuming (D) and $p > N+2$, the Sobolev space $W_p^{2,1}(\Omega \times]t_1, t_2[)$, with $t_1, t_2 \in \mathbb{R}$ and $t_1 < t_2$, is (compactly) embedded into $C^{1,0}(\overline{\Omega} \times [t_1, t_2])$ (see [80, Chapter II, Section 3]). Accordingly, the following definitions make sense.

DEFINITION 2.1.

- A *solution of* (2.10) *in* $\overline{\Omega} \times [t_1, t_2]$, with $t_1, t_2 \in \mathbb{R}$ and $t_1 < t_2$, is a function $u \in W_p^{2,1}(\Omega \times]t_1, t_2[)$ such that

$$\begin{aligned} &\partial_t u + A(x,t,\partial_x)u = f(x,t,u,\nabla_x u) && \text{a.e. in } \Omega \times]t_1, t_2[, \\ &u(x,t) = 0 && \text{on } \partial\Omega \times [t_1, t_2]. \end{aligned}$$

- A *solution of* (2.10) *in* $\overline{\Omega} \times J$, where J is a noncompact interval having endpoints t_1, t_2 with $-\infty \leqslant t_1 < t_2 \leqslant +\infty$, is a function u such that, for every compact interval $K \subset J$, $u|_{\overline{\Omega} \times K}$ is a solution of (2.10) in $\overline{\Omega} \times K$.

REMARK 2.2. In the literature this kind of solutions of (2.10) are usually referred to as *strong* solutions.

DEFINITION 2.2. A solution $u : \overline{\Omega} \times [t_0, \omega[\to \mathbb{R}$ of (2.10) is said *nonextendible* (*to the right of* ω), if either $\omega = +\infty$, or $\omega < +\infty$ and there is no solution $\hat{u}$ of (2.10) in $\overline{\Omega} \times [t_0, \omega]$ such that $\hat{u}|_{\overline{\Omega} \times [t_0, \omega[} = u$.

We now introduce two notions of lower and upper solutions for (2.10) of increasing generality, allowing to the utmost "angles" in the space variables and "jumps" in the time variable.

NOTATION 2.3. For a function $u : \overline{\Omega} \times [t_1, t_2] \to \mathbb{R}$, we write $u|_{\overline{\Omega} \times]t_1, t_2[} \in W_p^{2,1}(\Omega \times]t_1, t_2[)$ if there exists $\widetilde{u} \in W_p^{2,1}(\Omega \times]t_1, t_2[) \cap C^{1,0}(\overline{\Omega} \times [t_1, t_2])$ such that $\widetilde{u} = u$ on $\overline{\Omega} \times]t_1, t_2[$.

DEFINITION 2.4.

- A *regular lower solution of* (2.10) *in* $\overline{\Omega} \times [t_1, t_2]$, with $t_1, t_2 \in \mathbb{R}$ and $t_1 < t_2$, is a function $\alpha : \bar{\Omega} \times [t_1, t_2] \to \mathbb{R}$, such that $\alpha|_{\overline{\Omega} \times]t_1, t_2[} \in W_p^{2,1}(\Omega \times]t_1, t_2[)$,

$$\begin{aligned} &\partial_t \alpha + A(x,t,\partial_x)\alpha \leqslant f(x,t,\alpha,\nabla_x \alpha) && \text{a.e. in } \Omega \times]t_1, t_2[, \\ &\alpha(x,t) \leqslant 0 && \text{on } \partial\Omega \times [t_1, t_2], \end{aligned}$$

and, for every $x \in \overline{\Omega}$,

$$\alpha(x,t_1) \geqslant \lim_{t \to t_1^+} \alpha(x,t), \qquad \alpha(x,t_2) \leqslant \lim_{t \to t_2^-} \alpha(x,t).$$

- A *lower solution of* (2.10) *in* $\overline{\Omega} \times [t_1,t_2]$ is a function $\alpha : \overline{\Omega} \times [t_1,t_2] \to \mathbb{R}$ for which there are points $t_1 = \sigma_0 < \sigma_1 < \cdots < \sigma_h < \sigma_{h+1} < \cdots < \sigma_k = t_2$, such that, for each $h \in \{0,\dots,k-1\}$, $\alpha|_{\bar{\Omega}\times[\sigma_h,\sigma_{h+1}]} = \max_{1 \leqslant i \leqslant m} \alpha_i(x,t)$ in $\overline{\Omega} \times [\sigma_h,\sigma_{h+1}]$, where, for each $i = 1,\dots,m$, α_i is a regular lower solution of (2.10) in $\overline{\Omega} \times [\sigma_h,\sigma_{h+1}]$.
- A *lower solution* (respectively a *regular lower solution*) *of* (2.10) *in* $\overline{\Omega} \times J$, where J is a noncompact interval having endpoints t_1, t_2 with $-\infty \leqslant t_1 < t_2 \leqslant +\infty$, is a function α such that, for every compact interval $K \subset J$, $\alpha|_{\overline{\Omega}\times K}$ is a lower solution (respectively a regular lower solution) of (2.10) in $\overline{\Omega} \times K$.
- A *regular upper solution of* (2.10) *in* $\overline{\Omega} \times [t_1,t_2]$, with $t_1, t_2 \in \mathbb{R}$ and $t_1 < t_2$, is a function $\beta : \overline{\Omega} \times [t_1,t_2] \to \mathbb{R}$ such that $\beta|_{\overline{\Omega}\times]t_1,t_2[} \in W_p^{2,1}(\Omega \times]t_1,t_2[)$,

$$\begin{array}{ll} \partial_t\beta + A(x,t,\partial_x)\beta \geqslant f(x,t,\beta,\nabla_x\beta) & \text{a.e. in } \Omega \times]t_1,t_2[, \\ \beta(x,t) \geqslant 0 & \text{on } \partial\Omega \times [t_1,t_2], \end{array}$$

and, for every $x \in \bar{\Omega}$,

$$\beta(x,t_1) \leqslant \lim_{t \to t_1^+} \beta(x,t), \qquad \beta(x,t_2) \geqslant \lim_{t \to t_2^-} \beta(x,t).$$

- An *upper solution of* (2.10) *in* $\overline{\Omega} \times [t_1,t_2]$ is a function $\beta : \overline{\Omega} \times [t_1,t_2] \to \mathbb{R}$ for which there are points $t_1 = \rho_0 < \rho_1 < \cdots < \rho_h < \rho_{h+1} < \cdots < \rho_l = t_2$, such that, for each $h \in \{0,\dots,l-1\}$, $\beta|_{\overline{\Omega}\times[\rho_h,\rho_{h+1}]} = \min_{1 \leqslant j \leqslant n} \beta_j(x,t)$ in $\overline{\Omega} \times [\rho_h,\rho_{h+1}]$, where, for each $j = 1,\dots,n$, β_j is a regular upper solution of (2.10) in $\bar{\Omega} \times [\rho_h,\rho_{h+1}]$.
- An *upper solution* (respectively a *regular upper solution*) *of* (2.10) *in* $\overline{\Omega} \times J$, where J is a noncompact interval having endpoints t_1, t_2 such that $-\infty \leqslant t_1 < t_2 \leqslant +\infty$, is a function β such that, for every compact interval $K \subset J$, $\beta|_{\overline{\Omega}\times K}$ is an upper solution (respectively a regular upper solution) of (2.10) in $\overline{\Omega} \times K$.

REMARK 2.3. We notice that a regular lower solution α is continuous in $\bar{\Omega} \times]t_1,t_2[$, but it may be discontinuous with respect to t at the endpoints of the interval $[t_1,t_2]$. A similar observation holds for a regular upper solution β.

REMARK 2.4. Whenever a lower solution and an upper solution are simultaneously considered, we can assume, without loss of generality, that the sequences $(\sigma_h)_h$ and $(\rho_h)_h$ coincide.

Orderings

DEFINITION 2.5. Assume (D). Given functions $u, v : \bar{\Omega} \times I \to \mathbb{R}$, with $I \subseteq \mathbb{R}$ an interval, we write

- $u \leqslant v$ if $u(x,t) \leqslant v(x,t)$ in $\bar{\Omega} \times I$;
- $u < v$ if $u \leqslant v$ and $u \neq v$;
- $u \ll v$ if there exists a function $w \in C^{1,0}(\overline{\Omega} \times I)$, with $w(x,t) > 0$ for every $(x,t) \in \Omega \times I$, $w(x,t) = 0$ on $\partial\Omega \times I$ and $\frac{\partial w}{\partial \nu}(x,t) < 0$ on $\partial\Omega \times I$, where $\nu = \nu(x) \in \mathbb{R}^N$ is the unit outer normal to Ω at $x \in \partial\Omega$, such that $u + w \leqslant v$.

DEFINITION 2.6. Given functions $v, w : \overline{\Omega} \times I \to \mathbb{R}$, with $I \subseteq \mathbb{R}$ an interval and $v < w$, we define the *order intervals*

$$[v, w] = \{u : \overline{\Omega} \times I \to \mathbb{R} \mid v \leqslant u \leqslant w\},$$

$$[v, +\infty[= \{u : \overline{\Omega} \times I \to \mathbb{R} \mid v \leqslant u\},$$

$$]-\infty, w] = \{u : \overline{\Omega} \times I \to \mathbb{R} \mid u \leqslant w\}.$$

All these notations, with the same meaning, will be also used for functions defined on $\partial\Omega \times I$, or $\overline{\Omega}$, or $\partial\Omega$.

DEFINITION 2.7. Let $\mathcal{S}$ be a given set of solutions of (2.10).

- We say that a solution z of (2.10), with $z \in \mathcal{S}$, is a *maximal solution of* (2.10) *in* $\mathcal{S}$ (respectively a *minimal solution of* (2.10) *in* $\mathcal{S}$) if there is no solution u of (2.10), with $u \in \mathcal{S}$, such that $u > z$ (respectively $u < z$).
- We say that a solution z of (2.10), with $z \in \mathcal{S}$, is the *maximum solution of* (2.10) *in* $\mathcal{S}$ (respectively the *minimum solution of* (2.10) *in* $\mathcal{S}$) if every solution u of (2.10), with $u \in \mathcal{S}$, is such that $u \leqslant z$ (respectively $u \geqslant z$).

The following elementary statement is related to the properties of the positive cone in $C^{1,0}(\bar{\Omega} \times [t_1, t_2])$ and can be proved repeating almost verbatim the argument of [55, Lemma 3.1].

PROPOSITION 2.1. *Assume* (D) *and let* $t_1, t_2 \in \mathbb{R}$, *with* $t_1 \leqslant t_2$, *be given. Let* $u \in C^{1,0}(\bar{\Omega} \times [t_1, t_2])$ *be such that* $u = 0$ *on* $\partial\Omega \times [t_1, t_2]$ *and* $u \gg 0$. *Then the following conclusions hold*:

(i) *for every* $c \in]0, 1[$, *there exists* $\delta > 0$ *such that, for any* $v \in C^{1,0}(\bar{\Omega} \times [t_1, t_2])$ *with* $v \geqslant 0$ *on* $\partial\Omega \times [t_1, t_2]$, *if* $\|u - v\|_{C^{1,0}(\bar{\Omega} \times [t_1, t_2])} < \delta$ *then* $v \geqslant cu$ *in* $\bar{\Omega} \times [t_1, t_2]$;

(ii) *there exists* $\delta > 0$ *such that, for any* $v \in C^{1,0}(\bar{\Omega} \times [t_1, t_2])$ *with* $v \leqslant 0$ *on* $\partial\Omega \times [t_1, t_2]$, *if* $\|v\|_{C^{1,0}(\bar{\Omega} \times [t_1, t_2])} < \delta$ *then* $v \leqslant u$ *in* $\bar{\Omega} \times [t_1, t_2]$.

REMARK 2.5. Conclusion (ii) of Proposition 2.1 is still valid if $u \geqslant 0$ on $\partial\Omega \times [t_1, t_2]$.

Order norm

Following [7] we introduce the notion of order norm.

DEFINITION 2.8. Assume (D) and let $t_1, t_2 \in \mathbb{R}$, with $t_1 \leqslant t_2$, be given. Fix a function $e \in C^1(\bar{\Omega})$ such that $e(x) > 0$ in Ω, $e(x) = 0$ and $\partial_\nu e(x) < 0$ on $\partial\Omega$, where $\nu = \nu(x)$ is the unit outer normal to Ω at $x \in \partial\Omega$. For any function $u : \overline{\Omega} \times [t_1, t_2] \to \mathbb{R}$, satisfying $u = 0$ on $\partial\Omega \times [t_1, t_2]$, we set

$$\|u\|_e = \inf\bigl\{\lambda > 0 \mid |u| \leqslant \lambda e \text{ in } \overline{\Omega} \times [t_1, t_2]\bigr\} \ (\in [0, +\infty]).$$

REMARK 2.6. There are constants $c_1, c_2 > 0$ such that, for every $u \in C^{1,0}(\overline{\Omega} \times [t_1, t_2])$ satisfying $u = 0$ on $\partial\Omega \times [t_1, t_2]$, $c_1 \|u\|_{L^\infty(\Omega \times]t_1, t_2[)} \leqslant \|u\|_e \leqslant c_2 \|u\|_{C^{1,0}(\overline{\Omega} \times [t_1, t_2])}$.

In the remainder of this section we collect some basic results that will be systematically used in the sequel.

Parabolic maximum principle

The following is a version of the parabolic strong maximum principle, expressed both in the interior and in the boundary forms (see [37] and also [45,83,128,145]).

PROPOSITION 2.2. *Assume* (D) *and* (A). *Let* $t_1, t_2 \in \mathbb{R}$, *with* $t_1 < t_2$, *be fixed and let* $q \in L^\infty(\Omega \times]t_1, t_2[)$ *be such that*

$$a_0(x, t) + q(x, t) \geqslant 0 \quad \textit{a.e. in } \Omega \times]t_1, t_2[.$$

Assume that $u \in W_p^{2,1}(\Omega \times]t_1, t_2[)$, *with* $p > N + 2$, *satisfy*

$$\partial_t u + A(x, t, \partial_x)u + q(x, t)u \geqslant 0 \quad \textit{a.e. in } \Omega \times]t_1, t_2[.$$

Moreover, set $m = \min_{\overline{\Omega} \times [t_1, t_2]} u$ *and suppose that* $m \leqslant 0$. *Then the following conclusions hold*:

(i) *if* m *is attained at* $(x_0, t_0) \in \Omega \times]t_1, t_2]$, *then* $u = m$ *in* $\bar{\Omega} \times [t_1, t_0]$;

(ii) *if* m *is attained at* $(x_0, t_0) \in \partial\Omega \times]t_1, t_2]$ *and* u *is not constant in* $\Omega \times]t_1, t_0]$, *then* $\partial_\mu u(x_0, t_0) < 0$, *where* $\mu \in \mathbb{R}^N$ *is such that* $\mu \cdot \nu > 0$, $\nu = \nu(x_0)$ *being the unit outer normal to* Ω *at* $x_0 \in \partial\Omega$.

REMARK 2.7. In the special case where $m = 0$, Proposition 2.2 remains valid without the assumption $a_0(x, t) + q(x, t) \geqslant 0$ a.e. in $\Omega \times]t_1, t_2[$. Indeed, in that case, as $u \geqslant 0$, we have a.e. in $\Omega \times]t_1, t_2[$

$$\partial_t u + A(x, t, \partial_x)u - a_0(x, t)u + (a_0 + q)^+(x, t)u \geqslant (a_0 + q)^-(x, t)u \geqslant 0$$

and we can apply the previous result.

A generalized Hölder-type continuity

The following result points out a property, shared by all Carathéodory functions, which can be seen as a generalization of the usual Hölder continuity. In spite of its quite elementary character, it will turn out crucial in the sequel.

PROPOSITION 2.3. *Assume that, for some* $p \geqslant 1$, $f : \Omega \times]t_1, t_2[\times \mathbb{R} \times \mathbb{R}^N \to \mathbb{R}$ *satisfies the* L^p*-Carathéodory conditions. Then for each* $\rho > 0$, *there exists a* L^p*-Carathéodory function* $h : \Omega \times]t_1, t_2[\times [-\rho, \rho] \times [-\rho, \rho] \times \mathbb{R}^N \to \mathbb{R}$ *such that*

- (i) *for a.e.* $(x, t) \in \Omega \times]t_1, t_2[$ *and every* $(r, \xi) \in [-\rho, \rho] \times \mathbb{R}^N$, $h(x, t, \cdot, r, \xi) : [-\rho, \rho] \to \mathbb{R}$ *is strictly increasing*;
- (ii) *for a.e.* $(x, t) \in \Omega \times]t_1, t_2[$ *and every* $(s, \xi) \in [-\rho, \rho] \times \mathbb{R}^N$, $h(x, t, s, \cdot, \xi) : [-\rho, \rho] \to \mathbb{R}$ *is strictly decreasing*;
- (iii) *for a.e.* $(x, t) \in \Omega \times]t_1, t_2[$ *and every* $(r, s, \xi) \in [-\rho, \rho] \times [-\rho, \rho] \times \mathbb{R}^N$, $h(x, t, s, r, \xi) = -h(x, t, r, s, \xi)$;
- (iv) *for a.e.* $(x, t) \in \Omega \times]t_1, t_2[$ *and every* $(r, s, \xi) \in [-\rho, \rho] \times [-\rho, \rho] \times \mathbb{R}^N$, *with* $r < s$,

$$\left| f(x, t, s, \xi) - f(x, t, r, \xi) \right| < h(x, t, s, r, \xi);$$

- (v) *if, moreover, there exist* $K > 0$ *and* $k \in L^p(\Omega \times]t_1, t_2[)$ *such that for a.e.* $(x, t) \in \Omega \times]t_1, t_2[$, *every* $s \in [-\rho, \rho]$ *and every* $\xi \in \mathbb{R}^N$,

$$\left| f(x, t, s, \xi) \right| \leqslant k(x, t) + K|\xi|^2,$$

then, for a.e. $(x, t) \in \Omega \times]t_1, t_2[$, *every* $(r, s) \in [-\rho, \rho] \times [-\rho, \rho]$ *and every* $\xi \in \mathbb{R}^N$,

$$\left| h(x, t, s, r, \xi) \right| \leqslant 2\left(k(x, t) + \rho + K|\xi|^2 \right).$$

PROOF. The function h will be constructed by using the modulus of continuity ω of f. We start by showing that ω is a continuous function.

Step 1. *Let* $g : [a, b] \to \mathbb{R}$ *be a continuous function and let* $\omega : [0, +\infty[\to [0, +\infty[$ *be the modulus of continuity of* g, *defined by setting, for every* $\delta \geqslant 0$,

$$\omega(\delta) = \max_{|x-y| \leqslant \delta} \left| g(x) - g(y) \right|.$$

Then ω *is a continuous function on* $[0, +\infty[$. Clearly, ω is increasing on $[0, +\infty[$ and is continuous at 0 with $\omega(0) = 0$. Let us prove that ω is continuous at any point $\delta_0 > 0$. Fix such a $\delta_0 > 0$. By monotonicity, we have $\lim_{\delta \to \delta_0^-} \omega(\delta) \leqslant \omega(\delta_0) \leqslant \lim_{\delta \to \delta_0^+} \omega(\delta)$. To show that $\lim_{\delta \to \delta_0^+} \omega(\delta) \leqslant \omega(\delta_0)$, pick a decreasing sequence $(\delta_n)_n$ such that $\delta_n \to \delta_0$. For each n, let $x_n, y_n \in [a, b]$ be such that $|x_n - y_n| \leqslant \delta_n$ and $|g(x_n) - g(y_n)| = \omega(\delta_n)$. Possibly passing to subsequences, we may assume $x_n \to \bar{x}$ and $y_n \to \bar{y}$, so that

$$\omega(\delta_n) = \left| g(x_n) - g(y_n) \right| \to \left| g(\bar{x}) - g(\bar{y}) \right| \leqslant \omega(\delta_0)$$

and therefore $\lim_{\delta \to \delta_0^+} \omega(\delta) = \lim_{n \to +\infty} \omega(\delta_n) \leqslant \omega(\delta_0)$. To show that $\lim_{\delta \to \delta_0^-} \omega(\delta) \geqslant \omega(\delta_0)$, let $x_0, y_0 \in [a, b]$ be such that $|x_0 - y_0| \leqslant \delta_0$ and $|g(x_0) - g(y_0)| = \omega(\delta_0)$. Pick an increasing sequence $(\delta_n)_n$ such that $\delta_n \to \delta_0$. By convexity, there exist sequences $(x_n)_n$ and $(y_n)_n$ such that $x_n \to x_0$, $y_n \to y_0$ and $|x_n - y_n| \leqslant \delta_n$, for each n. Hence it follows that

$$\omega(\delta_0) = \bigl|g(x_0) - g(y_0)\bigr| = \lim_{n\to+\infty} \bigl|g(x_n) - g(y_n)\bigr| \leqslant \lim_{n\to+\infty} \omega(\delta_n) = \lim_{\delta\to\delta_0^-} \omega(\delta).$$

Step 2. *Let* $g : [a, b] \times \mathbb{R}^N \to \mathbb{R}$ *be a continuous function and let* $\omega : [0, +\infty[\times \mathbb{R}^N \to [0, +\infty[$ *be the modulus of continuity of* g *with respect to the first variable, defined by setting, for each* $\delta \geqslant 0$ *and* $\xi \in \mathbb{R}^N$,

$$\omega(\delta, \xi) = \max_{|x-y|\leqslant\delta} \bigl|g(x, \xi) - g(y, \xi)\bigr|.$$

Then ω *is a continuous function in* $[0, +\infty[\times \mathbb{R}^N$. Assume, by contradiction, that ω is not continuous at $(\delta_0, \xi_0) \in [0, +\infty[\times \mathbb{R}^N$. Then there exist $\varepsilon > 0$ and, for each $\eta > 0$, a point $(\delta_\eta, \xi_\eta) \in [0, +\infty[\times \mathbb{R}^N$ such that $|\delta_0 - \delta_\eta| + |\xi_0 - \xi_\eta| < \eta$ and $|\omega(\delta_0, \xi_0) - \omega(\delta_\eta, \xi_\eta)| > \varepsilon$. By Step 1, there is $\eta_1 > 0$ such that, if $|\delta_0 - \delta| < \eta_1$, then

$$\bigl|\omega(\delta_0, \xi_0) - \omega(\delta, \xi_0)\bigr| < \varepsilon/2. \tag{2.12}$$

By the continuity of g, there is $\eta_2 > 0$ such that, if $|\xi_0 - \xi| < \eta_2$, then

$$\bigl|g(x, \xi) - g(x, \xi_0)\bigr| < \varepsilon/6$$

for all $x \in [a, b]$. Pick $\eta = \min\{\eta_1, \eta_2\}$ and the corresponding point (δ_η, ξ_η) such that $|\delta_0 - \delta_\eta| + |\xi_0 - \xi_\eta| < \eta$, $|\omega(\delta_0, \xi_0) - \omega(\delta_\eta, \xi_\eta)| > \varepsilon$ and, using (2.12),

$$\bigl|\omega(\delta_\eta, \xi_0) - \omega(\delta_\eta, \xi_\eta)\bigr| > \varepsilon/2.$$

Assume that $\omega(\delta_\eta, \xi_0) > \omega(\delta_\eta, \xi_\eta) + \varepsilon/2$, the other case being similar. Take $x_0, y_0 \in [a, b]$ such that $|x_0 - y_0| \leqslant \delta_\eta$ and

$$\omega(\delta_\eta, \xi_0) = \bigl|g(x_0, \xi_0) - g(y_0, \xi_0)\bigr|.$$

Take further $x_\eta, y_\eta \in [a, b]$ such that $|x_\eta - y_\eta| \leqslant \delta_\eta$ and

$$\omega(\delta_\eta, \xi_\eta) = \bigl|g(x_\eta, \xi_\eta) - g(y_\eta, \xi_\eta)\bigr|.$$

Then we get the contradiction

$$\begin{aligned}
\omega(\delta_\eta, \xi_\eta) &\geqslant \bigl|g(x_0, \xi_\eta) - g(y_0, \xi_\eta)\bigr| \\
&\geqslant \bigl|g(x_0, \xi_0) - g(y_0, \xi_0)\bigr| - \bigl|g(x_0, \xi_0) - g(x_0, \xi_\eta)\bigr| \\
&\quad - \bigl|g(y_0, \xi_0) - g(y_0, \xi_\eta)\bigr| \\
&> \omega(\delta_\eta, \xi_0) - \varepsilon/3 > \omega(\delta_\eta, \xi_\eta) + \varepsilon/6.
\end{aligned}$$

Step 3. *Definition of* h. Fix $\rho > 0$ and set, for a.e. $(x,t) \in \Omega \times]t_1, t_2[$, every $\delta \geqslant 0$ and every $\xi \in \mathbb{R}^N$,

$$\omega(x,t,\delta,\xi) = \max\bigl\{\bigl|f(x,t,r,\xi) - f(x,t,s,\xi)\bigr| \mid |r| \leqslant \rho, |s| \leqslant \rho, |r-s| \leqslant \delta\bigr\}.$$

We have, for a.e. $(x,t) \in \Omega \times]t_1, t_2[$, every $r, s \in [-\rho, \rho]$ with $r \leqslant s$ and $\xi \in \mathbb{R}^N$,

$$\bigl|f(x,t,r,\xi) - f(x,t,s,\xi)\bigr| \leqslant \omega(x,t,s-r,\xi).$$

Let us define for a.e. $(x,t) \in \Omega \times]t_1, t_2[$ and every $r, s \in [-\rho, \rho]$, $\xi \in \mathbb{R}^N$,

$$h(x,t,s,r,\xi) = \operatorname{sgn}(s-r)\bigl(\omega\bigl(x,t,|s-r|,\xi\bigr) + |s-r|\bigr).$$

Then the following conclusions hold:

- for a.e. $(x,t) \in \Omega \times]t_1, t_2[$, $h(x,t,\cdot,\cdot,\cdot)$ is continuous;
- for every $(r,s,\xi) \in [-\rho,\rho] \times [-\rho,\rho] \times \mathbb{R}^N$, $h(\cdot,\cdot,s,r,\xi)$ is measurable (this is due to the fact that $\omega(x,t,\delta,\xi) = \sup\{|f(x,t,r,\xi) - f(x,t,s,\xi)| \mid |r-s| \leqslant \delta$, with $r, s \in \mathbb{Q}\}$);
- for each $\sigma > 0$, there exists $\gamma \in L^p(\Omega \times]t_1, t_2[)$ such that, for a.e. $(x,t) \in \Omega \times]t_1, t_2[$ and every $(r,s,\xi) \in [-\rho,\rho] \times [-\rho,\rho] \times [-\sigma,\sigma]^N$, $|h(x,t,s,r,\xi)| \leqslant \gamma(x,t)$;
- for a.e. $(x,t) \in \Omega \times]t_1, t_2[$ and every $(r,\xi) \in [-\rho,\rho] \times \mathbb{R}^N$, $h(x,t,\cdot,r,\xi) : [-\rho,\rho] \to \mathbb{R}$ is strictly increasing;
- for a.e. $(x,t) \in \Omega \times]t_1, t_2[$ and every $(s,\xi) \in [-\rho,\rho] \times \mathbb{R}^N$, $h(x,t,s,\cdot,\xi) : [-\rho,\rho] \to \mathbb{R}$ is strictly decreasing;
- for a.e. $(x,t) \in \Omega \times]t_1, t_2[$ and every $(r,s,\xi) \in [-\rho,\rho] \times [-\rho,\rho] \times \mathbb{R}^N$, $h(x,t,s,r,\xi) = -h(x,t,r,s,\xi)$;
- for a.e. $(x,t) \in \Omega \times]t_1, t_2[$ and every $(r,s,\xi) \in [-\rho,\rho] \times [-\rho,\rho] \times \mathbb{R}^N$, with $r < s$,

  $$\bigl|f(x,t,s,\xi) - f(x,t,r,\xi)\bigr| < h(x,t,s,r,\xi);$$

- if, moreover, there exist $K > 0$ and $k \in L^p(\Omega \times]t_1, t_2[)$ such that for a.e. $(x,t) \in \Omega \times]t_1, t_2[$, every $s \in [-\rho,\rho]$ and every $\xi \in \mathbb{R}^N$,

  $$\bigl|f(x,t,s,\xi)\bigr| \leqslant k(x,t) + K|\xi|^2,$$

  then, for a.e. $(x,t) \in \Omega \times]t_1, t_2[$, every $(r,s) \in [-\rho,\rho] \times [-\rho,\rho]$ and every $\xi \in \mathbb{R}^N$,

  $$\bigl|h(x,t,s,r,\xi)\bigr| \leqslant 2\bigl(k(x,t) + \rho + K|\xi|^2\bigr). \qquad \Box$$

2.3. *The initial boundary value problem*

Let us consider the parabolic initial value problem

$$\begin{array}{ll} \partial_t u + A(x,t,\partial_x)u = f(x,t,u,\nabla_x u) & \text{in } \Omega \times I, \\ u = 0 & \text{on } \partial\Omega \times I, \\ u(\cdot, t_0) = u_0 & \text{in } \Omega, \end{array} \tag{2.13}$$

where $I \subseteq \mathbb{R}$ is an interval containing a right neighbourhood of t_0 and $u_0 \in W_p^{2-2/p}(\Omega)$ is such that $u_0 = 0$ on $\partial\Omega$.

In this section we collect some basic facts concerning problem (2.13). Namely, we discuss existence, localization and structure of the set of strong solutions of (2.13) in the presence of a pair of possibly nonregular lower and upper solutions.

Solutions and lower and upper solutions

We notice that, assuming (D) and $p > N + 2$, $W_p^{2-2/p}(\Omega)$ is (compactly) embedded in $C^1(\overline{\Omega})$ (see [1, Chapter VII]). Therefore the following definitions make sense.

DEFINITION 2.9. A *solution of* (2.13) in $\overline{\Omega} \times I$, with $I \subseteq \mathbb{R}$ an interval containing a right neighbourhood of t_0, is a solution u of (2.10) in $\overline{\Omega} \times I$ such that

$$u(x, t_0) = u_0(x) \quad \text{in } \overline{\Omega}.$$

The following notion of lower and upper solutions for the initial value problem (2.13) is used.

DEFINITION 2.10.

- A *lower solution* (respectively a *regular lower solution*) *of* (2.13) *in* $\overline{\Omega} \times I$, with $I \subseteq \mathbb{R}$ an interval containing a right neighbourhood of t_0, is a function α which is a lower solution (respectively a regular lower solution) of (2.10) in $\overline{\Omega} \times I$ and satisfies

  $$\alpha(x, t_0) \leqslant u_0(x) \quad \text{in } \Omega.$$

- An *upper solution* (respectively a *regular upper solution*) *of* (2.13) *in* $\overline{\Omega} \times I$, with $I \subseteq \mathbb{R}$ an interval containing a right neighbourhood of t_0, is a function β which is an upper solution (respectively a regular upper solution) of (2.10) in $\overline{\Omega} \times I$ and satisfies

  $$\beta(x, t_0) \geqslant u_0(x) \quad \text{in } \Omega.$$

The linear initial value problem

The next statement, which follows from [80, Chapter IV, Section 9 and Chapter VII, Section 10], regards existence, uniqueness and regularity of solutions of the linear initial value problem

$$\begin{array}{ll} \partial_t u + A(x, t, \partial_x)u = h(x, t) & \text{in } \Omega \times]t_0, \tau[, \\ u = 0 & \text{on } \partial\Omega \times [t_0, \tau], \\ u(\cdot, t_0) = u_0 & \text{in } \Omega. \end{array} \tag{2.14}$$

PROPOSITION 2.4. *Assume* (D) *and* (A). *Fix* $p > N + 2$ *and let* $t_0 \in \mathbb{R}$ *and* $\tau \in]t_0, +\infty[$ *be given. Then for every* $h \in L^p(\Omega \times]t_0, \tau[)$ *and every* $u_0 \in W_p^{2-2/p}(\Omega)$ *with* $u_0 = 0$ *on* $\partial\Omega$, *problem* (2.14) *has a unique solution* $u \in W_p^{2,1}(\Omega \times]t_0, \tau[)$. *Moreover, there exists an increasing function* $C(\tau)$, *which is independent of* h *and* u_0, *such that*

$$\|u\|_{W_p^{2,1}(\Omega \times]t_0, \tau[)} \leqslant C(\tau)\big(\|h\|_{L^p(\Omega \times]t_0, \tau[)} + \|u_0\|_{W_p^{2-2/p}(\Omega)}\big).$$

A Nagumo-type result

The following result will be systematically used in the sequel.

PROPOSITION 2.5. *Assume* (D) *and* (A). *Let* $p > N + 2$, $t_0 \in \mathbb{R}$, $\omega \in \,]t_0, +\infty[$, $h \in L^p(\Omega \times \,]t_0, \omega[)$, $K > 0$ *and* $R > 0$ *be given. Then there exists a constant* $C > 0$ *such that for each* $u : \bar{\Omega} \times [t_0, \omega[\,\to \mathbb{R}$, *with* $u \in W_p^{2,1}(\Omega \times \,]t_0, \tau[)$ *for every* $\tau < \omega$, *satisfying*

$$\begin{array}{ll} \left|\partial_t u + A(x, t, \partial_x)u\right| \leqslant h(x, t) + K|\nabla_x u|^2 & \textit{a.e. in } \Omega \times \,]t_0, \omega[, \\ u = 0 & \textit{on } \partial\Omega \times [t_0, \omega[\end{array}$$

and

$$\left\|u(\cdot, t_0)\right\|_{W_p^{2-2/p}(\Omega)} \leqslant R,$$

we have $u \in W_p^{2,1}(\Omega \times \,]t_0, \omega[)$ *and*

$$\|u\|_{W_p^{2,1}(\Omega \times]t_0, \omega[)} \leqslant C.$$

PROOF. We start with a preliminary result, whose proof closely follows an argument in [6, Lemma 2.1] (see also [149]). We present here a detailed proof in order to verify that the constant γ_0, appearing below, is independent of $\tau \in \,]\delta, \omega[$, whenever $\delta \in \,]t_0, \omega[$ is fixed. Hereafter, for any $\sigma \in \,]t_0, \omega]$, we set $Q_\sigma = \Omega \times \,]t_0, \sigma[$ and $\Sigma_\sigma = \partial\Omega \times [t_0, \sigma[$.

CLAIM. *Fix any constant* $\delta \in \,]t_0, \omega[$. *Let a function* $g \in L^\infty(Q_\omega)$ *and* $u_0 \in W_p^{2-2/p}(\Omega)$ *with* $u_0 = 0$ *on* $\partial\Omega$ *be given. Then, for every* $\tau \in \,]\delta, \omega[$, *the initial value problem*

$$\begin{array}{ll} \partial_t u + A(x, t, \partial_x)u = g(x, t)\big(1 + |\nabla_x u|^2\big) & \text{in } Q_\tau, \\ u = 0 & \text{on } \Sigma_\tau, \\ u(\cdot, t_0) = u_0 & \text{in } \Omega \end{array} \tag{2.15}$$

has a unique solution u, which satisfies

$$\|u\|_{W_p^{2,1}(Q_\tau)} \leqslant \gamma_0\big(\|g\|_{L^\infty(Q_\omega)}, \|u_0\|_{W_p^{2-2/p}(\Omega)}\big),$$

where γ_0 *depends in an increasing way on the indicated quantities, but is independent of* $\tau \in \,]\delta, \omega[$.

Let us consider, for $\tau \in \,]t_0, \omega[$ and $\lambda \in [0, 1]$, the initial value problem

$$\begin{array}{ll} \partial_t u + A(x, t, \partial_x)u = g(x, t)\big(\lambda + |\nabla_x u|^2\big) & \text{in } Q_\tau, \\ u = 0 & \text{on } \Sigma_\tau, \\ u(\cdot, t_0) = \lambda u_0 & \text{in } \Omega. \end{array} \tag{2.16}$$

Step 1. *For every* $\tau \in \,]t_0, \omega[$ *and* $\lambda \in [0, 1]$, (2.16) *has at most one solution*. Indeed, if u, v are solutions of (2.16), then $w = u - v$ satisfies

$$\begin{array}{ll} \partial_t w + A(x,t,\partial_x)w - g\nabla_x(u+v)\cdot\nabla_x w = 0 & \text{in } Q_\tau, \\ w = 0 & \text{on } \Sigma_\tau, \\ w(\cdot,t_0) = 0 & \text{in } \Omega \end{array}$$

and hence $w = 0$, as it easily follows from Proposition 2.2.

For each $\tau \in]t_0, \omega[$, let us denote by Λ_τ the set of all $\lambda \in [0,1]$ such that (2.16) has a solution.

Step 2. There exists a constant $\varepsilon = \varepsilon(\|g\|_{L^\infty(Q_\omega)}, \|u_0\|_{W_p^{2-2/p}(\Omega)}) > 0$ *such that, for every* $\tau \in]t_0, \omega[$ *and* $\lambda_1, \lambda_2 \in \Lambda_\tau$, *with* $|\lambda_1 - \lambda_2| \leqslant \varepsilon$, *the corresponding solutions* u_1, u_2 *of* (2.16) *satisfy*

$$\|u_1 - u_2\|_{W_p^{2,1}(Q_\tau)} \leqslant \gamma_1\big(\|g\|_{L^\infty(Q_\omega)}, \|u_0\|_{W_p^{2-2/p}(\Omega)}, \|u_1\|_{C^{1,0}(\overline{Q}_\tau)}\big), \tag{2.17}$$

where γ_1 *depends in an increasing way on the indicated quantities.* Set $w = u_1 - u_2$ and observe that w satisfies

$$\begin{array}{ll} \partial_t w + A(x,t,\partial_x)w = g\nabla_x(u_1+u_2)\cdot\nabla_x w + (\lambda_1-\lambda_2)g & \text{in } Q_\tau, \\ w = 0 & \text{on } \Sigma_\tau, \\ w(\cdot,t_0) = (\lambda_1-\lambda_2)u_0 & \text{in } \Omega. \end{array} \tag{2.18}$$

Let $\eta = \min\{1, \operatorname{ess\,inf}_{\Omega\times\mathbb{R}} a_0\} > 0$ and define

$$M = \eta^{-1}|\lambda_1 - \lambda_2| \max\big\{\|g\|_{L^\infty(Q_\tau)}, \|u_0\|_{L^\infty(\Omega)}\big\}.$$

The function $M - w$ satisfies

$$\begin{array}{ll} \multicolumn{2}{l}{\partial_t(M-w) + A(x,t,\partial_x)(M-w) - g\nabla_x(u_1+u_2)\cdot\nabla_x(M-w)} \\ \quad = a_0 M - (\lambda_1-\lambda_2)g \geqslant 0 & \text{in } Q_\tau, \\ M - w \geqslant 0 & \text{on } \Sigma_\tau, \\ M - w(\cdot,t_0) = M - (\lambda_1-\lambda_2)u_0 \geqslant 0 & \text{in } \Omega. \end{array}$$

Proposition 2.2 then implies that $M - w \geqslant 0$ in Q_τ. Similarly, one proves that $M + w \geqslant 0$ in Q_τ and hence

$$\|w\|_{L^\infty(Q_\tau)} \leqslant \eta^{-1}|\lambda_1 - \lambda_2| \max\big\{\|g\|_{L^\infty(Q_\tau)}, \|u_0\|_{L^\infty(\Omega)}\big\}. \tag{2.19}$$

Next, using the inequality

$$\big|\nabla_x(u_1+u_2)\cdot\nabla_x w\big| \leqslant |\nabla_x u_1|^2 + 2|\nabla_x w|^2,$$

we get from (2.18)

$$\big\|\partial_t w + A(x,t,\partial_x)w\big\|_{L^p(Q_\tau)}$$

$$\leqslant 2\|g\|_{L^\infty(Q_\tau)}\big\||\nabla_x w|^2\big\|_{L^p(Q_\tau)} \\ + \big(\mathrm{meas}(Q_\tau)\big)^{1/p}\|g\|_{L^\infty(Q_\tau)}\big[\|u_1\|^2_{C^{1,0}(\overline{Q}_\tau)} + 1\big]. \tag{2.20}$$

Now, by Hölder inequality and Fubini theorem, we have

$$\begin{aligned}\big\||\nabla_x w|^2\big\|_{L^p(Q_\tau)} &\leqslant \sum_{i=1}^N \big\||\partial_{x_i} w|^2\big\|_{L^p(Q_\tau)} \\ &= \sum_{i=1}^N \bigg(\int_0^\tau \bigg(\int_\Omega \big|\partial_{x_i} w(x,t)\big|^{2p}\,\mathrm{d}x\bigg)\,\mathrm{d}t\bigg)^{1/p} \\ &= \sum_{i=1}^N \bigg(\int_0^\tau \big(\big\|\partial_{x_i} w(\cdot,t)\big\|^2_{L^{2p}(\Omega)}\big)^p\,\mathrm{d}t\bigg)^{1/p}\end{aligned}$$

and hence, by an interpolation inequality [51, Theorem 1.10.1],

$$\begin{aligned}\big\||\nabla_x w|^2\big\|_{L^p(Q_\tau)} &\leqslant \sum_{i=1}^N \bigg(\int_0^\tau \big(\big\|\partial_{x_i} w(\cdot,t)\big\|^2_{L^{2p}(\Omega)}\big)^p\,\mathrm{d}t\bigg)^{1/p} \\ &\leqslant \sum_{i=1}^N \bigg(\int_0^\tau C_1^p \big\|w(\cdot,t)\big\|^p_{W^2_p(\Omega)}\big\|w(\cdot,t)\big\|^p_{L^\infty(\Omega)}\,\mathrm{d}t\bigg)^{1/p} \\ &\leqslant NC_1\|w\|_{L^\infty(Q_\tau)}\bigg(\int_0^\tau \|w(\cdot,t)\|^p_{W^2_p(\Omega)}\,\mathrm{d}t\bigg)^{1/p} \\ &\leqslant NC_1\|w\|_{L^\infty(Q_\tau)}\|w\|_{W^{2,1}_p(Q_\tau)},\end{aligned} \tag{2.21}$$

where C_1 is a constant depending only on Ω and p. Combining (2.21) with (2.19) yields

$$\big\||\nabla_x w|^2\big\|_{L^p(Q_\tau)} \leqslant \frac{NC_1}{\eta}|\lambda_1 - \lambda_2|\max\big\{\|g\|_{L^\infty(Q_\tau)}, \|u_0\|_{L^\infty(\Omega)}\big\}\|w\|_{W^{2,1}_p(Q_\tau)} \tag{2.22}$$

and hence, inserting (2.22) into (2.20),

$$\begin{aligned}&\big\|\partial_t w + A(x,t,\partial_x)w\big\|_{L^p(Q_\tau)} \\ &\quad\leqslant \frac{2NC_1}{\eta}\|g\|_{L^\infty(Q_\tau)}|\lambda_1 - \lambda_2|\max\big\{\|g\|_{L^\infty(Q_\tau)}, \|u_0\|_{L^\infty(\Omega)}\big\}\|w\|_{W^{2,1}_p(Q_\tau)} \\ &\qquad + \big(\mathrm{meas}(Q_\tau)\big)^{1/p}\|g\|_{L^\infty(Q_\tau)}\big(\|u_1\|^2_{C^{1,0}(\overline{Q}_\tau)} + 1\big).\end{aligned} \tag{2.23}$$

On the other hand, Proposition 2.4 implies that

$$\|w\|_{W_p^{2,1}(Q_\tau)} \leqslant C_2(\tau)\big(\big\|\partial_t w + A(x,t,\partial_x)w\big\|_{L^p(Q_\tau)} + |\lambda_1 - \lambda_2|\|u_0\|_{W_p^{2-2/p}(\Omega)}\big), \tag{2.24}$$

where, for every $\tau \in]t_0, \omega[$, $C_2(\tau) \leqslant C_2(\omega) < +\infty$ as $\omega < +\infty$. Therefore, if we set

$$\begin{aligned} &C_3\big(\|g\|_{L^\infty(Q_\omega)}, \|u_0\|_{L^\infty(\Omega)}\big) \\ &\quad = C_2(\omega)2\eta^{-1}NC_1\|g\|_{L^\infty(Q_\omega)}\max\big\{\|g\|_{L^\infty(Q_\omega)}, \|u_0\|_{L^\infty(\Omega)}\big\} \end{aligned} \tag{2.25}$$

and

$$\begin{aligned} &C_4\big(\|g\|_{L^\infty(Q_\omega)}, \|u_0\|_{W_p^{2-2/p}(\Omega)}, \|u_1\|_{C^{1,0}(\overline{Q}_\tau)}\big) \\ &\quad = C_2(\omega)\|u_0\|_{W_p^{2-2/p}(\Omega)} \\ &\qquad + C_2(\omega)\big(\text{meas}(Q_\omega)\big)^{1/p}\|g\|_{L^\infty(Q_\omega)}\big(\|u_1\|^2_{C^{1,0}(\overline{Q}_\tau)} + 1\big), \end{aligned} \tag{2.26}$$

we get

$$\begin{aligned} \|w\|_{W_p^{2,1}(Q_\tau)} \leqslant{}& C_3\big(\|g\|_{L^\infty(Q_\omega)}, \|u_0\|_{L^\infty(\Omega)}\big)|\lambda_1 - \lambda_2|\|w\|_{W_p^{2,1}(Q_\tau)} \\ &+ C_4\big(\|g\|_{L^\infty(Q_\omega)}, \|u_0\|_{W_p^{2-2/p}(\Omega)}, \|u_1\|_{C^{1,0}(\overline{Q}_\tau)}\big). \end{aligned}$$

Accordingly, letting

$$\varepsilon = \varepsilon\big(\|g\|_{L^\infty(Q_\omega)}, \|u_0\|_{L^\infty(\Omega)}\big) = \big[2C_3\big(\|g\|_{L^\infty(Q_\omega)}, \|u_0\|_{L^\infty(\Omega)}\big)\big]^{-1},$$

we conclude that

$$\|w\|_{W_p^{2,1}(Q_\tau)} \leqslant 2C_4\big(\|g\|_{L^\infty(Q_\omega)}, \|u_0\|_{W_p^{2-2/p}(\Omega)}, \|u_1\|_{C^{1,0}(\overline{Q}_\tau)}\big),$$

provided $|\lambda_1 - \lambda_2| \leqslant \varepsilon$. Hence (2.17) follows setting

$$\begin{aligned} &\gamma_1\big(\|g\|_{L^\infty(Q_\omega)}, \|u_0\|_{W_p^{2-2/p}(\Omega)}, \|u_1\|_{C^{1,0}(\overline{Q}_\tau)}\big) \\ &\quad = 2C_4\big(\|g\|_{L^\infty(Q_\omega)}, \|u_0\|_{W_p^{2-2/p}(\Omega)}, \|u_1\|_{C^{1,0}(\overline{Q}_\tau)}\big), \end{aligned}$$

where γ_1 depends in an increasing way on the indicated quantities.

Step 3. *For every* $\tau \in]t_0, \omega[$ *and* $\lambda \in [0, \varepsilon]$, *the initial value problem* (2.16) *has a solution* u_λ, *which is unique by Step* 1 *and satisfies*

$$\|u_\lambda\|_{W_p^{2,1}(Q_\tau)} \leqslant \gamma_1\big(\|g\|_{L^\infty(Q_\omega)}, \|u_0\|_{W_p^{2-2/p}(\Omega)}, 0\big).$$

For each $\tau \in]t_0, \omega[$, $0 \in \Lambda_\tau$ and for every $\lambda \in [0, \varepsilon]$, any possible solution u_λ of (2.16) satisfies, by letting $u_1 = 0$ and $u_2 = u_\lambda$ in (2.17),

$$\|u_\lambda\|_{C^{1,0}(\overline{Q}_\tau)} < R(\tau) = C_5(\tau)\gamma_1\big(\|g\|_{L^\infty(Q_\omega)}, \|u_0\|_{W_p^{2-2/p}(\Omega)}, 0\big) + 1,$$

where $C_5(\tau)$ is the embedding constant of $W_p^{2,1}(Q_\tau)$ into $C^{1,0}(\overline{Q}_\tau)$. Therefore, the homotopy invariance of the degree implies that

$$\deg\big(I - S_{\tau,\lambda}, B\big(0, R(\tau)\big)\big) = \deg\big(I - S_{\tau,0}, B\big(0, R(\tau)\big)\big),$$

where $S_{\tau,\lambda} : C^{1,0}(\overline{Q}_\tau) \to C^{1,0}(\overline{Q}_\tau)$ is the solution operator associated with (2.16) and $B(0, R(\tau))$ is the open ball in $C^{1,0}(\overline{Q}_\tau)$ of center 0 and radius $R(\tau)$. As for $\mu \in [0, 1]$, $u = \mu S_{\tau,0} u$ has only the trivial solution, we have also

$$\begin{aligned}\deg\big(I - S_{\tau,0}, B\big(0, R(\tau)\big)\big) &= \deg\big(I - \mu S_{\tau,0}, B\big(0, R(\tau)\big)\big)\\ &= \deg\big(I, B\big(0, R(\tau)\big)\big) = 1,\end{aligned}$$

and hence

$$\deg\big(I - S_{\tau,\lambda}, B\big(0, R(\tau)\big)\big) = 1.$$

The existence property of the degree yields the conclusion.

Conclusion. Now, arguing as in Step 3, letting in (2.17) $u_1 = u_\varepsilon$ and $u_2 = u_\lambda$ with $\lambda \in [\varepsilon, \min\{2\varepsilon, 1\}]$, we get $[0, \min\{2\varepsilon, 1\}] \subseteq \Lambda_\tau$ and

$$\|u_{2\varepsilon}\|_{W_p^{2,1}(Q_\tau)} \leqslant 2\gamma_1\big(\|g\|_{L^\infty(Q_\omega)}, \|u_0\|_{W_p^{2-2/p}(\Omega)}, \|u_\varepsilon\|_{C^{1,0}(\overline{Q}_\tau)}\big),$$

where

$$\|u_\varepsilon\|_{C^{1,0}(\overline{Q}_\tau)} \leqslant C_5(\delta, \omega)\gamma_1\big(\|g\|_{L^\infty(Q_\omega)}, \|u_0\|_{W_p^{2-2/p}(\Omega)}, 0\big),$$

$C_5(\delta, \omega)$ denoting a constant such that $C_5(\delta, \omega) > C_5(\tau)$ for every $\tau \in [\delta, \omega]$ (cf. [80, Lemma II.3.3]). Finally, iterating this process a finite number of times, the assertion of the claim follows.

We are now in position to conclude the proof of this proposition. Let $u : \overline{\Omega} \times [t_0, \omega[\to \mathbb{R}$ be a function such that $u \in W_p^{2,1}(Q_\tau)$ for every $\tau \in]t_0, \omega[$, and

$$\begin{aligned}&\big|\partial_t u + A(x, t, \partial_x)u\big| \leqslant h(x, t) + K|\nabla_x u|^2 && \text{a.e. in } Q_\omega,\\ &u = 0 && \text{on } \Sigma_\omega,\\ &u(\cdot, t_0) = u_0 && \text{in } \Omega,\end{aligned}$$

where $u_0 \in W_p^{2-2/p}(\Omega)$ is such that $u_0 = 0$ on $\partial\Omega$ and

$$\|u_0\|_{W_p^{2-2/p}(\Omega)} \leqslant R.$$

Define $k = \frac{\partial_t u + A(x,t,\partial_x)u}{1+h+K|\nabla_x u|^2} \in L^\infty(Q_\omega)$. Let $v \in W_p^{2,1}(Q_\omega)$ be the solution of

$$\begin{array}{ll} \partial_t v + A(x,t,\partial_x)v = k(x,t)h(x,t) & \text{in } Q_\omega, \\ v = 0 & \text{on } \Sigma_\omega, \\ v(\cdot, t_0) = 0 & \text{in } \Omega, \end{array}$$

which satisfies, by Proposition 2.4,

$$\|v\|_{W_p^{2,1}(Q_\omega)} \leqslant C_2(\omega)\|h\|_{L^p(Q_\omega)} \tag{2.27}$$

and hence, by the embedding of $W_p^{2,1}(Q_\omega)$ into $C^{1,0}(\overline{Q}_\omega)$,

$$\|v\|_{C^{1,0}(\overline{Q}_\omega)} \leqslant C_6\|h\|_{L^p(Q_\omega)}. \tag{2.28}$$

Set $w = u - v$ and $g = k\frac{1+K|\nabla_x u|^2}{1+|\nabla_x w|^2}$. The function w satisfies

$$\partial_t w + A(x,t,\partial_x)w = k(x,t)\big(1 + K|\nabla_x u|^2\big) = g(x,t)\big(1 + |\nabla_x w|^2\big)$$

a.e. in Q_ω and therefore, for every $\tau \in]0, \omega[$, it is a solution of

$$\begin{array}{ll} \partial_t w + A(x,t,\partial_x)w = g(x,t)\big(1 + |\nabla_x w|^2\big) & \text{in } Q_\tau, \\ w = 0 & \text{on } \Sigma_\tau, \\ w(\cdot, t_0) = u_0 & \text{in } \Omega. \end{array}$$

Since, by (2.28),

$$\|\nabla_x u\|^2_{L^\infty(Q_\omega)} \leqslant 2\|\nabla_x w\|^2_{L^\infty(Q_\omega)} + 2\big(C_6\|h\|_{L^p(Q_\omega)}\big)^2,$$

it follows that $g \in L^\infty(Q_\omega)$ and

$$\|g\|_{L^\infty(Q_\omega)} \leqslant \max\{1, 2K\} + 2K\big(C_6\|h\|_{L^p(Q_\omega)}\big)^2.$$

Therefore, if we fix $\delta \in]t_0, \omega[$, the above claim implies that, for every $\tau \in]\delta, \omega[$,

$$\|w\|_{W_p^{2,1}(Q_\tau)} \leqslant \gamma_0\Big(\max\{1, 2K\} + 2K\big(C_6\|h\|_{L^p(Q_\omega)}\big)^2, R\Big),$$

which, in turn, yields

$$\|w\|_{C^{1,0}(\overline{Q}_\tau)} \leqslant C_5(\delta, \omega)\gamma_0\Big(\max\{1, 2K\} + 2K\big(C_6\|h\|_{L^p(Q_\omega)}\big)^2, R\Big)$$

and, in particular,

$$\|\nabla_x w\|_{L^\infty(Q_\omega)} \leqslant C_5(\delta, \omega)\gamma_0\Big(\max\{1, 2K\} + 2K\big(C_6\|h\|_{L^p(Q_\omega)}\big)^2, R\Big).$$

Accordingly, denoting by $z \in W_p^{2,1}(Q_\omega)$ the unique solution of

$$\begin{array}{ll} \partial_t z + A(x,t,\partial_x)z = g(x,t)\big(1+|\nabla_x w|^2\big) & \text{in } Q_\omega, \\ z = 0 & \text{on } \Sigma_\omega, \\ z(\cdot,t_0) = u_0 & \text{in } \Omega, \end{array}$$

we have $w = z$ in $\overline{\Omega} \times [t_0,\omega[$ and hence $w \in W_p^{2,1}(Q_\omega)$. Finally, using (2.27), we conclude that $u \in W_p^{2,1}(Q_\omega)$ and

$$\|u\|_{W_p^{2,1}(Q_\omega)} \leqslant \gamma_0\big(\max\{1,2K\} + 2K\big(C_6\|h\|_{L^p(Q_\omega)}\big)^2, R\big) \\ + C_2(\omega)\|h\|_{L^p(Q_\omega)}. \qquad \square$$

Existence of solutions and the Hukuhara–Kneser property

In this section we extend to strong solutions and nonregular lower and upper solutions some existence and localization results for the initial value problem (2.13) which are well known in the frame of classical solutions. We also describe the topological structure of the solution set, proving the Hukuhara–Kneser property. Since our analysis is performed just assuming that f satisfies the Carathéodory conditions, we get an improvement of results obtained in [76], for f Hölder continuous, and in [81], for f continuous. Our proof, which differs from the standard ones in the approximation method, adapts an idea introduced in [139] dealing with ordinary differential equations.

We first deal with the initial value problem on a compact interval.

THEOREM 2.6. *Assume* (D), (A), (C), (N) *and let* $u_0 \in W_p^{2-2/p}(\Omega)$ *be such that* $u_0 = 0$ *on* $\partial\Omega$. *Let* $t_0, t_1 \in \mathbb{R}$ *be such that* $t_0 < t_1$ *and suppose that* α *is a lower solution and* β *is an upper solution of* (2.13) *in* $\overline{\Omega} \times [t_0,t_1]$, *satisfying* $\alpha \leqslant \beta$. *Then there exist the minimum solution* v *and the maximum solution* w *in* $[\alpha,\beta]$ *of problem* (2.13) *in* $\overline{\Omega} \times [t_0,t_1]$. *Further, the set*

$$\mathcal{K} = \big\{u : \overline{\Omega} \times [t_0,t_1] \to \mathbb{R} \mid u \text{ is a solution of (2.13) with } \alpha \leqslant u \leqslant \beta \\ \text{in } \overline{\Omega} \times [t_0,t_1]\big\}$$

is a continuum, i.e. a compact and connected set, in $C^{1,0}(\overline{\Omega} \times [t_0,t_1])$.

PROOF. The proof is divided into three parts.

Part 1. *Existence of a solution* u *of* (2.13) *in* $\overline{\Omega} \times [t_0,t_1]$, *with* $\alpha \leqslant u \leqslant \beta$. We can assume that the sequences $(\sigma_h)_{0 \leqslant h \leqslant k}$ and $(\rho_h)_{0 \leqslant h \leqslant l}$ coincide. We also notice that, by our definition of lower and upper solutions and the condition $\alpha \leqslant \beta$, there exists a constant $M > 0$ such that $-M \leqslant \alpha(x,t) \leqslant \beta(x,t) \leqslant M$ in $\overline{\Omega} \times [t_0,t_1]$. Hence, by condition (N) and Proposition 2.5, there exists $R > 0$ such that, for every function f satisfying (2.11) and every solution u of (2.13) in $\overline{\Omega} \times [t_0,t_1]$ with $\alpha \leqslant u \leqslant \beta$, we have

$$\|u\|_{C^{1,0}(\overline{\Omega}\times[t_0,t_1])} < R. \tag{2.29}$$

For $h \in \{0, \ldots, k-1\}$, let $\alpha = \max_{1 \leqslant i \leqslant m_h} \alpha_i^{(h)}$ and $\beta = \min_{1 \leqslant j \leqslant n_h} \beta_j^{(h)}$ in $\overline{\Omega} \times]\sigma_h, \sigma_{h+1}[$, with $\alpha_i^{(h)}, \beta_j^{(h)} \in W_p^{2,1}(\Omega \times]\sigma_h, \sigma_{h+1}[) \cap C^{1,0}(\overline{\Omega} \times [\sigma_h, \sigma_{h+1}])$. Take $\overline{R}$ such that

$$\begin{aligned}\overline{R} > R + \max_{0 \leqslant h \leqslant k-1} \Big\{ & \max_{1 \leqslant i \leqslant m_h} \big\| \alpha_i^{(h)} \big\|_{C^{1,0}(\overline{\Omega} \times [\sigma_h, \sigma_{h+1}])}, \\ & \max_{1 \leqslant j \leqslant n_h} \big\| \beta_j^{(h)} \big\|_{C^{1,0}(\overline{\Omega} \times [\sigma_h, \sigma_{h+1}])} \Big\}\end{aligned}$$

and set

$$\bar{f}(x, t, s, \xi) = \begin{cases} f(x, t, s, \xi) & \text{if } |\xi| \leqslant \overline{R}, \\ f\big(x, t, s, \overline{R} \frac{\xi}{|\xi|}\big) & \text{if } |\xi| > \overline{R}, \end{cases}$$

for a.e. $(x, t) \in \Omega \times \mathbb{R}$ and every $(s, \xi) \in \mathbb{R} \times \mathbb{R}^N$. For any given $h \in \{0, \ldots, k-1\}$, we define the functions

$$g_i^{(h)}(x, t, s, \xi) = \begin{cases} \bar{f}\big(x, t, \alpha_i^{(h)}(x, t), \xi\big) + \omega_{1i}^{(h)}\big(x, t, \alpha_i^{(h)}(x, t) - s\big) \\ \qquad\qquad\qquad \text{if } s < \alpha_i^{(h)}(x, t), \\ \bar{f}(x, t, s, \xi) \quad \text{if } s \geqslant \alpha_i^{(h)}(x, t), \end{cases}$$

$$h_j^{(h)}(x, t, s, \xi) = \begin{cases} \bar{f}\big(x, t, \beta_j^{(h)}(x, t), \xi\big) - \omega_{2j}^{(h)}\big(x, t, s - \beta_j^{(h)}(x, t)\big) \\ \qquad\qquad\qquad \text{if } s > \beta_j^{(h)}(x, t), \\ \bar{f}(x, t, s, \xi) \quad \text{if } s \leqslant \beta_j^{(h)}(x, t), \end{cases}$$

where

$$\begin{aligned} \omega_{1i}^{(h)}(x, t, \delta) = \max_{|\xi| \leqslant \delta} \big| & \bar{f}\big(x, t, \alpha_i^{(h)}(x, t), \nabla_x \alpha_i^{(h)}(x, t) + \xi\big) \\ & - \bar{f}\big(x, t, \alpha_i^{(h)}(x, t), \nabla_x \alpha_i^{(h)}(x, t)\big)\big|, \\ \omega_{2j}^{(h)}(x, t, \delta) = \max_{|\xi| \leqslant \delta} \big| & \bar{f}\big(x, t, \beta_j^{(h)}(x, t), \nabla_x \beta_j^{(h)}(x, t) + \xi\big) \\ & - \bar{f}\big(x, t, \beta_j^{(h)}(x, t), \nabla_x \beta_j^{(h)}(x, t)\big)\big|, \end{aligned}$$

for $i \in \{1, \ldots, m_h\}$ and $j \in \{1, \ldots, n_h\}$, and

$$F^{(h)}(x, t, s, \xi) = \begin{cases} \max\limits_{1 \leqslant i \leqslant m_h} g_i^{(h)}(x, t, s, \xi) & \text{if } s \leqslant \alpha(x, t), \\ \bar{f}(x, t, s, \xi) & \text{if } \alpha(x, t) < s < \beta(x, t), \\ \min\limits_{1 \leqslant j \leqslant n_h} h_j^{(h)}(x, t, s, \xi) & \text{if } s \geqslant \beta(x, t), \end{cases} \tag{2.30}$$

for a.e. $(x,t) \in \Omega \times]\sigma_h, \sigma_{h+1}[$ and every $(s,\xi) \in \mathbb{R} \times \mathbb{R}^N$. Then we consider the modified problem

$$\begin{array}{ll} \partial_t u + A(x,t,\partial_x)u = F(x,t,u,\nabla_x u) & \text{in } \Omega \times]t_0, t_1[, \\ u = 0 & \text{on } \partial\Omega \times [t_0, t_1], \\ u(\cdot, t_0) = u_0 & \text{in } \Omega, \end{array} \tag{2.31}$$

where $F : \Omega \times]t_0, t_1[\times \mathbb{R} \times \mathbb{R}^N$ is a L^p-Carathéodory function such that, for each $h \in \{0, \ldots, k-1\}$,

$$F(x,t,s,\xi) = F^{(h)}(x,t,s,\xi),$$

for a.e. $(x,t) \in \Omega \times]\sigma_h, \sigma_{h+1}[$ and every $(s,\xi) \in \mathbb{R} \times \mathbb{R}^N$. Notice that there exists $\gamma \in L^p(\Omega \times]t_0, t_1[)$ such that

$$\left|F(x,t,s,\xi)\right| \leqslant \gamma(x,t) \tag{2.32}$$

for a.e. $(x,t) \in \Omega \times]t_0, t_1[$ and every $(s,\xi) \in \mathbb{R} \times \mathbb{R}^N$.

Step 1. *Every solution u of* (2.31) *satisfies $\alpha \leqslant u \leqslant \beta$.* Assume there is a solution u of (2.31) such that $\inf_{\Omega \times]t_0, t_1[}(u - \alpha) < 0$. By our definition of a lower solution of (2.31), we can find $h \in \{0, \ldots, k-1\}$ such that $\inf_{\Omega \times]\sigma_h, \sigma_{h+1}[}(u - \alpha) < 0$ and $u(x, \sigma_h) \geqslant \lim_{t \to \sigma_h^+} \alpha(x,t)$ in Ω. Since $\alpha = \max_{1 \leqslant i \leqslant m_h} \alpha_i^{(h)}$, there is $i \in \{1, \ldots, m_h\}$ such that, setting $v = u - \alpha_i^{(h)} \in W_p^{2,1}(\Omega \times]\sigma_h, \sigma_{h+1}[)$, we have $\min_{\overline{\Omega} \times [\sigma_h, \sigma_{h+1}]} v < 0$, $v(x, \sigma_h) \geqslant 0$ in Ω and $v(x,t) \geqslant 0$ on $\partial\Omega \times [\sigma_h, \sigma_{h+1}]$. Hence there exists $(\bar{x}, \bar{t}) \in \Omega \times]\sigma_h, \sigma_{h+1}]$ such that $\min_{\overline{\Omega} \times [\sigma_h, \sigma_{h+1}]} v = v(\bar{x}, \bar{t})$. As $\bar{x} \in \Omega$, we have $\nabla_x v(\bar{x}, \bar{t}) = 0$ and there is an open ball $B \subseteq \Omega$, with $\bar{x} \in B$, and a point $t_1 \in]\sigma_h, \bar{t}[$ such that, a.e. in $B \times]t_1, \bar{t}]$, $|\nabla_x v(x,t)| \leqslant |v(x,t)|$, $v(x,t) < 0$ and

$$\begin{aligned} &\partial_t v + A(x,t,\partial_x)v \\ &\quad \geqslant F^{(h)}\big(x,t,u(x,t),\nabla_x u(x,t)\big) - f\big(x,t,\alpha_i^{(h)}(x,t),\nabla_x \alpha_i^{(h)}(x,t)\big) \\ &\quad \geqslant \bar{f}\big(x,t,\alpha_i^{(h)}(x,t),\nabla_x u(x,t)\big) + \omega_{1i}^{(h)}\big(x,t,\alpha_i^{(h)}(x,t) - u(x,t)\big) \\ &\qquad - \bar{f}\big(x,t,\alpha_i^{(h)}(x,t),\nabla_x \alpha_i^{(h)}(x,t)\big) \\ &\quad \geqslant -\omega_{1i}^{(h)}\big(x,t,\left|\nabla_x v(x,t)\right|\big) + \omega_{1i}^{(h)}\big(x,t,\left|v(x,t)\right|\big) \\ &\quad \geqslant 0, \end{aligned}$$

because $\omega_{1i}^{(h)}(x,t,\cdot)$ is increasing. Hence Proposition 2.2 implies that $v(x,t) = v(\bar{x}, \bar{t}) = \min_{\overline{\Omega} \times [\sigma_h, \sigma_{h+1}]} v$ in $B \times]t_1, \bar{t}]$ and, as $\operatorname{ess\,inf} a_0 > 0$,

$$\partial_t v + A(x,t,\partial_x)v = a_0 v < 0,$$

a.e. in $B \times]t_1, \bar{t}]$, thus contradicting the previous inequality. Therefore, we conclude that $u \geqslant \alpha$. Similarly, one proves that $u \leqslant \beta$.

Step 2. *Every solution u of* (2.31) *is a solution of* (2.13). In Step 1, we proved that every solution u of (2.31) satisfies $\alpha \leqslant u \leqslant \beta$ and hence it is a solution of

$$\begin{array}{ll} \partial_t u + A(x,t,\partial_x)u = \bar{f}(x,t,u,\nabla_x u) & \text{in } \Omega \times]t_0,t_1[, \\ u = 0 & \text{on } \partial\Omega \times [t_0,t_1], \\ u(\cdot,t_0) = u_0 & \text{in } \Omega. \end{array}$$

As $\bar{f}$ satisfies (2.11), we have $\|u\|_{C^{1,0}(\overline{\Omega}\times[t_0,t_1])} < \overline{R}$ and hence u is a solution of (2.13).

Step 3. *Problem* (2.31) *has at least one solution*. Let us consider the solution operator $S : C^{1,0}(\overline{\Omega} \times [t_0,t_1]) \to C^{1,0}(\overline{\Omega} \times [t_0,t_1])$ associated with (2.31), which sends any function $u \in C^{1,0}(\overline{\Omega} \times [t_0,t_1])$ onto the unique solution $v \in W_p^{2,1}(\overline{\Omega} \times [t_0,t_1])$ of

$$\begin{array}{ll} \partial_t v + A(x,t,\partial_x)v = F(x,t,u,\nabla_x u) & \text{in } \Omega \times]t_0,t_1[, \\ v = 0 & \text{on } \partial\Omega \times [t_0,t_1], \\ v(\cdot,t_0) = u_0 & \text{in } \Omega. \end{array}$$

The operator S is continuous, has a relatively compact range and its fixed points are the solutions of (2.31). In particular, there exists a constant $\widetilde{R} > 0$ such that

$$\|Su\|_{C^{1,0}(\overline{\Omega}\times[t_0,t_1])} < \widetilde{R}$$

for every $u \in C^{1,0}(\overline{\Omega} \times [t_0,t_1])$. Then standard results of degree theory imply that

$$\deg\bigl(I - S, B\bigl(0,\widetilde{R}\bigr)\bigr) = 1,$$

where I is the identity operator in $C^{1,0}(\overline{\Omega} \times [t_0,t_1])$ and $B(0,\widetilde{R})$ is the open ball of center 0 and radius $\widetilde{R}$ in $C^{1,0}(\overline{\Omega} \times [t_0,t_1])$. Therefore S has a fixed point. By the conclusions of Steps 1 and 2, we get the existence of a solution u of (2.13) in $\overline{\Omega} \times [t_0,t_1]$ satisfying $\alpha \leqslant u \leqslant \beta$.

Part 2. *Existence of extremal solutions*. We know, from Part 1, that the solutions u of (2.13) in $\overline{\Omega} \times [t_0,t_1]$, with $\alpha \leqslant u \leqslant \beta$, are precisely the fixed points of the solution operator S associated with (2.31), i.e.

$$\mathcal{K} = \bigl\{u \in C^{1,0}\bigl(\overline{\Omega} \times [t_0,t_1]\bigr) \mid u = Su\bigr\},$$

and $\mathcal{K}$ is a nonempty compact subset of $C^{1,0}(\overline{\Omega} \times [t_0,t_1])$. Next, for each $u \in \mathcal{K}$, define the closed set $\mathcal{C}_u = \{z \in \mathcal{K} \mid z \leqslant u\}$. The family $\{\mathcal{C}_u \mid u \in \mathcal{K}\}$ has the finite intersection property, as it follows from Part 1 observing that if $u_1, u_2 \in \mathcal{K}$, then $\min\{u_1,u_2\}$ is an upper solution of (2.31) with $\alpha \leqslant \min\{u_1,u_2\}$. By the compactness of $\mathcal{K}$ there exists $v \in \bigcap_{u\in\mathcal{K}} \mathcal{C}_u$; clearly, v is the minimum solution in $[\alpha,\beta]$ of (2.13) in $\overline{\Omega} \times [t_0,t_1]$. The maximum solution w can be found in a similar way.

Part 3. *$\mathcal{K}$ is a continuum.* We know from Part 2 that $\mathcal{K}$ is compact in $C^{1,0}(\bar{\Omega} \times [t_0, t_1])$; we apply [77, Theorem 48.2] or [153, Theorem 13.E] to show that $\mathcal{K}$ is connected too. We already proved in Part 1 that there is $R > 0$ such that

$$\deg\bigl(I - S, B(0, R)\bigr) = 1,$$

where $S : C^{1,0}(\overline{\Omega} \times [t_0, t_1]) \to C^{1,0}(\overline{\Omega} \times [t_0, t_1])$ is the solution operator associated with (2.31). Next, for each $n \geqslant 1$, set $\tau_n = \frac{t_1 - t_0}{n}$ and denote by $S_n : C^{1,0}(\overline{\Omega} \times [t_0, t_1]) \to C^{1,0}(\overline{\Omega} \times [t_0, t_1])$ the operator which sends any function $v \in C^{1,0}(\overline{\Omega} \times [t_0, t_1])$ onto the function $w \in C^{1,0}(\overline{\Omega} \times [t_0, t_1])$ defined by

$$w(x,t) = \begin{cases} u_0^*(x,t) & \text{in } \overline{\Omega} \times [t_0, t_0 + \tau_n], \\ u(x,t) & \text{in } \overline{\Omega} \times]t_0 + \tau_n, t_1], \end{cases}$$

where u_0^* is the solution of

$$\begin{array}{ll} \partial_t u + A(x,t,\partial_x)u = 0 & \text{in } \Omega \times]t_0, t_1[, \\ u = 0 & \text{on } \partial\Omega \times [t_0, t_1], \\ u(\cdot, t_0) = u_0 & \text{in } \Omega \end{array}$$

and u is the solution of

$$\begin{array}{ll} \partial_t u + A(x,t,\partial_x)u & \\ \quad = F\bigl(x, t - \tau_n, v(x, t - \tau_n), \nabla_x v(x, t - \tau_n)\bigr) & \text{in } \Omega \times]t_0 + \tau_n, t_1[, \\ u = 0 & \text{on } \partial\Omega \times [t_0 + \tau_n, t_1], \\ u(\cdot, t_0 + \tau_n) = u_0^*(\cdot, t_0 + \tau_n) & \text{in } \Omega. \end{array} \tag{2.33}$$

Each operator S_n is continuous and has a relatively compact range. Further, $I - S_n$ is one-to-one. Indeed, let $v_1, v_2 \in C^{1,0}(\overline{\Omega} \times [t_0, t_1])$ be such that $(I - S_n)v_1 = (I - S_n)v_2$. This means that $v_1(x,t) = v_2(x,t)$ in $\overline{\Omega} \times [t_0, t_0 + \tau_n]$ and $v_1(x,t) - u_1(x,t) = v_2(x,t) - u_2(x,t)$ in $\bar{\Omega} \times [t_0 + \tau_n, t_1]$, where, for $i = 1, 2$, u_i is the solution of (2.33) corresponding to $v = v_i$. Hence we get by recursion that $u_1(x,t) = u_2(x,t)$ and $v_1(x,t) = v_2(x,t)$ in $\bar{\Omega} \times [t_0 + (k-1)\tau_n, t_0 + k\tau_n]$, for $k = 2, \ldots, n$, and then $u_1(x,t) = u_2(x,t)$ and $v_1(x,t) = v_2(x,t)$ in $\overline{\Omega} \times [t_0 + \tau_n, t_1]$. This yields $v_1 = v_2$.

At last we prove that the sequence $(S_n)_n$ converges to S uniformly in $C^{1,0}(\overline{\Omega} \times [t_0, t_1])$. Assume by contradiction this is false, i.e. there exist a constant $\varepsilon > 0$ and a sequence $(v_k)_k$ in $C^{1,0}(\overline{\Omega} \times [t_0, t_1])$ such that

$$\|S_{n_k} v_k - S v_k\|_{C^{1,0}(\overline{\Omega} \times [t_0, t_1])} \geqslant \varepsilon. \tag{2.34}$$

For each k, define

$$g_k(x,t) = F\bigl(x, t, v_k(x,t), \nabla_x v_k(x,t)\bigr) \quad \text{a.e. in } \Omega \times]t_0, t_1[,$$

and

$$\ell_k(x,t) = \begin{cases} 0 \quad \text{a.e. in } \Omega \times]t_0, t_0 + \tau_{n_k}[, \\ F\big(x, t-\tau_{n_k}, v_k(x, t-\tau_{n_k}), \nabla_x v_k(x, t-\tau_{n_k})\big) \\ \qquad \text{a.e. in } \Omega \times]t_0 + \tau_{n_k}, t_1[. \end{cases}$$

Then $Sv_k = w_k$ is the solution of

$$\begin{array}{ll} \partial_t u + A(x,t,\partial_x)u = g_k(x,t) & \text{in } \Omega \times]t_0, t_1[, \\ u = 0 & \text{on } \partial\Omega \times [t_0, t_1], \\ u(\cdot, t_0) = u_0 & \text{in } \Omega \end{array}$$

and $S_{n_k} v_k = z_k$ is the solution of

$$\begin{array}{ll} \partial_t u + A(x,t,\partial_x)u = \ell_k(x,t) & \text{in } \Omega \times]t_0, t_1[, \\ u = 0 & \text{on } \partial\Omega \times [t_0, t_1], \\ u(\cdot, t_0) = u_0 & \text{in } \Omega. \end{array}$$

By condition (2.32), we can suppose, possibly passing to subsequences, that $(g_k)_k$ converges weakly in $L^p(\Omega \times]t_0, t_1[)$ to g and $(w_k)_k$ converges weakly in $W_p^{2,1}(\Omega \times]t_0, t_1[)$ to the solution w of

$$\begin{array}{ll} \partial_t u + A(x,t,\partial_x)u = g(x,t) & \text{in } \Omega \times]t_0, t_1[, \\ u = 0 & \text{on } \partial\Omega \times [t_0, t_1], \\ u(\cdot, t_0) = u_0 & \text{in } \Omega. \end{array}$$

Similarly, we can suppose that $(\ell_k)_k$ converges weakly in $L^p(\Omega \times]t_0, t_1[)$ to ℓ and $(z_k)_k$ converges weakly in $W_p^{2,1}(\Omega \times]t_0, t_1[)$ to the solution z of

$$\begin{array}{ll} \partial_t u + A(x,t,\partial_x)u = \ell(x,t) & \text{in } \Omega \times]t_0, t_1[, \\ u = 0 & \text{on } \partial\Omega \times [t_0, t_1], \\ u(\cdot, t_0) = u_0 & \text{in } \Omega. \end{array}$$

We shall prove that $g = \ell$. Hence the sequences $(w_k)_k$ and $(z_k)_k$ will have the same limit in $C^{1,0}(\overline{\Omega} \times [t_0, t_1])$, thus contradicting (2.34). For any $k \geqslant 1$ and $\psi \in L^{\frac{p}{p-1}}(\Omega \times]t_0, t_1[)$, let us compute

$$\begin{aligned} &\int_{\Omega \times]t_0, t_1[} \ell_k \psi \\ &\quad = \int_\Omega \left(\int_{t_0+\tau_{n_k}}^{t_1} F\big(x, t-\tau_{n_k}, v_k(x, t-\tau_{n_k}), \nabla_x v_k(x, t-\tau_{n_k})\big) \psi(x,t)\, \mathrm{d}t \right) \mathrm{d}x \\ &\quad = \int_\Omega \left(\int_{t_0}^{t_1-\tau_{n_k}} F\big(x, s, v_k(x,s), \nabla_x v_k(x,s)\big) \psi(x, s+\tau_{n_k})\, \mathrm{d}s \right) \mathrm{d}x \\ &\quad = \int_{\Omega \times]t_0, t_1[} g_k \psi_k, \end{aligned}$$

where we set

$$\psi_k(x,t) = \begin{cases} \psi(x, t+\tau_{n_k}) & \text{a.e. in } \Omega \times \,]t_0, t_1 - \tau_{n_k}[, \\ 0 & \text{a.e. in } \Omega \times [t_1 - \tau_{n_k}, t_1[. \end{cases}$$

Since $(g_k)_k$ is bounded in $L^p(\Omega \times \,]t_0, t_1[)$ and

$$\int_{\Omega\times]t_0,t_1[} \ell_k \psi = \int_{\Omega\times]t_0,t_1[} g_k \psi + \int_{\Omega\times]t_0,t_1[} g_k(\psi_k - \psi),$$

for proving that $g = \ell$ it is enough to show that $\|\psi_k - \psi\|_{L^{\frac{p}{p-1}}(\Omega\times]t_0,t_1[)} \to 0$, as $k \to +\infty$. Let us denote by $\widetilde{\psi}$ the zero extension of ψ outside $\Omega \times \,]t_0, t_1[$ and define

$$\widetilde{\psi}_k(x,t) = \widetilde{\psi}(x, t + \tau_{n_k}) \quad \text{a.e. in } \mathbb{R}^{N+1}.$$

By [22, Lemma IV.4] $(\widetilde{\psi}_k)_k$ converges to $\widetilde{\psi}$ in $L^{\frac{p}{p-1}}(\mathbb{R}^{N+1})$. Hence we obtain

$$\begin{aligned}
&\|\psi_k - \psi\|^{\frac{p}{p-1}}_{L^{\frac{p}{p-1}}(\Omega\times]t_0,t_1[)} \\
&\quad = \int_\Omega \left(\int_{t_0}^{t_1-\tau_{n_k}} \left|\psi_k(x,t) - \psi(x,t)\right|^{\frac{p}{p-1}} \mathrm{d}t \right) \mathrm{d}x \\
&\qquad + \int_\Omega \left(\int_{t_1-\tau_{n_k}}^{t_1} \left|\psi(x,t)\right|^{\frac{p}{p-1}} \mathrm{d}t \right) \mathrm{d}x \\
&\quad = \int_\Omega \left(\int_{\mathbb{R}} \left|\widetilde{\psi}_k(x,t) - \widetilde{\psi}(x,t)\right|^{\frac{p}{p-1}} \mathrm{d}t \right) \mathrm{d}x \\
&\qquad - \int_\Omega \left(\int_{t_0-\tau_{n_k}}^{t_0} \left|\widetilde{\psi}_k(x,t)\right|^{\frac{p}{p-1}} \mathrm{d}t \right) \mathrm{d}x \\
&\quad = \left\|\widetilde{\psi}_k - \widetilde{\psi}\right\|^{\frac{p}{p-1}}_{L^{\frac{p}{p-1}}(\mathbb{R}^{N+1})} - \int_\Omega \left(\int_{t_0}^{\tau_{n_k}+t_0} \left|\widetilde{\psi}(x,t)\right|^{\frac{p}{p-1}} \mathrm{d}t \right) \mathrm{d}x \to 0,
\end{aligned}$$

as $k \to +\infty$. This concludes the proof. □

REMARK 2.8. Condition (N) can be obviously replaced in Theorem 2.6 by

(N′) there exist $h \in L^p(\Omega \times \,]t_0, t_1[)$, with $p > N + 2$, and $K > 0$ such that, for a.e. $(x,t) \in \Omega \times \,]t_0, t_1[$, every $s \in [\alpha(x,t), \beta(x,t)]$ and every $\xi \in \mathbb{R}^N$,

$$\left|f(x,t,s,\xi)\right| \leqslant h(x,t) + K|\xi|^2.$$

According to Proposition 2.5, these Nagumo-type conditions prevent the formation of singularities of the space gradient of locally bounded solutions of (2.13).

Now we extend Theorem 2.6 to noncompact intervals.

COROLLARY 2.7. *Assume* (D), (A), (C), (N) *and let* $u_0 \in W_p^{2-2/p}(\Omega)$ *be such that* $u_0 = 0$ *on* $\partial\Omega$. *Let* $t_0 \in \mathbb{R}$ *and* $\tau \in \,]t_0, +\infty]$. *Suppose that* α *is a lower solution and* β *is an upper solution of* (2.13) *in* $\overline{\Omega} \times [t_0, \tau[$ *satisfying* $\alpha \leqslant \beta$. *Then there exist the minimum solution* v *and the maximum solution* w *in* $[\alpha, \beta]$ *of* (2.13) *in* $\overline{\Omega} \times [t_0, \tau[$. *Further, the set*

$$\mathcal{K} = \big\{u : \overline{\Omega} \times [t_0, \tau[\, \to \mathbb{R} \mid u \text{ is a solution of (2.13) with } \alpha \leqslant u \leqslant \beta\big\}$$

is a continuum in $C^{1,0}(\overline{\Omega} \times [t_0, \tau[)$, *endowed with the topology of* $C^{1,0}$*-convergence on compact subsets of* $\overline{\Omega} \times [t_0, \tau[$.

PROOF. Let $(\tau_n)_n$, with $\tau_0 = t_0$, be a strictly increasing sequence converging to τ.

Step 1. *Existence of extremal solutions.* In order to prove the existence of the minimum solution v in $[\alpha, \beta]$ of (2.13) in $\overline{\Omega} \times [t_0, \tau[$, we apply recursively Theorem 2.6 to (2.13) in $\overline{\Omega} \times [t_0, \tau_n]$ for each $n \geqslant 1$. Let us denote by v_n the minimum solution v in $[\alpha, \beta]$ of (2.13) in $\bar{\Omega} \times [t_0, \tau_n]$. By the minimality of v_n, we have $v_{n+1}|_{\overline{\Omega}\times[t_0,\tau_n]} \geqslant v_n$. On the other hand, $v_n(\cdot, \tau_n) \in W_p^{2-2/p}(\Omega)$, $v_n(\cdot, \tau_n) = 0$ on $\partial\Omega$ and the functions $\alpha|_{\overline{\Omega}\times[\tau_n,\tau_{n+1}]}$ and $v_{n+1}|_{\bar{\Omega}\times[\tau_n,\tau_{n+1}]}$ are, respectively, a lower and an upper solution of the initial value problem

$$\begin{array}{ll}
\partial_t u + A(x, t, \partial_x)u = f(x, t, u, \nabla_x u) & \text{in } \Omega \times \,]\tau_n, \tau_{n+1}[, \\
u = 0 & \text{on } \partial\Omega \times [\tau_n, \tau_{n+1}], \\
u(\cdot, \tau_n) = v_n(\cdot, \tau_n) & \text{in } \Omega.
\end{array}$$

Hence this problem has a solution v_n^* satisfying $\alpha|_{\bar{\Omega}\times[\tau_n,\tau_{n+1}]} \leqslant v_n^* \leqslant v_{n+1}|_{\bar{\Omega}\times[\tau_n,\tau_{n+1}]}$. Then we define $\hat{v}_{n+1} : \bar{\Omega} \times [t_0, \tau_{n+1}] \to \mathbb{R}$ by setting

$$\hat{v}_{n+1}(x, t) = \begin{cases} v_n(x, t) & \text{in } \overline{\Omega} \times [t_0, \tau_n[, \\ v_n^*(x, t) & \text{in } \overline{\Omega} \times [\tau_n, \tau_{n+1}]. \end{cases}$$

Let us prove that $\hat{v}_{n+1} \in W_p^{2,1}(\Omega \times \,]t_0, \tau_{n+1}[)$. Let $w \in W_p^{2,1}(\Omega \times \,]t_0, \tau_{n+1}[)$ be the unique solution of the linear initial value problem

$$\begin{array}{ll}
\partial_t u + A(x, t, \partial_x)u = f(x, t, \hat{v}_{n+1}, \nabla_x \hat{v}_{n+1}) & \text{in } \Omega \times \,]t_0, \tau_{n+1}[, \\
u = 0 & \text{on } \partial\Omega \times [t_0, \tau_{n+1}], \\
u(\cdot, t_0) = u_0 & \text{in } \Omega.
\end{array}$$

Since both v_n and $w|_{\overline{\Omega}\times[t_0,\tau_n]}$ are solutions of the linear initial value problem

$$\begin{array}{ll}
\partial_t u + A(x, t, \partial_x)u = f(x, t, v_n, \nabla_x v_n) & \text{in } \Omega \times \,]t_0, \tau_n[, \\
u = 0 & \text{on } \partial\Omega \times [t_0, \tau_n], \\
u(\cdot, t_0) = u_0 & \text{in } \Omega,
\end{array}$$

by uniqueness, we get $v_n = w$ in $\overline{\Omega} \times [t_0, \tau_n]$. Further, as $w(\cdot, \tau_n) = v_n(\cdot, \tau_n)$ in Ω, v_n^* and $w|_{\overline{\Omega}\times[\tau_n,\tau_{n+1}]}$ are both solutions of the linear initial value problem

$$\begin{array}{ll} \partial_t u + A(x,t,\partial_x)u = f(x,t,v_n^*,\nabla_x v_n^*) & \text{in } \Omega \times]\tau_n, \tau_{n+1}[, \\ u = 0 & \text{on } \partial\Omega \times [\tau_n, \tau_{n+1}], \\ u(\cdot, \tau_n) = v_n(\cdot, \tau_n) & \text{in } \Omega. \end{array}$$

Hence, by uniqueness, we have $v_n^* = w$ in $\overline{\Omega} \times [\tau_n, \tau_{n+1}]$ and we conclude that $\hat{v}_{n+1} = w$ in $\overline{\Omega} \times [t_0, \tau_{n+1}]$. Therefore $\hat{v}_{n+1}$ is a solution of (2.13) in $\overline{\Omega} \times [t_0, \tau_{n+1}]$ satisfying $\alpha \leqslant \hat{v}_{n+1} \leqslant v_{n+1}$. By the minimality of v_{n+1}, we conclude that $\hat{v}_{n+1} = v_{n+1}$ and hence $v_{n+1}|_{\overline{\Omega}\times[t_0,\tau_n]} = v_n$. Then we define $v : \overline{\Omega} \times [t_0, \tau[\to \mathbb{R}$ by setting $v(x,t) = v_n(x,t)$ in $\overline{\Omega} \times [t_0, \tau_n]$. We have that v is the minimum solution in $[\alpha, \beta]$ of (2.13) in $\overline{\Omega} \times [t_0, \tau[$, because, if u were a solution of (2.13) in $\overline{\Omega} \times [t_0, \tau[$ with $u \geqslant \alpha$ and $u \ngeqslant v$, then it should follow $u|_{\overline{\Omega}\times[t_0,\tau_n]} \ngeqslant v_n$ for some n, thus contradicting the minimality of v_n. Similarly, we prove the existence of the maximum solution w in $[\alpha, \beta]$ of (2.13) in $\overline{\Omega} \times [t_0, \tau[$.

Step 2. *$\mathcal{K}$ is a continuum.* We denote by $\mathcal{K}_n$ the set of all solutions $u : \overline{\Omega} \times [t_0, \tau_n] \to \mathbb{R}$ of (2.13) such that $\alpha \leqslant u \leqslant \beta$ on $\overline{\Omega} \times [t_0, \tau_n]$. By Theorem 2.6, $\mathcal{K}_n$ is a continuum in $C^{1,0}(\overline{\Omega} \times [t_0, \tau_n])$. For every $m < n$, let also $\pi_m^n : \mathcal{K}_n \to \mathcal{K}_m$ be the restriction map on $\overline{\Omega} \times [t_0, \tau_m]$, i.e. $\pi_m^n(u) = u|_{\overline{\Omega}\times[t_0,\tau_m]}$ for all $u \in \mathcal{K}_n$. For each $u \in \mathcal{K}$, let us set now $u_n = u|_{\overline{\Omega}\times[t_0,\tau_n]}$ and define a function $\chi : \mathcal{K} \to \prod_{n=1}^{+\infty} \mathcal{K}_n$, by $\chi(u) = (u_n)_n$. Observe that χ is a homeomorphism of $\mathcal{K}$ into $\prod_{n=1}^{+\infty} \mathcal{K}_n$, when $\prod_{n=1}^{+\infty} \mathcal{K}_n$ is endowed with the Tychonoff product topology, and its range $\chi(\mathcal{K})$ is the set of all sequences $(u_n)_n \in \prod_{n=1}^{+\infty} \mathcal{K}_n$ such that, for all $m < n$, $\pi_m^n(u_n) = u_m$, i.e. $\chi(\mathcal{K})$ is the inverse limit of the sequence $(\mathcal{K}_n)_n$ with bonding maps π_m^n (see [47]). As the inverse limit of a sequence of continua is a continuum [47, Theorem 6.1.20] we deduce that $\chi(\mathcal{K})$ is a continuum as well. Since $\mathcal{K}$ is homeomorphic to $\chi(\mathcal{K})$, the conclusion is achieved. □

Continuation and ultimate behaviour of local solutions

The following two results concern existence, continuation and ultimate behaviour of local solutions of problem (2.13); although they are basically known, we provide here simple proofs based on Proposition 2.5 and Theorem 2.6.

LEMMA 2.8. *Assume* (D), (A), (C), (N) *and let* $u_0 \in W_p^{2-2/p}(\Omega)$ *be such that* $u_0 = 0$ *on* $\partial\Omega$. *Fix* $t_0 \in \mathbb{R}$ *and* $t_1 \in]t_0, +\infty]$. *If* α *is a lower solution of* (2.13) *in* $\Omega \times]t_0, t_1[$, *then there exist* $\omega \in]t_0, t_1]$ *and a solution* v *of* (2.13) *in* $\overline{\Omega} \times [t_0, \omega[$, *with* $v \geqslant \alpha$, *such that every upper solution* β *of* (2.13) *in* $\overline{\Omega} \times [t_0, \sigma]$, *with* $\beta \geqslant \alpha$, *satisfies* $\sigma \leqslant \omega$ *and* $\beta \geqslant v$ *in* $\overline{\Omega} \times [t_0, \sigma]$. *Similarly, if* β *is an upper solution of* (2.13) *in* $\Omega \times]t_0, t_1[$, *then there exist* $\omega \in]t_0, t_1]$ *and a solution* w *of* (2.13) *in* $\overline{\Omega} \times [t_0, \omega[$, *with* $w \leqslant \beta$, *such that every lower solution* α *of* (2.13) *in* $\overline{\Omega} \times [t_0, \sigma]$, *with* $\alpha \leqslant \beta$, *satisfies* $\sigma \leqslant \omega$ *and* $\alpha \leqslant w$ *in* $\overline{\Omega} \times [t_0, \sigma]$.

PROOF. The proof is carried out through two steps.

Step 1. *Existence of a local solution $u \geqslant \alpha$.* Let $\alpha = \max_{1\leqslant i\leqslant m} \alpha_i$ in $\overline{\Omega} \times [t_0, \sigma_1]$, where $\sigma_1 > t_0$ comes from the definition of a lower solution. Define, for each $i \in \{1, \dots, m\}$,

$$g_i(x,t,s,\xi) = \begin{cases} f\big(x,t,\alpha_i(x,t),\xi\big) + \omega_i\big(x,t,\alpha_i(x,t) - s\big) & \text{if } s < \alpha_i(x,t), \\ f(x,t,s,\xi) & \text{if } s \geqslant \alpha_i(x,t), \end{cases}$$

where

$$\begin{aligned} &\omega_i(x,t,\delta) \\ &\quad = \max_{|\xi|\leqslant\delta} \big| f\big(x,t,\alpha_i(x,t), \nabla_x\alpha_i(x,t) + \xi\big) - f\big(x,t,\alpha_i(x,t), \nabla_x\alpha_i(x,t)\big)\big| \end{aligned}$$

for a.e. $(x,t) \in \Omega \times]t_0, \sigma_1[$ and every $(s,\xi) \in \mathbb{R} \times \mathbb{R}^N$. Fix a constant

$$R > \max\big\{\|\alpha\|_{L^\infty(\Omega\times]t_0,\sigma_1[)}, \|u_0\|_{L^\infty(\Omega)}\big\}$$

and consider the modified problem

$$\begin{array}{ll} \partial_t u + A(x,t,\partial_x)u = F(x,t,u,\nabla_x u) & \text{in } \Omega \times]t_0,\sigma_1[, \\ u = 0 & \text{on } \partial\Omega \times [t_0,\sigma_1], \\ u(\cdot,t_0) = u_0 & \text{in } \Omega, \end{array} \tag{2.35}$$

where

$$F(x,t,s,\xi) = \begin{cases} \max\limits_{1\leqslant i\leqslant m} g_i(x,t,s,\xi) & \text{if } s \leqslant \alpha(x,t), \\ f(x,t,s,\xi) & \text{if } \alpha(x,t) < s < R, \\ \big(R + 1 - |s|\big) f(x,t,s,\xi) & \text{if } R \leqslant s \leqslant R+1, \\ 0 & \text{if } s > R+1, \end{cases}$$

for a.e. $(x,t) \in \Omega \times]t_0,\sigma_1[$ and every $(s,\xi) \in \mathbb{R} \times \mathbb{R}^N$. Problem (2.35) admits any large positive constant as an upper solution. Therefore, by Theorem 2.6, it has at least one solution, which gives rise to a local solution of (2.13) defined in $\overline{\Omega} \times [t_0, \tau]$, for some $\tau > t_0$.

Step 2. *Existence of ω and v.* Let ω be the supremum of all $\sigma \in]t_0, t_1[$ such that problem (2.13) has a solution u in $\overline{\Omega} \times [t_0, \sigma]$ with $u \geqslant \alpha$. Let $(\sigma_n)_n$ be a strictly increasing sequence converging to ω and $(u_n)_n$ be the corresponding sequence of solutions of (2.13) defined in $\overline{\Omega} \times [t_0, \sigma_n]$ with $u_n \geqslant \alpha$. By Theorem 2.6, for each n, there exists the minimum solution v_n in $[\alpha, u_n]$ of (2.13) in $\overline{\Omega} \times [t_0, \sigma_n]$. As in the proof of Corollary 2.7, we see that the function $v : \overline{\Omega} \times [t_0, \omega[\to \mathbb{R}$, defined by setting $v(x,t) = v_n(x,t)$ in $\overline{\Omega} \times [t_0, \sigma_n]$, is the minimum solution in $[\alpha, +\infty[$ of (2.13) in $\overline{\Omega} \times [t_0, \omega[$. Finally, we notice that every upper solution β of (2.13) in $\overline{\Omega} \times [t_0, \sigma]$, with $\beta \geqslant \alpha$, is such that $\sigma \leqslant \omega$ and $\beta \geqslant v$ in $\overline{\Omega} \times [t_0, \sigma]$. Indeed, there is a solution z of (2.13) in $\overline{\Omega} \times [t_0, \sigma]$, satisfying $\alpha \leqslant z \leqslant \beta$ and hence, by construction of v, $z \geqslant v$ in $\overline{\Omega} \times [t_0, \sigma]$. □

PROPOSITION 2.9. *Assume* (D), (A), (C), (N) *and let $u_0 \in W_p^{2-2/p}(\Omega)$ be such that $u_0 = 0$ on $\partial\Omega$. Then problem* (2.13) *has at least one solution $u : \overline{\Omega} \times [t_0, \tau] \to \mathbb{R}$, for some $\tau > t_0$,* *and every such a solution can be continued to a nonextendible solution. Further every nonextendible solution* $u : \overline{\Omega} \times [t_0, \omega[\to \mathbb{R}$, *with* $\omega < +\infty$, *satisfies*

$$\limsup_{t \to \omega} \|u(\cdot, t)\|_{L^\infty(\Omega)} = +\infty.$$

PROOF. We proceed through three steps.

Step 1. *Existence of local solutions*. We fix a constant $R > \|u_0\|_{L^\infty(\Omega)}$ and we set, for a.e. $(x, t) \in \Omega \times \mathbb{R}$ and every $(s, \xi) \in \mathbb{R} \times \mathbb{R}^N$,

$$F(x,t,s,\xi) = \begin{cases} f(x,t,s,\xi) & \text{if } |s| < R, \\ (R + 1 - |s|) f(x,t,s,\xi) & \text{if } R \leqslant |s| \leqslant R + 1, \\ 0 & \text{if } |s| > R + 1. \end{cases}$$

The corresponding initial value problem

$$\begin{array}{ll} \partial_t u + A(x,t,\partial_x) u = F(x,t,u,\nabla_x u) & \text{in } \Omega \times]t_0, t_0 + 1[, \\ u = 0 & \text{on } \partial\Omega \times [t_0, t_0 + 1], \\ u(\cdot, t_0) = u_0 & \text{in } \Omega, \end{array}$$

admits any large negative constant as a lower solution and any large positive constant as an upper solution. Therefore, by Theorem 2.6, it has a solution, which gives rise to a local solution of (2.13) defined on $\overline{\Omega} \times [t_0, \tau]$, for some $\tau > 0$.

Step 2. *Existence of nonextendible solutions*. Let u be a solution of (2.13) in $\overline{\Omega} \times [t_0, \tau]$, with $\tau \in]t_0, +\infty[$. Consider the set $\mathcal{V}$ of all functions $v : \overline{\Omega} \times [t_0, \rho[\to \mathbb{R}$, for some $\rho > \tau$, such that v is a solution of (2.13) in $\overline{\Omega} \times [t_0, \sigma]$, for every $\sigma < \rho$, and $v|_{\overline{\Omega} \times [t_0, \tau]} = u$. This set $\mathcal{V}$ is non-empty, since $u(\cdot, \tau) \in W_p^{2-2/p}(\Omega)$ and $u(\cdot, \tau) = 0$ on $\partial\Omega$ and therefore u can be locally continued to the right of τ. If $v_1, v_2 \in \mathcal{V}$, we set $v_1 \prec v_2$ whenever $\rho_1 \leqslant \rho_2$ and $v_2|_{\overline{\Omega} \times [t_0, \rho_1]} = v_1$. It is easily verified that $\mathcal{V}$ is inductively ordered. Hence Zorn Lemma yields the existence of maximal elements in $\mathcal{V}$, i.e. the existence of nonextendible solutions of (2.13).

Step 3. *Behaviour of nonextendible solutions*. Let $u : \overline{\Omega} \times [t_0, \omega[\to \mathbb{R}$, with $\omega < +\infty$, be a nonextendible solution of (2.13) and assume that

$$\limsup_{t \to \omega} \|u(\cdot, t)\|_{L^\infty(\Omega)} < +\infty,$$

i.e. there is a constant $M > 0$ such that $|u(x, t)| \leqslant M$ in $\overline{\Omega} \times [t_0, \omega[$. By the Nagumo condition (N), there exist $h \in L^p(\Omega \times]t_0, \omega[)$ and $K > 0$ such that

$$|f(x,t,u,\nabla_x u)| \leqslant h(x,t) + K |\nabla_x u|^2$$

for a.e. $(x, t) \in \Omega \times]t_0, \omega[$. Proposition 2.5 implies that $u \in W_p^{2,1}(\Omega \times]t_0, \omega[)$. Hence, in particular, $u(\cdot, \omega) \in W_p^{2-2/p}(\Omega)$ and $u(\cdot, \omega) = 0$ on $\partial\Omega$. Accordingly, u can be continued to the right of ω, thus contradicting the nonextendibility of u. This allows to conclude that

$$\limsup_{t \to \omega} \|u(\cdot, t)\|_{L^\infty(\Omega)} = +\infty.$$

□

REMARK 2.9. Without the Nagumo condition (N), the conclusions of Proposition 2.9 remain true, but now

$$\limsup_{t\to\omega}\|u(\cdot,t)\|_{C^1(\overline{\Omega})}=+\infty.$$

To prove the first step in that case, we define F as in the above proof and

$$\overline{F}(x,t,s,\xi)=\max\bigl\{-m(x,t),\min\bigl\{F(x,t,s,\xi),m(x,t)\bigr\}\bigr\}$$

where $m\in L^p(\Omega\times\,]t_0,t_0+1[)$ satisfies $m(x,t)\geqslant|f(x,t,u,\xi)|+1$, for a.e. $(x,t)\in\Omega\times\,]t_0,t_0+1[$ and every $(u,\xi)\in\mathbb{R}\times\mathbb{R}^N$ with $|u_0(x)-u|\leqslant 1$ and $|\nabla_x u_0(x)-\xi|\leqslant 1$. We then consider the modified problem

$$\begin{array}{ll}\partial_t u+A(x,t,\partial_x)u=\overline{F}(x,t,u,\nabla_x u) & \text{in } \Omega\times\,]t_0,t_0+1[,\\ u=0 & \text{on } \partial\Omega\times[t_0,t_0+1],\\ u(\cdot,t_0)=u_0 & \text{in } \Omega\end{array}$$

and obtain the existence of a local solution as above. The remainder of the proof is similar.

2.4. *The periodic boundary value problem*

Let us consider the periodic problem

$$\begin{array}{ll}\partial_t u+A(x,t,\partial_x)u=f(x,t,u,\nabla_x u) & \text{in } Q_T,\\ u=0 & \text{on } \Sigma_T,\\ u(\cdot,0)=u(\cdot,T) & \text{in } \Omega,\end{array}\tag{2.36}$$

where, we recall, Q_T and Σ_T stand for $\Omega\times\,]0,T[$ and $\partial\Omega\times[0,T]$ respectively. When dealing with problem (2.36) it is convenient to introduce the following space of functions, satisfying the Dirichlet-periodic boundary conditions,

$$C_B^{1,0}\bigl(\overline{Q}_T\bigr)=\bigl\{u\in C^{1,0}\bigl(\overline{Q}_T\bigr)\mid u=0\text{ on }\Sigma_T\text{ and }u(\cdot,0)=u(\cdot,T)\text{ in }\Omega\bigr\},$$

endowed with the $C^{1,0}$-norm. We notice that, for $u\in C_B^{1,0}(\overline{Q}_T)$, we have $u\gg 0$ if and only if $u(x,t)>0$ in $\Omega\times[0,T]$ and $\partial_\nu u(x,t)<0$ on $\partial\Omega\times[0,T]$, where $\nu=\nu(x)$ is the unit outer normal to Ω at $x\in\partial\Omega$.

In this section we discuss existence and localization of solutions of the periodic problem (2.36) in the presence of a pair α, β of possibly discontinuous lower and upper solutions. We further introduce the notion of T-monotonicity and we use it to extend to the present context the Monotone Convergence Criterion known in the frame of order preserving discrete-time semidynamical systems (see, e.g., [60, Section 5]). We then give a simple application of this result to the study of a linear periodic parabolic problem. After these preliminaries we prove the main theorems of this section: existence and localization of solutions of (2.36) when $\alpha\leqslant\beta$, or when $\alpha\nleqslant\beta$. It is worthy to notice again that for problem

(2.36) the mere existence of a pair of lower and upper solutions, even satisfying $\alpha > \beta$, does not generally guarantee the existence of a solution.

Solutions and lower and upper solutions

DEFINITION 2.11. A *solution of* (2.36) is a solution u of (2.10) in $\overline{\Omega} \times \mathbb{R}$ which is T-periodic with respect to the second variable, i.e. $u(x, t + T) = u(x, t)$ in $\overline{\Omega} \times \mathbb{R}$.

DEFINITION 2.12.

- A *lower solution of* (2.36) is a function $\alpha : \overline{\Omega} \times \mathbb{R} \to \mathbb{R}$, T-periodic with respect to the second variable, which is a lower solution of (2.10) in $\overline{\Omega} \times \mathbb{R}$.
- A *regular lower solution of* (2.36) is a lower solution α of (2.36) such that $\alpha|_{\overline{\Omega}\times[0,T]}$ is a regular lower solution of (2.10) in $\overline{\Omega} \times [0, T]$.
- An *upper solution of* (2.36) is a function $\beta : \overline{\Omega} \times \mathbb{R} \to \mathbb{R}$, T-periodic with respect to the second variable, which is an upper solution of (2.10) in $\overline{\Omega} \times \mathbb{R}$.
- A *regular upper solution of* (2.36) is an upper solution β of (2.36) such that $\beta|_{\overline{\Omega}\times[0,T]}$ is a regular upper solution of (2.10) in $\overline{\Omega} \times [0, T]$.
- A lower solution of (2.36) (respectively an upper solution of (2.36)) is *proper* if it is not a solution of (2.36).
- A proper lower solution α of (2.36) is *strict* if every solution u of (2.36), with $u > \alpha$, is such that $u \gg \alpha$. Similarly, a proper upper solution β of (2.36) is *strict* if every solution u of (2.36), with $u < \beta$, is such $u \ll \beta$.

REMARK 2.10. We notice that even regular lower and upper solutions of (2.36) may be discontinuous with respect to t at the endpoints of the interval $[0, T]$.

REMARK 2.11. Sometimes we speak of solutions of (2.36) with reference to functions defined on $\overline{\Omega} \times [t_0, t_0 + T]$, and of lower and upper solutions of (2.36) with reference to functions defined on $\overline{\Omega} \times [t_0, t_0 + T[$ for some $t_0 \in \mathbb{R}$. In these cases it is understood that their T-periodic extensions to $\overline{\Omega} \times \mathbb{R}$ have to be considered.

REMARK 2.12. If α is a lower solution of (2.36) and $u \in C^{1,0}_B(\overline{Q}_T)$ is such that $u > \alpha$, then there exist an open ball $B \subseteq \Omega$ and points $t_1, t_2 \in [0, T]$, with $t_1 < t_2$, such that $u(x, t) > \alpha(x, t)$ in $B \times]t_1, t_2[$. If α is a lower solution of (2.36) and $u \in C^{1,0}_B(\overline{Q}_T)$ is such that $u \not\geq \alpha$, then there exist an open ball $B \subseteq \Omega$ and points $t_1, t_2 \in [0, T]$, with $t_1 < t_2$, such that $u(x, t) < \alpha(x, t)$ in $B \times]t_1, t_2[$. Similar conclusions hold for an upper solution β and a function $u \in C^{1,0}_B(\overline{Q}_T)$, such that $u < \beta$, or $u \not\leq \beta$.

A further Nagumo-type result

In the frame of problem (2.36) we need a Nagumo-type result that is a variant of Proposition 2.5, where the $W^{2-2/p}_p$-bound on the initial condition is replaced by a L^∞-bound on the solution itself.

PROPOSITION 2.10. *Assume* (D) *and* (A). *Let* $p > N+2$, $h \in L^p(\Omega \times]-T,T[)$, $K > 0$ *and* $R > 0$ *be given. Then there exists a constant* $C > 0$ *such that, for each* $u \in W_p^{2,1}(\Omega \times]-T,T[)$ *satisfying*

$$\begin{array}{ll} \left|\partial_t u + A(x,t,\partial_x)u\right| \leqslant h(x,t) + K|\nabla_x u|^2 & \textit{a.e. in } \Omega \times]-T,T[, \\ u = 0 & \textit{on } \partial\Omega \times [-T,T], \end{array}$$

and

$$\|u\|_{L^\infty(\Omega\times]-T,T[)} \leqslant R,$$

we have

$$\|u\|_{W_p^{2,1}(\Omega\times]0,T[)} \leqslant C.$$

PROOF. As in the proof of Proposition 2.5, it is enough to prove the following result.

CLAIM. *Let* $g \in L^\infty(\Omega \times]-T,T[)$ *and* $R > 0$ *be given. Then there is a constant* $C > 0$ *such that every* $u \in W_p^{2,1}(\Omega \times]-T,T[)$, *for which*

$$\begin{array}{ll} \partial_t u + A(x,t,\partial_x)u = g(x,t)\big(1 + |\nabla_x u|^2\big) & \textit{in } \Omega \times]-T,T[, \\ u = 0 & \textit{on } \partial\Omega \times [-T,T], \end{array} \tag{2.37}$$

and

$$\|u\|_{L^\infty(\Omega\times]-T,T[)} \leqslant R \tag{2.38}$$

hold, satisfies

$$\|u\|_{W_p^{2,1}(\Omega\times]-T,T[)} \leqslant C.$$

Fix a function u satisfying (2.37) and (2.38), and consider, for each $\lambda \in [0,1]$, the initial value problem

$$\begin{array}{ll} \partial_t u_\lambda + A(x,t,\partial_x)u_\lambda = g(x,t)\big(\lambda + |\nabla_x u_\lambda|^2\big) & \text{in } \Omega \times]-T,T[, \\ u_\lambda = 0 & \text{on } \partial\Omega \times [-T,T], \\ u_\lambda(\cdot,-T) = \lambda u(\cdot,-T) & \text{in } \Omega. \end{array} \tag{2.39}$$

As in the proof of Proposition 2.5, we see that (2.39) has at most one solution. Let $\eta = \operatorname{ess\,inf}_{\Omega\times]-T,T[} a_0 > 0$ and $M = \max\{\eta^{-1}\|g\|_{L^\infty(\Omega\times]-T,T[)}, R\}$. Since $-M$ is a lower solution and M is an upper solution of (2.39), Theorem 2.6 implies that, for every $\lambda \in [0,1]$, (2.39) has a unique solution u_λ.

Moreover, as in Proposition 2.5, we can prove that, for every $\lambda_1, \lambda_2 \in [0,1]$, the corresponding solutions $u_{\lambda_1}, u_{\lambda_2}$ of (2.39) satisfy

$$\|u_{\lambda_1} - u_{\lambda_2}\|_{L^\infty(\Omega\times]-T,T[)} \leqslant C_2|\lambda_1 - \lambda_2|. \tag{2.40}$$

Next, we set in $\Omega \times [-T, T]$,

$$v_\lambda(x,t) = \chi(t)u_\lambda(x,t),$$

where $\chi \in C^\infty(\mathbb{R}, [0,1])$ is such that

$$\chi(t) = \begin{cases} 0 & \text{if } t \leqslant -T/2, \\ 1 & \text{if } t \geqslant 0. \end{cases}$$

Each v_λ satisfies

$$\begin{array}{ll} \partial_t v_\lambda + A(x,t,\partial_x)v_\lambda = \chi(t)g(x,t)\big(\lambda + |\nabla_x u_\lambda|^2\big) + \chi'(t)u_\lambda & \text{in } \Omega \times]-T, T[, \\ v_\lambda = 0 & \text{on } \partial\Omega \times [-T, T], \\ v_\lambda(\cdot, -T) = 0 & \text{in } \Omega. \end{array} \tag{2.41}$$

For each $\lambda_1, \lambda_2 \in [0,1]$, set $w = v_{\lambda_1} - v_{\lambda_2} = \chi(u_{\lambda_1} - u_{\lambda_2})$, which satisfies

$$\begin{array}{ll} \partial_t w + A(x,t,\partial_x)w = \chi g(\lambda_1 - \lambda_2) + g\nabla_x(u_{\lambda_1} + u_{\lambda_2}) \cdot \nabla_x w + \chi'(u_{\lambda_1} - u_{\lambda_2}) & \\ \qquad\qquad\qquad \text{in } \Omega \times]-T, T[, & \\ w = 0 \qquad\qquad \text{on } \partial\Omega \times [-T, T], & \\ w(\cdot, -T) = 0 \quad \text{in } \Omega. & \end{array} \tag{2.42}$$

and, by (2.40),

$$\|w\|_{L^\infty(\Omega\times]-T,T[)} \leqslant C_2|\lambda_1 - \lambda_2|.$$

Since

$$\begin{aligned} \big|\nabla_x(u_{\lambda_1} + u_{\lambda_2}) \cdot \nabla_x w\big| &= \chi\big|\nabla_x(u_{\lambda_1} + u_{\lambda_2}) \cdot \nabla_x(u_{\lambda_1} - u_{\lambda_2})\big| \\ &\leqslant \chi|\nabla_x u_{\lambda_1}|^2 + 2\chi\big|\nabla_x(u_{\lambda_1} - u_{\lambda_2})\big|^2, \end{aligned}$$

we get

$$\begin{aligned} &\big\|\partial_t w + A(x,t,\partial_x)w\big\|_{L^p(\Omega\times]-T,T[)} \\ &\quad \leqslant C_4\big(\big\|\chi|\nabla_x u_{\lambda_1}|^2\big\|_{L^p(\Omega\times]-T,T[)} + \big\|\chi|\nabla_x(u_{\lambda_1} - u_{\lambda_2})|^2\big\|_{L^p(\Omega\times]-T,T[)}\big) + C_3. \end{aligned} \tag{2.43}$$

As in the proof of Proposition 2.5, we also have, by (2.40),

$$\begin{aligned}&\big\|\chi\,|\nabla_x(u_{\lambda_1}-u_{\lambda_2})|^2\big\|_{L^p(\Omega\times]-T,T[)}\\&\quad\leqslant C_5\|u_{\lambda_1}-u_{\lambda_2}\|_{L^\infty(\Omega\times]-T,T[)}\big\|\chi(u_{\lambda_1}-u_{\lambda_2})\big\|_{W_p^{2,1}(\Omega\times]-T,T[)}\\&\quad\leqslant C_2C_5|\lambda_1-\lambda_2|\|w\|_{W_p^{2,1}(\Omega\times]-T,T[)},\end{aligned}\tag{2.44}$$

and in particular,

$$\big\|\chi|\nabla_x u_{\lambda_1}|^2\big\|_{L^p(\Omega\times]-T,T[)}\leqslant C_2C_5\lambda_1\|v_{\lambda_1}\|_{W_p^{2,1}(\Omega\times]-T,T[)}.\tag{2.45}$$

Using (2.43), (2.44), (2.45) and Proposition 2.4, we get

$$\begin{aligned}&\|w\|_{W_p^{2,1}(\Omega\times]-T,T[)}\\&\quad\leqslant C_6+C_7\|v_{\lambda_1}\|_{W_p^{2,1}(\Omega\times]-T,T[)}+C_8|\lambda_1-\lambda_2|\|w\|_{W_p^{2,1}(\Omega\times]-T,T[)}.\end{aligned}$$

This also yields

$$\|w\|_{W_p^{2,1}(\Omega\times]-T,T[)}\leqslant 2C_6+2C_7\|v_{\lambda_1}\|_{W_p^{2,1}(\Omega\times]-T,T[)}$$

provided that $|\lambda_1-\lambda_2|\leqslant\varepsilon=(2C_8)^{-1}$. Hence, in particular, we have, for each $\lambda\in[0,\varepsilon]$,

$$\|v_\lambda\|_{W_p^{2,1}(\Omega\times]-T,T[)}\leqslant 2C_6.$$

Finally, iterating this process a finite number of times, we conclude that there is a constant C_9 such that

$$\|v_1\|_{W_p^{2,1}(\Omega\times]-T,T[)}\leqslant C_9$$

and hence

$$\|u\|_{W_p^{2,1}(\Omega\times]0,T[)}\leqslant C_9.$$ □

T-monotonicity and asymptotic behaviour of bounded solutions

DEFINITION 2.13. A function $u:\overline{\Omega}\times I\to\mathbb{R}$, where $I\subseteq\mathbb{R}$ is an interval, is said *T-increasing* (respectively *T-decreasing*) if $u(x,t)\leqslant u(x,t+T)$ (respectively $u(x,t+T)\geqslant u(x,t)$) for every $x\in\overline{\Omega}$ and each $t\in I$ such that $t+T\in I$. A function is said *T-monotone* if it is either T-increasing or T-decreasing.

REMARK 2.13. Let u be a solution of (2.10) on $\overline{\Omega}\times[t_0,+\infty[$. If u is T-increasing then the sequence $(\alpha_n)_n$, defined by setting, for each $n\geqslant t_0/T$, $\alpha_n(x,t)=u(x,t+nT)$ in $\overline{\Omega}\times[0,T[$, gives rise to an increasing sequence of regular lower solutions of (2.36). Similarly, any T-decreasing solution of (2.10) in $\overline{\Omega}\times[t_0,+\infty[$, gives rise to a decreasing sequence $(\beta_n)_n$ of regular upper solutions of (2.36).

The T-monotonicity property is a basic tool to prove convergence of a bounded solution u defined on $\overline{\Omega} \times [t_0, +\infty[$ to a T-periodic solution v. We start with a simple preliminary result where the T-monotonicity of u is replaced by a weaker request: the monotonicity of the sequence $(u(\cdot, nT))_n$, with $n \geqslant t_0/T$. However, in this case only the existence of a T-periodic solution v lying in the ω-limit set of u is guaranteed, not the convergence of u to v.

LEMMA 2.11. *Assume* (D), (A), (C) *and* (N). *Let u be a solution of* (2.10) *in $\overline{\Omega} \times [t_0, +\infty[$, which is bounded in $\overline{\Omega} \times [t_0, +\infty[$ and such that either $u(\cdot, nT) \leqslant u(\cdot, (n+1)T)$ in $\overline{\Omega}$ for every $n \geqslant t_0/T$, or $u(\cdot, nT) \geqslant u(\cdot, (n+1)T)$ in $\overline{\Omega}$ for every $n \geqslant t_0/T$. Then problem* (2.36) *has at least one solution.*

PROOF. Assume that $u(\cdot, nT) \leqslant u(\cdot, (n+1)T)$ in $\overline{\Omega}$ for every $n \geqslant t_0/T$. Define a sequence $(u_n)_n$ by setting $u_n(x,t) = u(x, t + nT)$ in $\overline{Q}_T$. By Proposition 2.10, we know that the sequence $(u_n)_n$ is bounded in $W^{2,1}_p(Q_T)$. Hence there exists a subsequence $(u_{n_k})_k$ which converges to a solution v of (2.10) in $\overline{Q}_T$ weakly in $W^{2,1}_p(Q_T)$ and strongly in $C^{1,0}(\overline{Q}_T)$. Moreover, as the sequences $(u_n(\cdot, 0))_n$ and $(u_n(\cdot, T))_n$ satisfy $u_n(\cdot, 0) \leqslant u_n(\cdot, T) = u_{n+1}(\cdot, 0)$, we have $u_{n_k}(\cdot, 0) \leqslant u_{n_k}(\cdot, T) \leqslant u_{n_{k+1}}(\cdot, 0)$ and, passing to the limit, $v(\cdot, 0) \leqslant v(\cdot, T) \leqslant v(\cdot, 0)$. Therefore v is a solution of (2.36). □

PROPOSITION 2.12. *Assume* (D), (A), (C) *and* (N). *Let u be a solution of* (2.10) *in $\overline{\Omega} \times [t_0, +\infty[$, which is bounded in $\bar{\Omega} \times [t_0, +\infty[$ and T-monotone. Then there exists a solution v of* (2.36) *such that*

$$\lim_{t \to +\infty} \left\| u(\cdot, t) - v(\cdot, t) \right\|_{C^1(\overline{\Omega})} = 0.$$

PROOF. Assume that u is T-increasing. Define a sequence $(u_n)_n$ by setting, for every $n \geqslant t_0/T$, $u_n(x,t) = u(x, t + nT)$ in $\overline{Q}_T$. From the proof of Lemma 2.11, we know that a subsequence of $(u_n)_n$ converges to a solution v of (2.36) weakly in $W^{2,1}_p(Q_T)$ and strongly in $C^{1,0}(\overline{Q}_T)$. The monotonicity of $(u_n)_n$ then implies that the whole sequence $(u_n)_n$ converges to v. It remains to prove that

$$\lim_{t \to +\infty} \left\| u(\cdot, t) - v(\cdot, t) \right\|_{C^1(\overline{\Omega})} = 0.$$

Indeed, since $(u_n)_n$ converges in $C^{1,0}(\overline{Q}_T)$ to v, given $\varepsilon > 0$ there is $\bar{n}$ such that, for any $n \geqslant \bar{n}$,

$$\left\| u_n(\cdot, t) - v(\cdot, t) \right\|_{C^1(\bar{\Omega})} < \varepsilon, \quad \text{for all } t \in [0, T].$$

Hence, if we take $t \geqslant \bar{n}T$, with $t \in [nT, (n+1)T[$ for some $n \geqslant \bar{n}$, we obtain

$$\left\| u(\cdot, t) - v(\cdot, t) \right\|_{C^1(\overline{\Omega})} = \left\| u_n(\cdot, t - nT) - v(\cdot, t - nT) \right\|_{C^1(\overline{\Omega})} < \varepsilon,$$

by the periodicity of v. □

A Monotone Convergence Criterion

We now prove that any bounded solution of (2.10) emanating from and lying above a lower solution of (2.36), or respectively emanating from and lying below an upper solution of (2.36), is T-monotone and hence converges to a T-periodic solution. We point out that, in space dimension $N \geqslant 2$, convergence to a T-periodic solution is not the behaviour of all bounded solutions of (2.10), due to the possible occurrence of (linearly stable) subharmonic solutions (see, e.g., [141,35] and [123, Section 3]). In our frame additional difficulties come from the lack of regularity of f, so that even generic convergence results, possibly to subharmonic solutions of (2.10), are not available (see [123, Section 3]). For a discussion of the regular case in space dimension $N = 1$ we refer to [56].

PROPOSITION 2.13. *Assume* (D), (A), (C) *and* (N).

(i) *Let* α *be a lower solution of* (2.36) *such that, for some* t_0, $\alpha(\cdot, t_0) \in W_p^{2-2/p}(\Omega)$ *and* $\alpha(\cdot, t_0) = 0$ *on* $\partial\Omega$. *Then there exist* $\omega \in\,]t_0, +\infty]$ *and a* T*-increasing solution* $\widetilde{\alpha} : \overline{\Omega} \times [t_0, \omega[\, \to \mathbb{R}$ *of* (2.13), *with* $u_0 = \alpha(\cdot, t_0)$, *satisfying* $\widetilde{\alpha} \geqslant \alpha$ *in* $\overline{\Omega} \times [t_0, \omega[$. *Further, every solution* $u : \overline{\Omega} \times [t_0, \sigma[\, \to \mathbb{R}$ *of* (2.10), *with* $u \geqslant \alpha$, *is such that* $\sigma \leqslant \omega$ *and* $u \geqslant \widetilde{\alpha}$ *in* $\overline{\Omega} \times [t_0, \sigma[$. *Finally, we have that either every nonextendible solution* $u : \overline{\Omega} \times [t_0, \sigma[\, \to \mathbb{R}$ *of* (2.10), *with* $u \geqslant \alpha$, *is such that*

$$\limsup_{t \to \sigma} \Bigl(\max_{\overline{\Omega}} u(\cdot, t) \Bigr) = +\infty$$

and (2.36) *has no solution in* $[\alpha, +\infty[$, *or there exists the minimum solution* v *in* $[\alpha, +\infty[$ *of* (2.36); *in the latter case* $\omega = +\infty$, $v \geqslant \widetilde{\alpha}$ *and*

$$\lim_{t \to +\infty} \bigl\| \widetilde{\alpha}(\cdot, t) - v(\cdot, t) \bigr\|_{C^1(\overline{\Omega})} = 0.$$

(ii) *Let* β *be an upper solution of* (2.36) *such that, for some* t_0, $\beta(\cdot, t_0) \in W_p^{2-2/p}(\Omega)$ *and* $\beta(\cdot, t_0) = 0$ *on* $\partial\Omega$. *Then there exist* $\omega \in\,]t_0, +\infty]$ *and a* T*-decreasing solution* $\widetilde{\beta} : \overline{\Omega} \times [t_0, \omega[\, \to \mathbb{R}$ *of* (2.13), *with* $u_0 = \beta(\cdot, t_0)$, *satisfying* $\widetilde{\beta} \leqslant \beta$ *in* $\overline{\Omega} \times [t_0, \omega[$. *Further, every solution* $u : \overline{\Omega} \times [t_0, \sigma[\, \to \mathbb{R}$ *of* (2.10), *with* $u \leqslant \beta$, *is such that* $\sigma \leqslant \omega$ *and* $u \leqslant \widetilde{\beta}$ *in* $\overline{\Omega} \times [t_0, \sigma[$. *Finally, we have that either every nonextendible solution* $u : \overline{\Omega} \times [t_0, \sigma[\, \to \mathbb{R}$ *of* (2.10), *with* $u \leqslant \beta$, *is such that*

$$\liminf_{t \to \sigma} \Bigl(\min_{\overline{\Omega}} u(\cdot, t) \Bigr) = -\infty$$

and (2.36) *has no solution in* $]-\infty, \beta]$, *or there exists the maximum solution* w *in* $]-\infty, \beta]$ *of* (2.36); *in the latter case* $\omega = +\infty$, $w \leqslant \widetilde{\beta}$ *and*

$$\lim_{t \to +\infty} \bigl\| \widetilde{\beta}(\cdot, t) - w(\cdot, t) \bigr\|_{C^1(\overline{\Omega})} = 0.$$

PROOF. We only prove statement (i), as the proof of (ii) is similar.

The existence of $\widetilde{\alpha}$ follows from Lemma 2.8. Namely, there exist $\omega \in\,]t_0, +\infty]$ and a solution $\widetilde{\alpha} : \overline{\Omega} \times [t_0, \omega[\, \to \mathbb{R}$ of (2.13), with $u_0 = \alpha(\cdot, t_0)$, satisfying $\widetilde{\alpha} \geqslant \alpha$ in $\overline{\Omega} \times [t_0, \omega[$;

further, every solution $u:\overline{\Omega} \times [t_0, \sigma] \to \mathbb{R}$ of (2.10), with $u \geqslant \alpha$, is such that $\sigma \leqslant \omega$ and $u \geqslant \widetilde{\alpha}$ in $\overline{\Omega} \times [t_0, \sigma]$.

Let us prove that $\widetilde{\alpha}$ is T-increasing. We can assume that $\omega > t_0 + T$ as otherwise there is nothing to prove. Notice first that $\widetilde{\alpha}(\cdot, t_0 + T) \geqslant \alpha(\cdot, t_0 + T) = \alpha(\cdot, t_0) = \widetilde{\alpha}(\cdot, t_0)$ in $\overline{\Omega}$. Assume, by contradiction, there exist $x_1 \in \Omega$ and $t_1 \geqslant t_0$ such that

$$\widetilde{\alpha}(x_1, t_1 + T) < \widetilde{\alpha}(x_1, t_1).$$

If $\omega < +\infty$, we set $\beta(x, t) = \min\{\widetilde{\alpha}(x, t + T), \widetilde{\alpha}(x, t)\}$ in $\overline{\Omega} \times [t_0, \omega - T[$. Then β is an upper solution of (2.13), with $u_0 = \alpha(\cdot, t_0)$, in $\overline{\Omega} \times [t_0, \omega - T[$, satisfying $\beta \geqslant \alpha$. Hence, by Theorem 2.6, there exists a solution w of (2.13), with $u_0 = \alpha(\cdot, t_0)$, in $\overline{\Omega} \times [t_0, \omega - T[$, satisfying $\alpha \leqslant w \leqslant \beta$. If $\omega = +\infty$, we set $\beta(x, t) = \min\{\widetilde{\alpha}(x, t + T), \widetilde{\alpha}(x, t)\}$ in $\overline{\Omega} \times [t_0, +\infty[$. Then β is an upper solution of (2.13), with $u_0 = \alpha(\cdot, t_0)$, in $\overline{\Omega} \times [t_0, +\infty[$, satisfying $\beta \geqslant \alpha$. Hence, by Corollary 2.7, there exists a solution w of (2.13), with $u_0 = \alpha(\cdot, t_0)$, in $\overline{\Omega} \times [t_0, +\infty[$, satisfying $\alpha \leqslant w \leqslant \beta$. In both cases, since $\beta < \widetilde{\alpha}$, we get $w < \widetilde{\alpha}$, thus contradicting the definition of $\widetilde{\alpha}$.

By Proposition 2.9, either every nonextendible solution $u:\overline{\Omega} \times [0, \sigma[\to \mathbb{R}$ of (2.10), with $u \geqslant \alpha$, is such that

$$\limsup_{t \to \sigma} \Big(\max_{\overline{\Omega}} u(\cdot, t) \Big) = +\infty$$

and in particular (2.36) has no solution in $[\alpha, +\infty[$, or $\omega = +\infty$ and $\widetilde{\alpha}$ is bounded in $\overline{\Omega} \times [t_0, +\infty[$. In the latter case, as $\tilde{\alpha}$ is T-increasing, by Proposition 2.12, there exists a solution $v \geqslant \widetilde{\alpha}$ of (2.36) such that

$$\lim_{t \to +\infty} \left\| \widetilde{\alpha}(\cdot, t) - v(\cdot, t) \right\|_{C^1(\overline{\Omega})} = 0.$$

Let us prove that v is the minimum solution of (2.36) in $[\alpha, +\infty[$. Otherwise, if $\bar{v}$ were a solution of (2.36) with $\bar{v} \geqslant \alpha$ and $\bar{v} \not\geqslant v$, then $\min\{v, \bar{v}\}$ should be an upper solution of (2.13), with $u_0 = \alpha(\cdot, t_0)$, in $\overline{\Omega} \times [t_0, +\infty[$, such that $\min\{v, \bar{v}\} \geqslant \alpha$ and $\min\{v, \bar{v}\} \not\geqslant \widetilde{\alpha}$. By Corollary 2.7, there should exist a solution z of (2.13), with $u_0 = \alpha(\cdot, t_0)$, in $\overline{\Omega} \times [t_0, +\infty[$, such that $\alpha \leqslant z \leqslant \min\{v, \bar{v}\}$, thus contradicting the definition of $\widetilde{\alpha}$. □

A linear periodic problem

As a simple application of Proposition 2.13, we get a result that concerns existence, uniqueness and regularity of the solution of the linear periodic problem

$$\begin{aligned} &\partial_t u + A(x, t, \partial_x) u + \sigma u = h(x, t) && \text{in } Q_T, \\ &u = 0 && \text{on } \Sigma_T, \\ &u(\cdot, 0) = u(\cdot, T) && \text{in } \Omega, \end{aligned} \tag{2.46}$$

where $\sigma \geqslant 0$ is fixed and $h \in L^p(Q_T)$ for some $p > N + 2$. Although proofs can be found in [84, Lemma 4.1 and Corollary 5.6], we use here an alternative approach which is more in the spirit of this work and will yield, as a byproduct, the global asymptotic stability of the solution (see Proposition 2.35). We associate with problem (2.46) the linear operator

$$L : W^{2,1}_{p,B}(Q_T) \to L^p(Q_T), \tag{2.47}$$

defined by

$$Lu = \partial_t u - \sum_{i,j=1}^{N} \partial_{x_i}\big(a_{ij}(x,t)\partial_{x_j} u\big) + \sum_{i=1}^{N} a_i(x,t)\partial_{x_i} u + a_0(x,t)u, \tag{2.48}$$

where

$$\begin{aligned} W^{2,1}_{p,B}(Q_T) &= W^{2,1}_p(Q_T) \cap C^{1,0}_B\big(\overline{Q}_T\big) \\ &= \big\{u \in W^{2,1}_p(Q_T) \mid u = 0 \text{ on } \Sigma_T \text{ and } u(\cdot,0) = u(\cdot,T) \text{ in } \Omega\big\}. \end{aligned}$$

Notice that $W^{2,1}_{p,B}(Q_T)$ is a Banach subspace of $W^{2,1}_p(Q_T)$ and L is a bounded operator.

PROPOSITION 2.14. *Assume* (D) *and* (A). *Let* $p > N + 2$ *be fixed. Then, for every* $\sigma \geqslant 0$ *and for any given* $h \in L^p(Q_T)$, *problem* (2.46) *has a unique solution* $u \in W^{2,1}_p(Q_T)$. *Moreover, there exists a constant* C, *independent of* h, *such that*

$$\|u\|_{W^{2,1}_p(Q_T)} \leqslant C\|h\|_{L^p(Q_T)}.$$

PROOF. The proof consists of four steps.

Step 1. *Problem* (2.46) *has at most one solution.* The conclusion immediately follows showing that any function $u \in W^{2,1}_p(Q_T)$, satisfying

$$\begin{aligned} &\partial_t u + A(x,t,\partial_x)u + \sigma u \geqslant 0 && \text{in } Q_T, \\ &u \geqslant 0 && \text{on } \Sigma_T, \\ &u(\cdot,0) = u(\cdot,T) && \text{in } \Omega, \end{aligned}$$

is such that $u \geqslant 0$. Indeed, assume by contradiction that $\min_{\overline{Q}_T} u < 0$. Since $u(\cdot,0) = u(\cdot,T)$ in Ω and $u \geqslant 0$ on Σ_T, there exists $(x_0,t_0) \in \Omega \times\,]0,T]$ such that $u(x_0,t_0) = \min_{\overline{Q}_T} u$. Then Proposition 2.2 implies that u is constant in $\bar{\Omega} \times [0,t_0]$. This yields a contradiction, as then

$$\partial_t u + A(x,t,\partial_x)u + \sigma u = (a_0 + \sigma)u < 0, \quad \text{a.e. in } \Omega \times [0,t_0].$$

Step 2. *Problem* (2.46) *has a solution for any given* $h \geqslant 0$. The function $\alpha = 0$ is obviously a lower solution of (2.46) with $\alpha(\cdot,0) \in W^{2-2/p}_p(\Omega)$ and $\alpha(\cdot,0) = 0$ on $\partial\Omega$. Let us build an upper solution of (2.46). Let z be the unique solution of

$$\begin{aligned} &\partial_t u + A(x,t,\partial_x)u + \sigma u = h(x,t) && \text{in } Q_T, \\ &u = 0 && \text{on } \Sigma_T, \\ &u(\cdot,0) = 0 && \text{in } \Omega. \end{aligned}$$

Define a function $\beta \in W_p^{2,1}(Q_T)$, by setting

$$\beta(x,t) = z(x,t) + at + b \quad \text{in } \overline{\Omega} \times [0, T[,$$

where $a \leqslant 0$ and $b \geqslant 0$ are constants chosen in such a way that

$$aT + \left\| z(\cdot, T) \right\|_{L^\infty(\Omega)} \leqslant 0 \quad \text{and} \quad a + \Bigl(\sigma + \operatorname*{ess\,inf}_{Q_T} a_0\Bigr)(aT + b) \geqslant 0.$$

Accordingly, β satisfies

$$\begin{aligned} &\partial_t \beta + A(x,t,\partial_x)\beta + \sigma\beta \geqslant h(x,t) && \text{in } Q_T, \\ &\beta \geqslant 0 && \text{on } \Sigma_T, \\ &\beta(\cdot, 0) \geqslant \lim_{t \to T^-} \beta(\cdot, t) && \text{in } \Omega \end{aligned}$$

and hence β is an upper solution of (2.46). We apply Corollary 2.7 and Proposition 2.13 to deduce the existence of a T-increasing solution $\widetilde{\alpha} : \overline{\Omega} \times [0, +\infty[\to \mathbb{R}$ of

$$\begin{aligned} &\partial_t u + A(x,t,\partial_x)u + \sigma u = h(x,t) && \text{in } \Omega \times]0, +\infty[, \\ &u = 0 && \text{on } \partial\Omega \times [0, +\infty[, \\ &u(\cdot, 0) = 0 && \text{in } \Omega \end{aligned}$$

and of a solution v of (2.46) in $[0, \beta]$, which by Step 1 is the unique solution of (2.46). Further, we have

$$\lim_{t \to +\infty} \left\| \widetilde{\alpha}(\cdot, t) - v(\cdot, t) \right\|_{C^1(\bar{\Omega})} = 0.$$

Step 3. *Problem* (2.46) *has a solution for any given h*. Let us define the functions $h^+ = \max\{h, 0\}$, $h^- = h^+ - h$ and consider the periodic problems

$$\begin{aligned} &\partial_t u + A(x,t,\partial_x)u + \sigma u = h^+(x,t) && \text{in } Q_T, \\ &u = 0 && \text{on } \Sigma_T, \\ &u(\cdot, 0) = u(\cdot, T) && \text{in } \Omega \end{aligned}$$

and

$$\begin{aligned} &\partial_t u + A(x,t,\partial_x)u + \sigma u = h^-(x,t) && \text{in } Q_T, \\ &u = 0 && \text{on } \Sigma_T, \\ &u(\cdot, 0) = u(\cdot, T) && \text{in } \Omega. \end{aligned}$$

Denote by u_+ and u_- the corresponding solutions, constructed in Step 2. By linearity, we conclude that $u = u_+ - u_-$ is the solution of (2.46).

Step 4. *Continuous dependence.* Since the linear operator $L + \sigma I : W^{2,1}_{p,B}(Q_T) \to L^p(Q_T)$ is continuous, one-to-one and onto and its domain $W^{2,1}_{p,B}(Q_T)$ is a Banach space, the Open Mapping Theorem yields the estimate

$$\|u\|_{W^{2,1}_p(Q_T)} \leqslant C\|h\|_{L^p(Q_T)}. \qquad \square$$

Existence in case $\alpha \leqslant \beta$

The following result yields the existence of extremal solutions of (2.36) in the presence of lower and upper solutions α, β satisfying the condition $\alpha \leqslant \beta$. This extends to strong solutions previous results obtained, e.g., in [73,8,6,33,58] for classical solutions. For later use we also evaluate the degree of the fixed point operator associated with (2.36), when the lower and the upper solutions are strict. To this end we denote by $S : C^{1,0}_B(\overline{Q}_T) \to C^{1,0}_B(\overline{Q}_T)$ the operator, which according to Proposition 2.14 sends any function $u \in C^{1,0}_B(\overline{Q}_T)$ onto the unique solution $v \in W^{2,1}_p(Q_T)$ of

$$\begin{array}{ll} \partial_t v + A(x,t,\partial_x)v = f(x,t,u,\nabla_x u) & \text{in } Q_T, \\ v = 0 & \text{on } \Sigma_T, \\ v(\cdot,0) = v(\cdot,T) & \text{in } \Omega. \end{array} \tag{2.49}$$

THEOREM 2.15. *Assume* (D), (A), (C) *and* (N). *Suppose that α is a lower solution and β is an upper solution of* (2.36) *satisfying*

$$\alpha \leqslant \beta.$$

Then there exist the minimum solution v and the maximum solution w of (2.36) *in* $[\alpha, \beta]$. *Further, if α and β are strict, then the operator S defined by* (2.49) *has no fixed point on the boundary of*

$$\mathcal{U} = \left\{u \in C^{1,0}_B\left(\overline{Q}_T\right) \mid \alpha \ll u \ll \beta\right\},$$

the set of fixed points of S in $\mathcal{U}$ is bounded in $C^{1,0}_B(\overline{Q}_T)$ and

$$\deg\bigl(I - S, \mathcal{U} \cap B(0,R)\bigr) = 1,$$

where I is the identity operator in $C^{1,0}_B(\overline{Q}_T)$ and $B(0,R)$ is the open ball of center 0 *and radius R in $C^{1,0}_B(\overline{Q}_T)$, with R so large that all fixed points of S in $\mathcal{U}$ belong to $B(0,R)$.*

PROOF. The proof is divided into three parts.

Part 1. *Existence of a solution u of* (2.36) *with $\alpha \leqslant u \leqslant \beta$.* According to Remark 2.4, we can assume that the sequences $(\sigma_h)_{0\leqslant h\leqslant k}$ and $(\rho_h)_{0\leqslant h\leqslant l}$ coincide. We also notice that, by our definition of lower and upper solutions of (2.36) and the condition $\alpha \leqslant \beta$, there exists $M > 0$ such that $-M \leqslant \alpha(x,t) \leqslant \beta(x,t) \leqslant M$ in $\overline{Q}_T$. Hence, by condition (N) and

Proposition 2.10, there exists $R > 0$ such that, for every function f satisfying (2.11) and every solution u of (2.36) with $\alpha \leqslant u \leqslant \beta$, we have

$$\|u\|_{C^{1,0}(\overline{Q}_T)} < R. \tag{2.50}$$

Exactly as in the first part of the proof of Theorem 2.6, we define a function $F : Q_T \times \mathbb{R} \times \mathbb{R}^N \to \mathbb{R}$ with $\Omega \times]t_0, t_1[$ replaced by $\Omega \times]0, T[$. Then we consider the modified problem

$$\begin{array}{ll} \partial_t u + A(x,t,\partial_x)u = F(x,t,u,\nabla_x u) & \text{in } Q_T, \\ u = 0 & \text{on } \Sigma_T, \\ u(\cdot,0) = u(\cdot,T) & \text{in } \Omega. \end{array} \tag{2.51}$$

Step 1. *Every solution u of* (2.51) *satisfies $\alpha \leqslant u \leqslant \beta$.* This can be proved as in the corresponding step of the proof of Theorem 2.6. We just observe that, if u is a solution of (2.51) such that $\inf_{Q_T}(u - \alpha) < 0$, then by our definition of a lower solution of (2.51) either there exists $h \in \{0, \dots, k-1\}$ such that $\inf_{\Omega\times]\sigma_h,\sigma_{h+1}[}(u - \alpha) < 0$ and, for all $x \in \Omega$, $\lim_{t\to\sigma_h^+}(u - \alpha)(x,t) > \inf_{\Omega\times]\sigma_h,\sigma_{h+1}[}(u - \alpha)$, or $\inf_{\Omega\times]\sigma_h,\sigma_{h+1}[}(u - \alpha) = \inf_{\Omega\times]\sigma_{h-1},\sigma_h[}(u - \alpha)$ for every $h \in \{1, \dots, k-1\}$. In any case we can find $h \in \{0, \dots, k-1\}$ and $i \in \{1, \dots, m_h\}$ such that, setting $v = u - \alpha_i^{(h)} \in W_p^{2,1}(\Omega \times]\sigma_h, \sigma_{h+1}[)$, we have $v(x,t) \geqslant 0$ on $\partial\Omega \times [\sigma_h, \sigma_{h+1}]$ and there exists $(\bar{x}, \bar{t}) \in \Omega \times]\sigma_h, \sigma_{h+1}]$ such that $\min_{\overline{\Omega}\times[\sigma_h,\sigma_{h+1}]} v = v(\bar{x}, \bar{t}) < 0$.

Step 2. *Every solution u of* (2.51) is *a solution of* (2.36). Again this can be proved as in the corresponding step of the proof of Theorem 2.6.

Step 3. *Problem* (2.51) *has at least one solution.* Let us consider the solution operator $\overline{S} : C_B^{1,0}(\overline{Q}_T) \to C_B^{1,0}(\overline{Q}_T)$ associated with (2.51), which sends any function $u \in C_B^{1,0}(\overline{Q}_T)$ onto the unique solution $v \in W_p^{2,1}(Q_T)$ of

$$\begin{array}{ll} \partial_t v + A(x,t,\partial_x)v = F(x,t,u,\nabla_x u) & \text{in } Q_T, \\ v = 0 & \text{on } \Sigma_T, \\ v(\cdot,0) = v(\cdot,T) & \text{in } \Omega. \end{array}$$

The operator $\overline{S}$ is continuous, has a relatively compact range and its fixed points are the solutions of (2.51). Hence there exists a constant $\overline{R} > 0$, that we can suppose larger than R, such that

$$\|\overline{S}u\|_{C^{1,0}(\overline{Q}_T)} < \overline{R},$$

for every $u \in C_B^{1,0}(\overline{Q}_T)$, and

$$\deg\bigl(I - \overline{S}, B\bigl(0, \overline{R}\bigr)\bigr) = 1, \tag{2.52}$$

where I is the identity operator in $C_B^{1,0}(\overline{Q}_T)$ and $B(0, \overline{R})$ is the open ball of center 0 and radius $\overline{R}$ in $C_B^{1,0}(\overline{Q}_T)$. Therefore $\overline{S}$ has a fixed point. By the conclusions of Steps 1 and 2, we get the existence of a solution u of (2.13) satisfying $\alpha \leqslant u \leqslant \beta$.

Part 2. *Extremal solutions.* Again this can be proved as in the corresponding part of the proof of Theorem 2.6.

Part 3. *Degree computation.* Now, let us assume that α and β are strict lower and upper solutions respectively. Since there exists a solution u of (2.36), which satisfies $\alpha \leqslant u \leqslant \beta$, and every such a solution satisfies $\alpha \ll u \ll \beta$, it follows that $\alpha \ll \beta$. Hence $\mathcal{U}$ is a non-empty open set in $C_B^{1,0}(\overline{Q}_T)$ and there is no fixed point either of S or of $\overline{S}$ on its boundary $\partial\mathcal{U}$. Moreover, by (2.50), the sets of fixed points of S and $\overline{S}$ coincide on $\mathcal{U} \cap B(0, R)$ and we have

$$\deg\bigl(I - S, \mathcal{U} \cap B(0, R)\bigr) = \deg\bigl(I - \overline{S}, \mathcal{U} \cap B(0, R)\bigr).$$

Furthermore, by the excision property of the degree, we get from (2.50) and (2.52)

$$\deg\bigl(I - \overline{S}, B(0, R)\bigr) = 1.$$

Finally, since all fixed points of $\overline{S}$ are in $\mathcal{U} \cap B(0, R)$, we conclude

$$\begin{aligned}\deg\bigl(I - S, \mathcal{U} \cap B(0, R)\bigr) &= \deg\bigl(I - \overline{S}, \mathcal{U} \cap B(0, R)\bigr)\\ &= \deg\bigl(I - \overline{S}, B(0, R)\bigr) = 1.\end{aligned}$$

□

REMARK 2.14. We assumed condition (N) in Theorem 2.15 in order to unify the presentation with the rest of this work. However, here it would be enough to assume the existence of $K > 0$ and $h \in L^p(Q_T)$, with $p > N + 2$, such that, for a.e. $(x, t) \in Q_T$, every $s \in [\alpha(x, t), \beta(x, t)]$ and every $\xi \in \mathbb{R}^N$,

$$\bigl|f(x, t, s, \xi)\bigr| \leqslant h(x, t) + K|\xi|^2.$$

Existence in case $\alpha \nleqslant \beta$

We now discuss the existence of solutions of (2.36) in the presence of lower and upper solutions α, β such that $\alpha \nleqslant \beta$. As we already pointed out, in the frame of problem (2.36) the sole existence of a pair of lower and upper solutions, even satisfying $\alpha > \beta$, does not generally guarantee the existence of a solution. At the light of the example presented in the introduction of this part (cf. (2.8)), we prove a result which is related to the classical Amann–Kolesov Three Solutions Theorem [73,5,7] and requires the existence of a further pair of lower and upper solutions α_1, β_1 such that $\alpha_1 \leqslant \beta_1$ and $\alpha, \beta \in [\alpha_1, \beta_1]$. Theorem 2.17 yields the existence of maximal and minimal solutions of (2.36) in $[\alpha_1, \beta_1]$ belonging to the $C^{1,0}$-closure of the set

$$\mathcal{V} = \bigl\{u \in C_B^{1,0}\bigl(\overline{Q}_T\bigr) \mid u \ngeqslant \alpha \text{ and } u \nleqslant \beta\bigr\}. \tag{2.53}$$

The proof of Theorem 2.17 makes use of the following statement concerning the existence of extremal solutions of (2.36).

LEMMA 2.16. *Assume* (D), (A), (C) *and* (N). *Let* $\mathcal{S}$ *be a nonempty set of solutions of* (2.36). *Suppose that* $\mathcal{S}$ *is uniformly bounded from above, i.e. there is a constant* M *such that* $\max_{Q_T} u \leqslant M$ *for all* $u \in \mathcal{S}$. *Then there exists a maximal solution* w *of* (2.36) *in the* $C^{1,0}$*-closure* $\bar{\mathcal{S}}$ *of* $\mathcal{S}$. *Similarly, if* $\mathcal{S}$ *is uniformly bounded from below, then there exists a minimal solution* v *of* (2.36) *in the* $C^{1,0}$*-closure* $\bar{\mathcal{S}}$ *of* $\mathcal{S}$.

PROOF. We can repeat step by step the proof of Lemma 1.15, with just the following specifications. The set $\mathcal{D} = \{(x_m, t_m) \mid m \in \mathbb{N}\}$ is a countable dense subset of Q_T. The sequence $(u_n)_n$, constructed as in Lemma 1.15, is bounded in $L^\infty(Q_T)$ and, by Proposition 2.10, it is bounded in $W_p^{2,1}(Q_T)$. Hence there is a subsequence converging weakly in $W_p^{2,1}(Q_T)$ to some function $\hat{u} \in W_p^{2,1}(Q_T)$, which is a solution of (2.36). The conclusion then follows as in Lemma 1.15. □

THEOREM 2.17. *Assume* (D), (A), (C) *and* (N). *Suppose that* α *is a lower solution and* β *is an upper solution of* (2.36) *satisfying*

$$\alpha \not\leqslant \beta.$$

Moreover, assume that there exist a lower solution α_1 *and an upper solution* β_1 *of* (2.36) *such that* $\alpha_1 \leqslant \beta_1$ *and* $\alpha, \beta \in [\alpha_1, \beta_1]$. *Then problem* (2.36) *has at least one minimal solution* v *and at least one maximal solution* w *in* $\overline{\mathcal{V}} \cap [\alpha_1, \beta_1]$ *with* $\mathcal{V}$ *defined by* (2.53). *Further, if* α, β *and* α_1, β_1 *are strict, then the solution operator* S *corresponding to* (2.49) *has no fixed point on the boundary of* $\mathcal{V} \cap [\alpha_1, \beta_1]$, *the set of fixed points of* S *in* $\mathcal{V} \cap [\alpha_1, \beta_1]$ *is bounded in* $C_B^{1,0}(\overline{Q}_T)$ *and*

$$\deg\bigl(I - S, \mathcal{V} \cap \mathcal{U} \cap B(0, R)\bigr) = -1,$$

where I *is the identity operator in* $C_B^{1,0}(\overline{Q}_T)$, $\mathcal{U} = \{u \in C_B^{1,0}(\overline{Q}_T) \mid \alpha_1 \ll u \ll \beta_1\}$ *and* $B(0, R)$ *is the open ball of center* 0 *and radius* R *in* $C_B^{1,0}(\overline{Q}_T)$, *with* R *so large that all fixed points of* S *in* $\mathcal{V} \cap \mathcal{U}$ *belongs to* $B(0, R)$.

PROOF. In the course of this proof we denote the given lower and upper solutions α, β by α_0, β_0, respectively. Let us consider problem (2.51), where the function F is defined as in the first part of the proof of Theorem 2.15, with α and β replaced by α_1 and β_1 respectively. In case α_1 or β_1 are not strict for (2.36), and hence for (2.51), we further replace α_1 with $\alpha_1 - 1$ and β_1 with $\beta_1 + 1$. Hence we can suppose that α_1 and β_1 are strict lower and upper solutions of (2.51) such that $\alpha_1 \ll \alpha_0 \ll \beta_1$ and $\alpha_1 \ll \beta_0 \ll \beta_1$. Let us set, for $(i, j) \in \{0, 1\}^2 \setminus \{(0, 0)\}$,

$$\mathcal{U}_{(i,j)} = \bigl\{u \in C_B^{1,0}\bigl(\overline{Q}_T\bigr) \mid \alpha_i \ll u \ll \beta_j\bigr\}.$$

In particular, we have $\mathcal{U}_{(1,1)} = \mathcal{U}$. Notice that $\mathcal{U}_{(i,j)}$ are nonempty open sets in $C_B^{1,0}(\overline{Q}_T)$, since $\alpha_i \ll \beta_j$ for $(i, j) \in \{0, 1\}^2 \setminus \{(0, 0)\}$. Moreover, we have that

$$\mathcal{V} \cap \mathcal{U}_{(1,1)} = \mathcal{U}_{(1,1)} \setminus \overline{(\mathcal{U}_{(0,1)} \cup \mathcal{U}_{(1,0)})}.$$

Let S be the solution operator corresponding to (2.49) and observe that, by Theorem 2.15, all fixed points $u \in \overline{\mathcal{V} \cap \mathcal{U}_{(1,1)}}$ of S satisfy

$$\|u\|_{C^{1,0}(\overline{Q}_T)} < R,$$

for some constant $R > 0$. Then, either there is a solution $u \in \partial\mathcal{V}$ of (2.36) and the existence part of the theorem is proved, or there is no solution $u \in \partial\mathcal{V}$ of (2.36), which means that α_0 and β_0 are strict. In that case, by the additivity-excision property of the degree and Theorem 2.15, we get

$$\begin{aligned}1 &= \deg\bigl(I - S, \mathcal{U}_{(1,1)} \cap B(0,R)\bigr)\\ &= \deg\bigl(I - S, \mathcal{U}_{(0,1)} \cap B(0,R)\bigr) + \deg\bigl(I - S, \mathcal{U}_{(1,0)} \cap B(0,R)\bigr)\\ &\quad + \deg\bigl(I - S, \mathcal{V} \cap \mathcal{U}_{(1,1)} \cap B(0,R)\bigr)\\ &= 2 + \deg\bigl(I - S, \mathcal{V} \cap \mathcal{U}_{(1,1)} \cap B(0,R)\bigr)\end{aligned}$$

and hence

$$\deg\bigl(I - S, \mathcal{V} \cap \mathcal{U}_{(1,1)} \cap B(0,R)\bigr) = -1,$$

where $B(0,R)$ is the open ball of center 0 and radius R in $C^{1,0}_B(\overline{Q}_T)$. This argument yields, in any case, the existence of a solution $u \in \overline{\mathcal{V}} \cap [\alpha_1, \beta_1]$ of (2.36).

Finally, the existence of minimal and maximal solutions follows from Lemma 2.16 with $\mathcal{S} = \mathcal{V} \cap [\alpha_1, \beta_1]$. □

2.5. *The Order Interval Trichotomy and applications*

The aim of this section is to extend to our general context the Order Interval Trichotomy, first proved in [34] for order preserving discrete-time semidynamical systems. We stress once more that our results are obtained without requiring any regularity on the function f besides the Carathéodory conditions. Therefore no continuous or discrete semiflow can be naturally associated with (2.10). Moreover, even if a semiflow were defined by (2.13), there is no apparent reason for which it should be order preserving. Nevertheless with the aid of Proposition 2.3, which plays a crucial role in this context, we can deform our original problem to other problems possessing a certain amount of monotonicity, from which we infer the information needed to prove the existence of some kind of connections.

Once a version of the Order Interval Trichotomy is established, we apply it to the study of the dynamics near one-sided isolated solutions of (2.36), namely we prove the existence of heteroclinic solutions connecting a pair of comparable solutions of (2.36) and we study the qualitative behaviour of solutions of (2.10) lying above a maximal, or below a minimal, solution of (2.36).

Connecting T-periodic solutions by lower or upper solutions

The basic result in this context is the following statement.

PROPOSITION 2.18. *Assume* (D), (A), (C) *and* (N). *Suppose that* u_1, u_2 *are solutions of* (2.36) *such that* $u_1 < u_2$ *and there is no solution* u *of* (2.36) *with* $u_1 < u < u_2$. *Then either*

- *there exists a sequence* $(\alpha_n)_n$ *of proper regular lower solutions of* (2.36) *such that, for each* n, $\alpha_n|_{\overline{Q}_T} \in W^{2,1}_{p,B}(Q_T)$ *and* $u_1 < \alpha_n < u_2$, *which converges weakly in* $W^{2,1}_p(Q_T)$ *and strongly in* $C^{1,0}(\overline{Q}_T)$ *to* u_1 *as* $n \to +\infty$, *or*
- *there exists a sequence* $(\beta_n)_n$ *of proper regular upper solutions of* (2.36) *such that, for each* n, $\beta_n|_{\overline{Q}_T} \in W^{2,1}_{p,B}(Q_T)$ *and* $u_1 < \beta_n < u_2$, *which converges weakly in* $W^{2,1}_p(Q_T)$ *and strongly in* $C^{1,0}(\overline{Q}_T)$ *to* u_2 *as* $n \to +\infty$.

PROOF. Let us set, for every $(x,t) \in \overline{Q}_T$ and $s \in \mathbb{R}$,

$$\gamma(x,t,s) = \max\bigl\{u_1(x,t), \min\bigl\{s, u_2(x,t)\bigr\}\bigr\}.$$

Clearly, $\gamma : \overline{Q}_T \times \mathbb{R} \to \mathbb{R}$ is continuous and, for each $(x,t) \in \overline{Q}_T$, $\gamma(x,t,\cdot) : \mathbb{R} \to \mathbb{R}$ is increasing. Moreover, for $i = 1, 2$, let us set, for a.e. $(x,t) \in Q_T$ and every $\varepsilon > 0$,

$$\begin{aligned}&\omega_i(x,t,\varepsilon)\\ &\quad = \max_{|\xi| \leqslant \varepsilon} \bigl| f\bigl(x,t,u_i(x,t), \nabla_x u_i(x,t) + \xi\bigr) - f\bigl(x,t,u_i(x,t), \nabla_x u_i(x,t)\bigr)\bigr|.\end{aligned}$$

Then define, for a.e. $(x,t) \in Q_T$, every $s \in \mathbb{R}$ and $\xi \in \mathbb{R}^N$,

$$\omega(x,t,s) = \begin{cases} \omega_1\bigl(x,t,u_1(x,t) - s\bigr) & \text{if } s < u_1(x,t),\\ 0 & \text{if } u_1(x,t) \leqslant s \leqslant u_2(x,t),\\ -\omega_2\bigl(x,t,s - u_2(x,t)\bigr) & \text{if } s > u_2(x,t) \end{cases}$$

and

$$\bar{f}(x,t,s,\xi) = f\bigl(x,t,\gamma(x,t,s),\xi\bigr) + \omega(x,t,s).$$

Clearly, $\bar{f} : Q_T \times \mathbb{R} \times \mathbb{R}^N \to \mathbb{R}$ satisfies the Carathéodory condition (C) and the Nagumo condition (N). Let us consider the modified problem

$$\begin{aligned} &\partial_t u + A(x,t,\partial_x)u = \bar{f}(x,t,u,\nabla_x u) && \text{in } Q_T,\\ &u = 0 && \text{on } \Sigma_T,\\ &u(\cdot,0) = u(\cdot,T) && \text{in } \Omega. \end{aligned} \tag{2.54}$$

Further, take $\rho = \max\{\|u_1\|_{L^\infty(Q_T)}, \|u_2\|_{L^\infty(Q_T)}\}$ and let h be the function associated with f and ρ whose existence is guaranteed by Proposition 2.3. Consider, for each $\mu \in [0,1]$, the following problems

$$\begin{aligned} &\partial_t u + A(x,t,\partial_x)u = \mu \bar{f}(x,t,u,\nabla_x u) + (1-\mu)\bigl[\bar{f}(x,t,u_1,\nabla_x u)\\ &\qquad + h(x,t,u_1,\gamma(x,t,u),\nabla_x u) + \omega(x,t,u)\bigr] && \text{in } Q_T,\\ &u = 0 && \text{on } \Sigma_T,\\ &u(\cdot,0) = u(\cdot,T) && \text{in } \Omega \end{aligned} \tag{2.55}$$

and

$$\begin{array}{ll}\partial_t u + A(x,t,\partial_x)u = \mu \bar{f}(x,t,u,\nabla_x u) + (1-\mu)\big[\bar{f}(x,t,u_2,\nabla_x u) & \\ \quad +h(x,t,u_2,\gamma(x,t,u),\nabla_x u) + \omega(x,t,u)\big] & \text{in } Q_T, \\ u = 0 & \text{on } \Sigma_T, \\ u(\cdot,0) = u(\cdot,T) & \text{in } \Omega. \end{array} \tag{2.56}$$

It is clear that, if $\mu = 1$, (2.55) and (2.56) reduce to (2.54). Note that the right hand side of the equations in (2.55) and (2.56) satisfy the Carathéodory condition (C) and the Nagumo condition (N), uniformly with respect to $\mu \in [0,1]$. Proposition 2.10 implies that there is a constant $C > 0$ such that, if u is a solution of (2.55), or (2.56), for any $\mu \in [0,1]$, satisfying $u_1 \leqslant u \leqslant u_2$, then

$$\|u\|_{W_p^{2,1}(Q_T)} \leqslant C. \tag{2.57}$$

CLAIM 1. *For any* $\mu \in [0,1]$, *every solution* u *of* (2.55), *or* (2.56), *satisfies* $u_1 \leqslant u \leqslant u_2$ *and, hence,* (2.57). *In particular,* u_1 *and* u_2 *are the only solutions of* (2.54).

Let u be a solution of (2.55) and prove that $u \geqslant u_1$. The argument is similar to the proof of Theorem 2.6 observing that, if $v = u - u_1$ is such that $v(x,t) < 0$ and $|\nabla_x v(x,t)| \leqslant |v(x,t)|$ on $B \times]t_1, t_0]$, for some ball $B \subseteq \Omega$, then on this set

$$\begin{aligned} \partial_t v + A(x,t,\partial_x)v &= \mu\big[\bar{f}(x,t,u,\nabla_x u) - f(x,t,u_1,\nabla_x u_1)\big] \\ &\quad + (1-\mu)\big[\bar{f}(x,t,u_1,\nabla_x u) - f(x,t,u_1,\nabla_x u_1) \\ &\quad + \omega(x,t,u) + h(x,t,u_1,\gamma(x,t,u),\nabla_x u)\big] \\ &= f(x,t,u_1,\nabla_x u) + \omega_1\big(x,t,\big|v(x,t)\big|\big) - f(x,t,u_1,\nabla_x u_1) \\ &\geqslant f(x,t,u_1,\nabla_x u) - f(x,t,u_1,\nabla_x u_1 + \nabla_x v) \\ &\quad + f(x,t,u_1,\nabla_x u_1) - f(x,t,u_1,\nabla_x u_1) \\ &= 0. \end{aligned}$$

Now, let us prove that $u \leqslant u_2$. Again, we argue as in the proof of Theorem 2.6 observing that, if $v = u_2 - u$ is such that $v(x,t) < 0$ and $|\nabla_x v(x,t)| \leqslant |v(x,t)|$ in $B \times]t_1, t_0]$, for some ball $B \subseteq \Omega$, then on this set

$$\begin{aligned} &\partial_t v + A(x,t,\partial_x)v \\ &\quad = \mu\big[f(x,t,u_2,\nabla_x u_2) - \bar{f}(x,t,u,\nabla_x u)\big] + (1-\mu)\big[f(x,t,u_2,\nabla_x u_2) \\ &\qquad - \bar{f}(x,t,u_1,\nabla_x u) - \omega(x,t,u) - h(x,t,u_1,\gamma(x,t,u),\nabla_x u)\big] \\ &\quad = \mu\big[f(x,t,u_2,\nabla_x u_2) - f(x,t,u_2,\nabla_x u) + \omega_2\big(x,t,\big|v(x,t)\big|\big)\big] \\ &\qquad + (1-\mu)\big[f(x,t,u_2,\nabla_x u_2) - f(x,t,u_1,\nabla_x u) + \omega_2\big(x,t,\big|v(x,t)\big|\big) \\ &\qquad - h(x,t,u_1,u_2,\nabla_x u)\big] \end{aligned}$$

$$
\begin{aligned}
&\geqslant \mu\big[f(x,t,u_2,\nabla_x u_2) - f(x,t,u_2,\nabla_x u) - f(x,t,u_2,\nabla_x u_2) \\
&\quad + f(x,t,u_2,\nabla_x u_2 - \nabla_x v)\big] \\
&\quad + (1-\mu)\big[f(x,t,u_2,\nabla_x u_2) - f(x,t,u_1,\nabla_x u) \\
&\quad - f(x,t,u_2,\nabla_x u_2) + f(x,t,u_2,\nabla_x u_2 - \nabla_x v) + h(x,t,u_2,u_1,\nabla_x u)\big] \\
&\geqslant (1-\mu)\big[-f(x,t,u_1,\nabla_x u) + f(x,t,u_2,\nabla_x u) + h(x,t,u_2,u_1,\nabla_x u)\big] \\
&\geqslant 0.
\end{aligned}
$$

In a completely similar way, it can be seen that the same conclusion holds for (2.56). Hence Claim 1 is proved.

CLAIM 2. *For any* $\mu \in [0,1]$, *every solution of* (2.55) *is a lower solution of* (2.36) *and every solution of* (2.56) *is an upper solution of* (2.36).

We verify only the former statement, since the latter can be proved similarly. Indeed, if u is a solution of (2.55), we have, as $u_1 \leqslant u \leqslant u_2$,

$$
\begin{aligned}
&\partial_t u + A(x,t,\partial_x)u \\
&\quad = \mu \bar f(x,t,u,\nabla_x u) \\
&\qquad + (1-\mu)\big[\bar f(x,t,u_1,\nabla_x u) + h(x,t,u_1,\gamma(x,t,u),\nabla_x u) + \omega(x,t,u)\big] \\
&\quad = \mu f(x,t,u,\nabla_x u) + (1-\mu)\big[f(x,t,u_1,\nabla_x u) + h(x,t,u_1,u,\nabla_x u)\big] \\
&\quad \leqslant \mu f(x,t,u,\nabla_x u) + (1-\mu) f(x,t,u,\nabla_x u) = f(x,t,u,\nabla_x u).
\end{aligned}
$$

Thus, Claim 2 is proved.

Now, let us associate with problems (2.55) and (2.56) the corresponding solution operators $S_{1,\mu}, S_{2,\mu} : C_B^{1,0}(\overline{Q}_T) \to C_B^{1,0}(\overline{Q}_T)$, with $\mu \in [0,1]$, whose fixed points are precisely the solutions of (2.55) and (2.56), respectively. Note that $S_{1,1} = S_{2,1}$ is the solution operator corresponding to (2.54).

CLAIM 3. *For every* $\delta > 0$, $u_1 - \delta$ *and* $u_1 + \delta$ *are, respectively, a lower solution and an upper solution of* (2.55), *with* $\mu = 0$.

As $\operatorname{ess\,inf}_{Q_T} a_0 > 0$, this can be deduced from the fact that

$$
\begin{aligned}
&\bar f\big(x,t,u_1,\nabla_x(u_1-\delta)\big) + h\big(x,t,u_1,\gamma\big(x,t,(u_1-\delta)\big),\nabla_x(u_1-\delta)\big) \\
&\quad = f(x,t,u_1,\nabla_x u_1), \\
&\bar f\big(x,t,u_1,\nabla_x(u_1+\delta)\big) + h\big(x,t,u_1,\gamma\big(x,t,(u_1+\delta)\big),\nabla_x(u_1+\delta)\big) \\
&\quad = f(x,t,u_1,\nabla_x u_1) + h\big(x,t,u_1,\gamma\big(x,t,(u_1+\delta)\big),\nabla_x u_1\big) \\
&\quad \leqslant f(x,t,u_1,\nabla_x u_1)
\end{aligned}
$$

and

$$
\omega(x,t,u_1-\delta) \geqslant 0 \geqslant \omega(x,t,u_1+\delta).
$$

Thus, Claim 3 is proved.

Moreover, $u_1 - \delta$ is a strict lower solution. Indeed, if u is a solution of (2.55) with $\mu = 0$, satisfying $u \geqslant u_1 - \delta$, then $u \geqslant u_1$ and hence $u \gg u_1 - \delta$. On the other hand, for what concerns $u_1 + \delta$, either there is $\delta_0 > 0$ such that, for every $\delta \in \left]0, \delta_0\right[$, $u_1 + \delta$ is a strict upper solution, or for every $\delta_0 > 0$ there are $\delta \in \left]0, \delta_0\right[$ and a solution u_δ of (2.55) with $\mu = 0$, such that $u_1 \leqslant u_\delta \leqslant \min\{u_2, u_1 + \delta\}$ and $u_\delta(x_0, t_0) = u_1(x_0, t_0) + \delta$ for some $(x_0, t_0) \in \overline{Q}_T$. Hence, in the latter case, we have $\|u_1 - u_\delta\|_{L^\infty(Q_T)} = \delta$ and therefore $u_\delta \to u_1$ in $L^\infty(Q_T)$, as $\delta \to 0$. By (2.57) there is a constant $C > 0$ such that $\|u_\delta\|_{W_p^{2,1}(Q_T)} \leqslant C$, for every $\delta \in \left]0, \delta_0\right[$, and therefore $u_\delta \to u_1$ in $C^{1,0}(\overline{Q}_T)$, as $\delta \to 0$. Recalling that each u_δ is a lower solution of (2.36), the conclusion of this Proposition is achieved.

Therefore, let us suppose that there is $\delta_0 > 0$ such that, for every $\delta \in \left]0, \delta_0\right[$, $u_1 + \delta$ is a strict upper solution of (2.55). Accordingly Theorem 2.15 guarantees that, for some $R > 0$ and every $\delta \in \left]0, \delta_0\right[$,

$$\deg\big(I - S_{1,0}, \mathcal{U}_1^\delta \cap B(0, R)\big) = 1, \tag{2.58}$$

where $\mathcal{U}_1^\delta = \{u \in C_B^{1,0}(\overline{Q}_T) \mid u_1 - \delta \ll u \ll u_1 + \delta\}$.

In a similar way one proves the following result.

CLAIM 4. *For every* $\delta > 0$, $u_2 - \delta$ *and* $u_2 + \delta$ *are, respectively, a lower solution and an upper solution of* (2.56), *with* $\mu = 0$.

Moreover, $u_2 + \delta$ is a strict upper solution. On the other hand, for what concerns $u_2 - \delta$, as in Claim 3, we can suppose that there is $\delta_0 > 0$ such that, for every $\delta \in \left]0, \delta_0\right[$, $u_2 - \delta$ is a strict lower solution of (2.56) as otherwise the conclusion is achieved. Accordingly Theorem 2.15 guarantees that, for some $R > 0$ and for every $\delta \in \left]0, \delta_0\right[$,

$$\deg\big(I - S_{2,0}, \mathcal{U}_2^\delta \cap B(0, R)\big) = 1, \tag{2.59}$$

where $\mathcal{U}_2^\delta = \{u \in C_B^{1,0}(\overline{Q}_T) \mid u_2 - \delta \ll u \ll u_2 + \delta\}$.

CLAIM 5. *The functions* $u_1 - 1$ *and* $u_2 + 1$ *are, respectively, a strict lower and a strict upper solution of* (2.54), *i.e. of* (2.55) *and* (2.56) *with* $\mu = 1$.

We have

$$\begin{aligned}
&\partial_t(u_1 - 1) + A(x, t, \partial_x)(u_1 - 1) = \partial_t u_1 + A(x, t, \partial_x)u_1 - a_0 \\
&\quad = f(x, t, u_1, \nabla_x u_1) - a_0 \\
&\quad \leqslant f\big(x, t, \gamma\big(x, t, (u_1 - 1)\big), \nabla_x(u_1 - 1)\big) + \omega_1(x, t, 1) - a_0 \\
&\quad \leqslant \bar{f}\big(x, t, u_1 - 1, \nabla_x(u_1 - 1)\big)
\end{aligned}$$

and

$$\begin{aligned}
&\partial_t(u_2 + 1) + A(x, t, \partial_x)(u_2 + 1) = \partial_t u_2 + A(x, t, \partial_x)u_2 + a_0 \\
&\quad = f(x, t, u_2, \nabla_x u_2) + a_0 \\
&\quad \geqslant f\big(x, t, \gamma\big(x, t, (u_2 + 1)\big), \nabla_x(u_2 + 1)\big) - \omega_2(x, t, 1) + a_0 \\
&\quad \geqslant \bar{f}\big(x, t, u_2 + 1, \nabla_x(u_2 + 1)\big).
\end{aligned}$$

Moreover, $u_1 - 1$ and $u_2 + 1$ are strict, since u_1 and u_2 are the only solutions of (2.54). Thus, Claim 5 is proved.

Accordingly Theorem 2.15 guarantees that, for some $R > 0$,

$$\deg\big(I - S_{1,1}, \mathcal{U} \cap B(0,R)\big) = \deg\big(I - S_{2,1}, \mathcal{U} \cap B(0,R)\big) = 1, \tag{2.60}$$

where $\mathcal{U} = \{u \in C_B^{1,0}(\overline{Q}_T) \mid u_1 - 1 \ll u \ll u_2 + 1\}$. Using again the fact that u_1 and u_2 are the only solutions of (2.55) with $\mu = 1$, we conclude, by the excision and additivity properties of the degree, that

$$\begin{aligned}\deg\big(I - S_{1,1}, \mathcal{U} \cap B(0,R)\big) &= \deg\big(I - S_{1,1}, \big(\mathcal{U}_1^\delta \cup \mathcal{U}_2^\delta\big) \cap B(0,R)\big)\\ &= \deg\big(I - S_{1,1}, \mathcal{U}_1^\delta \cap B(0,R)\big)\\ &\quad + \deg\big(I - S_{1,1}, \mathcal{U}_2^\delta \cap B(0,R)\big)\end{aligned} \tag{2.61}$$

for every $\delta \in\,]0, \min\{1, \delta_0, \|u_1 - u_2\|_\infty\}[$.

Now, let us assume that for every $\delta_0 > 0$ there exists $\delta \in\,]0, \delta_0[$ such that, for every $\mu \in [0,1]$, (2.55) has no solution on $\partial\mathcal{U}_1^\delta$ and (2.56) has no solution on $\partial\mathcal{U}_2^\delta$. The homotopy property of the degree then implies, by (2.58) and (2.59),

$$\deg\big(I - S_{1,1}, \mathcal{U}_1^\delta \cap B(0,R)\big) = \deg\big(I - S_{1,0}, \mathcal{U}_1^\delta \cap B(0,R)\big) = 1$$

and

$$\deg\big(I - S_{2,1}, \mathcal{U}_2^\delta \cap B(0,R)\big) = \deg\big(I - S_{2,0}, \mathcal{U}_2^\delta \cap B(0,R)\big) = 1. \tag{2.62}$$

Finally, combining relations (2.60)–(2.62) and using the fact that $S_{1,1} = S_{2,1}$, we obtain,

$$\begin{aligned}2 &= \deg\big(I - S_{1,0}, \mathcal{U}_1^\delta \cap B(0,R)\big) + \deg\big(I - S_{2,0}, \mathcal{U}_2^\delta \cap B(0,R)\big)\\ &= \deg\big(I - S_{1,1}, \mathcal{U}_1^\delta \cap B(0,R)\big) + \deg\big(I - S_{2,1}, \mathcal{U}_2^\delta \cap B(0,R)\big)\\ &= \deg\big(I - S_{1,1}, \mathcal{U}_1^\delta \cap B(0,R)\big) + \deg\big(I - S_{1,1}, \mathcal{U}_2^\delta \cap B(0,R)\big)\\ &= \deg\big(I - S_{1,1}, \mathcal{U} \cap B(0,R)\big) = 1,\end{aligned}$$

which is a contradiction. Hence we can conclude that there is $\delta_0 > 0$ such that for every $\delta \in\,]0, \delta_0[$ either there is a solution u_δ of (2.55), for some $\mu \in [0,1]$, with $u_\delta \in \partial\mathcal{U}_1^\delta$, and hence $u_1 \leqslant u_\delta \leqslant \min\{u_2, u_1 + \delta\}$ and $\|u_1 - u_\delta\|_{L^\infty(Q_T)} = \delta$, or there is a solution u_δ of (2.56), for some $\mu \in [0,1]$, with $u_\delta \in \partial\mathcal{U}_2^\delta$, and hence $\max\{u_1, u_2 - \delta\} \leqslant u_\delta \leqslant u_2$ and $\|u_2 - u_\delta\|_{L^\infty(Q_T)} = \delta$. Condition (2.57) and recalling that solutions u of (2.55), with $u \neq u_1$, are proper lower solutions of (2.36) and solutions u of (2.56), with $u \neq u_2$, are proper upper solutions of (2.36) yield the conclusion. □

REMARK 2.15. Condition (N) can be obviously replaced in Proposition 2.18 by assuming that there exist $h \in L^p(Q_T)$ and $K > 0$ such that for a.e. $(x,t) \in Q_T$, every $s \in [u_1(x,t), u_2(x,t)]$ and every $\xi \in \mathbb{R}^N$,

$$\left| f(x,t,s,\xi) \right| \leqslant h(x,t) + K|\xi|^2.$$

REMARK 2.16. From the proof of Proposition 2.18 it follows that, if u_1 is isolated in $C^{1,0}(\overline{Q}_T)$ as a fixed point of $I - S_{1,1}$ and $\operatorname{ind}(I - S_{1,1}, u_1) \neq 1$, then there exists a sequence $(\alpha_n)_n$ of proper lower solutions of (2.36) such that, for each n, $\alpha_n|_{\overline{Q}_T} \in W^{2,1}_{p,B}(Q_T)$ and $u_1 < \alpha_n < u_2$, which converges weakly in $W^{2,1}_p(Q_T)$ and strongly in $C^{1,0}(\overline{Q}_T)$ to u_1 as $n \to +\infty$. A similar result holds for u_2.

In order to prove the existence of connecting sequences of lower and upper solutions, the following two results are needed.

LEMMA 2.19. *Assume* (D), (A), (C) *and* (N) *and let z be a solution of* (2.36).

(i) *If α is a proper lower solution of* (2.36) *such that $\alpha < z$, then there exists a proper regular lower solution $\bar{\alpha}$ of* (2.36), *satisfying $\bar{\alpha}|_{\overline{Q}_T} \in W^{2,1}_{p,B}(Q_T)$ and $\alpha < \bar{\alpha} < z$.*

(ii) *If β is a proper upper solution of* (2.36) *such that $\beta > z$, then there exists a proper regular upper solution $\bar{\beta}$ of* (2.36), *satisfying $\bar{\beta}|_{\overline{Q}_T} \in W^{2,1}_{p,B}(Q_T)$ and $z < \bar{\beta} < \beta$.*

PROOF. We only prove the former statement. Let h be the function associated with f by Proposition 2.3 and corresponding to $\rho = \max\{\|\alpha\|_{L^\infty(Q_T)}, \|z\|_{L^\infty(Q_T)}\}$. Consider the periodic problem

$$\begin{array}{ll} \partial_t u + A(x,t,\partial_x)u = f(x,t,\alpha,\nabla_x u) - h(x,t,u,\alpha,\nabla_x u) & \text{in } Q_T, \\ u = 0 & \text{on } \Sigma_T, \\ u(\cdot,0) = u(\cdot,T) & \text{in } \Omega. \end{array} \tag{2.63}$$

The right-hand side of the equation satisfies the Carathéodory condition (C) and the Nagumo condition (N). Since α is a proper lower solution and z is a proper upper solution of (2.63), with $\alpha < z$, by Theorem 2.15, this problem has a solution $\bar{\alpha}$, satisfying $\alpha < \bar{\alpha} < z$. The properties of h imply that $\bar{\alpha}$ is a proper lower solution of (2.36). □

PROPOSITION 2.20. *Assume* (D), (A), (C) *and* (N) *and let z be a solution of* (2.36).

(i) *Let α be a proper lower solution of* (2.36) *such that $\alpha < z$ and there is no solution u of* (2.36) *with $\alpha < u < z$. Then there exists a sequence $(\alpha_n)_n$ of proper regular lower solutions of* (2.36), *such that, for each $n \geqslant 1$, $\alpha_n|_{\overline{Q}_T} \in W^{2,1}_{p,B}(Q_T)$ and $\alpha < \alpha_n < \alpha_{n+1} < z$, which converges weakly in $W^{2,1}_p(Q_T)$ and strongly in $C^{1,0}(\overline{Q}_T)$ to z.*

(ii) *Let β be a proper upper solution of* (2.36) *such that $z < \beta$ and there is no solution u of* (2.36) *with $z < u < \beta$. Then there exists a sequence $(\beta_n)_n$ of proper regular upper solutions of* (2.36), *such that, for each $n \geqslant 1$, $\beta_n|_{\overline{Q}_T} \in W^{2,1}_{p,B}(Q_T)$ and $z < \beta_{n+1} < \beta_n < \beta$, which converges weakly in $W^{2,1}_p(Q_T)$ and strongly in $C^{1,0}(\overline{Q}_T)$ to z.*

PROOF. We only prove the former statement. Repeating recursively the argument of the proof of Lemma 2.19, we get a sequence of proper regular lower solutions $(\alpha_n)_n$ such that $\alpha_0 = \alpha$ and, for each $n \geqslant 1$, $\alpha_n|_{\overline{Q}_T} \in W^{2,1}_{p,B}(Q_T)$, $\alpha < \alpha_{n-1} < \alpha_n < z$ and α_n is a solution of

$$\begin{array}{ll} \partial_t u + A(x,t,\partial_x)u = f(x,t,\alpha_{n-1},\nabla_x u) - h(x,t,u,\alpha_{n-1},\nabla_x u) & \text{in } Q_T, \\ u = 0 & \text{on } \Sigma_T, \\ u(\cdot,0) = u(\cdot,T) & \text{in } \Omega. \end{array} \tag{2.64}$$

Since the right-hand side of the equation in (2.64) satisfies conditions (C) and (N), as in the proof of Proposition 2.12, we see that the sequence $(\alpha_n)_n$ converges weakly in $W^{2,1}_p(Q_T)$ and strongly in $C^{1,0}(\overline{Q}_T)$ to a solution of (2.36), which must be z. □

As a direct consequence of Proposition 2.18 and Proposition 2.20 we are finally able to state our general version of the Order Interval Trichotomy, which extends a result in [34] (see also [58,60]).

THEOREM 2.21. *Assume* (D), (A), (C) *and* (N). *Suppose that* u_1, u_2 *are solutions of* (2.36) *such that* $u_1 < u_2$. *Then either*

- *there is a solution* u *of* (2.36) *with* $u_1 < u < u_2$,

or

- *there exists a double sequence* $(\alpha_m)_{m\in\mathbb{Z}}$ *of proper regular lower solutions of* (2.36), *such that, for each* m, $\alpha_m|_{\overline{Q}_T} \in W^{2,1}_{p,B}(Q_T)$ *and* $u_1 < \alpha_m < u_2$, *which converges weakly in* $W^{2,1}_p(Q_T)$ *and strongly in* $C^{1,0}(\overline{Q}_T)$ *to* u_2 *as* $m \to -\infty$ *and to* u_1 *as* $m \to +\infty$,

or

- *there exists a double sequence* $(\beta_m)_{m\in\mathbb{Z}}$ *of proper regular upper solutions of* (2.36), *such that, for each* m, $\beta_m|_{\overline{Q}_T} \in W^{2,1}_{p,B}(Q_T)$ *and* $u_1 < \beta_m < u_2$, *which converges weakly in* $W^{2,1}_p(Q_T)$ *and strongly in* $C^{1,0}(\overline{Q}_T)$ *to* u_1 *as* $m \to -\infty$ *and to* u_2 *as* $m \to +\infty$.

REMARK 2.17. In the frame of Theorem 2.21, if $u_1 \ll u_2$ and there is no solution u of (2.36) with $u_1 < u < u_2$, then the remaining two alternatives are mutually exclusive.

Heteroclinic solutions

We now interpret Theorem 2.21 in terms of the dynamics of solutions of (2.10) by showing that T-monotone solutions connecting two ordered T-periodic solutions do exist. Our statement extends previous results in [34,58,60]. We point out that the proof of the existence of heteroclinic solutions is more involved here than in the case where uniqueness for the initial value problem and validity of comparison principles are assumed.

Theorem 2.22. *Assume* (D), (A), (C) *and* (N). *Suppose that* u_1, u_2 *are solutions of* (2.36) *such that there is no solution* u *of* (2.36) *with* $u_1 < u < u_2$. *Then there exists a* T*-monotone solution* $z : \overline{\Omega} \times \mathbb{R} \to \mathbb{R}$ *of* (2.10) *such that either*

$$\lim_{t \to -\infty} \left\| z(\cdot, t) - u_1(\cdot, t) \right\|_{C^1(\overline{\Omega})} = 0 \quad \textit{and} \quad \lim_{t \to +\infty} \left\| z(\cdot, t) - u_2(\cdot, t) \right\|_{C^1(\overline{\Omega})} = 0, \tag{2.65}$$

or

$$\lim_{t \to -\infty} \left\| z(\cdot, t) - u_2(\cdot, t) \right\|_{C^1(\overline{\Omega})} = 0 \quad \textit{and} \quad \lim_{t \to +\infty} \left\| z(\cdot, t) - u_1(\cdot, t) \right\|_{C^1(\bar{\Omega})} = 0. \tag{2.66}$$

Proof. According to Proposition 2.18, we assume, for example, the existence of a sequence $(\alpha_n)_n$ of proper regular lower solutions of (2.36) such that, for each n, $\alpha_n|_{\overline{Q}_T} \in W^{2,1}_{p,B}(Q_T)$ and $u_1 < \alpha_n < u_2$, which converges weakly in $W^{2,1}_p(Q_T)$ and strongly in $C^{1,0}(\overline{Q}_T)$ to u_1 as $n \to +\infty$.

For each n, we also consider the solution $\widetilde{\alpha}_n : \overline{\Omega} \times [0, +\infty[\to \mathbb{R}$ of (2.10), with $\widetilde{\alpha}_n(\cdot, 0) = \alpha_n(\cdot, 0)$, $u_1 < \widetilde{\alpha}_n < u_2$ in $\overline{\Omega} \times [0, +\infty[$ and $\|\widetilde{\alpha}_n(\cdot, t) - u_2(\cdot, t)\|_{C^1(\overline{\Omega})} \to 0$ as $t \to +\infty$, whose existence is guaranteed by Proposition 2.13.

We are going to select a subsequence of $(\widetilde{\alpha}_n)_n$, we shall still denote for simplicity by $(\widetilde{\alpha}_n)_n$, as follows. Let us define $\delta = \frac{1}{2}\|u_1 - u_2\|_{L^\infty(Q_T)}$. We first choose $\widetilde{\alpha}_1$ such that there is $m_1 \geqslant 1$ for which $\|\widetilde{\alpha}_1(\cdot, kT) - u_1(\cdot, 0)\|_{L^\infty(\Omega)} < \delta$, if $k \in \{0, \ldots, m_1 - 1\}$, and $\|\widetilde{\alpha}_1(\cdot, m_1 T) - u_1(\cdot, 0)\|_{L^\infty(\Omega)} \geqslant \delta$. Next, we pick $\widetilde{\alpha}_2$ such that there is $m_2 \geqslant m_1 + 1$ for which $\|\widetilde{\alpha}_2(\cdot, kT) - u_1(\cdot, 0)\|_{L^\infty(\Omega)} < \delta$, if $k \in \{0, \ldots, m_2 - 1\}$, and $\|\widetilde{\alpha}_2(\cdot, m_2 T) - u_1(\cdot, 0)\|_{L^\infty(\Omega)} \geqslant \delta$. If we cannot find such a function $\widetilde{\alpha}_2$, then there exist $\ell \in \{1, \ldots, m_1\}$ and a subsequence $(\widetilde{\alpha}_{n_k})_k$ such that $\|\widetilde{\alpha}_{n_k}(\cdot, \ell T) - u_1(\cdot, 0)\|_{L^\infty(\Omega)} \geqslant \delta$. Since $(\widetilde{\alpha}_{n_k})_k$ is bounded in $L^\infty(\Omega \times]0, \ell T[)$, $(\widetilde{\alpha}_{n_k}(\cdot, 0))_k$ is bounded in $W^{2-2/p}_p(\Omega)$ and $\|\widetilde{\alpha}_{n_k}(\cdot, 0) - u_1(\cdot, 0)\|_{L^\infty(\Omega)} \to 0$, by Proposition 2.5 there is a subsequence of $(\widetilde{\alpha}_{n_k})_k$ converging weakly in $W^{2,1}_p(\Omega \times]0, \ell T[)$ to a solution v of

$$\begin{array}{ll} \partial_t u + A(x, t, \partial_x) u = f(x, t, u, \nabla_x u) & \text{in } \Omega \times]0, \ell T[, \\ u = 0 & \text{on } \partial\Omega \times [0, \ell T], \end{array}$$

satisfying $v(\cdot, 0) = u_1(\cdot, 0)$ and $\|v(\cdot, \ell T) - u_1(\cdot, 0)\|_{L^\infty(\Omega)} \geqslant \delta$. Let $i \in \{0, \ldots, \ell - 1\}$ be such that $v(\cdot, (i+1)T) > v(\cdot, iT) = u_1(\cdot, 0)$. Then the function

$$\alpha(x, t) = v(x, t + iT) \quad \text{in } \overline{\Omega} \times [0, T[,$$

is a proper lower solution of (2.36), with $u_1 < \alpha < u_2$ and $\alpha(\cdot, 0) = u_1(\cdot, 0)$. Proposition 2.13 yields the existence of a T-increasing solution $\widetilde{\alpha}$ of (2.13), with $t_0 = 0$ and $u_0 = u_1(\cdot, 0)$, such that

$$\lim_{t \to +\infty} \left\| \widetilde{\alpha}(\cdot, t) - u_2(\cdot, t) \right\|_{C^1(\bar{\Omega})} \to 0.$$

Accordingly there exists a T-increasing solution $z:\overline{\Omega}\times\mathbb{R}\to\mathbb{R}$ of (2.10) satisfying (2.65). Then, proceeding by induction, once $\widetilde{\alpha}_{n-1}$ has been defined, either we construct just as above, a T-increasing solution $z:\overline{\Omega}\times\mathbb{R}\to\mathbb{R}$ of (2.10) satisfying (2.65), or we find $\widetilde{\alpha}_n$ for which there is $m_n\geqslant m_{n-1}+1$ such that $\|\widetilde{\alpha}_n(\cdot,kT)-u_1(\cdot,0)\|_{L^\infty(\Omega)}<\delta$, if $k\in\{0,\dots,m_n-1\}$, and $\|\widetilde{\alpha}_n(\cdot,m_nT)-u_1(\cdot,0)\|_{L^\infty(\Omega)}\geqslant\delta$. Suppose that the latter eventuality always occurs and set, for each n,

$$v_n(x,t)=\widetilde{\alpha}_n(x,t+m_nT)\quad\text{in }\overline{\Omega}\times[-m_nT,0]$$

and, for $k\in\{1,\dots,m_n\}$,

$$v_n^{(k)}(x,t)=v_n(x,t)\quad\text{in }\overline{\Omega}\times\bigl[-kT,-(k-1)T\bigr].$$

Fix $k\geqslant 1$ and observe that the sequence $(v_n^{(k)})_n$, with n such that $m_n\geqslant k+1$, is bounded in $L^\infty(\Omega\times]-(k+1)T,-(k-1)T[)$. Hence, by Proposition 2.10, there is a subsequence $(v^{(k)}_{n^{(k)}_j})_j$ converging weakly in $W^{2,1}_p(\Omega\times]-kT,-(k-1)T[)$ to a solution w_k of

$$\begin{array}{ll}\partial_t u+A(x,t,\partial_x)u=f(x,t,u,\nabla_x u) & \text{in }\Omega\times\bigl]-kT,-(k-1)T\bigr[,\\ u=0 & \text{on }\partial\Omega\times\bigl[-kT,-(k-1)T\bigr].\end{array}$$

Since we can choose the sequence $(n_j^{(k+1)})_j$ to be a subsequence of $(n_j^{(k)})_j$, the sequence $(w_k)_k$ is such that, for each $k\geqslant 1$, $w_{k+1}(\cdot,-kT)=w_k(\cdot,-kT)$ and $\|w_1(\cdot,0)-u_1(\cdot,0)\|_{L^\infty(\Omega)}\geqslant\delta$. Moreover, as each $\widetilde{\alpha}_n$ is T-increasing, we have $w_k(\cdot,-kT)\leqslant w_k(\cdot,-(k-1)T)$. Setting for each $k\geqslant 1$

$$z(x,t)=w_k(x,t)\quad\text{in }\overline{\Omega}\times\bigl[-kT,-(k-1)T\bigr],$$

we get a solution of

$$\begin{array}{ll}\partial_t u+A(x,t,\partial_x)u=f(x,t,u,\nabla_x u) & \text{in }\Omega\times]-\infty,0[,\\ u=0 & \text{on }\partial\Omega\times]-\infty,0],\end{array}$$

which satisfies

$$z(\cdot,-kT)\leqslant z\bigl(\cdot,-(k-1)T\bigr),\tag{2.67}$$

$\|z(\cdot,-kT)-u_1(\cdot,0)\|_{L^\infty(\Omega)}\leqslant\delta$, for any $k\geqslant 1$, and $\|z(\cdot,0)-u_1(\cdot,0)\|_{L^\infty(\Omega)}\geqslant\delta$.

Let us define, for each $k\geqslant 1$,

$$z_k(x,t)=z\bigl(x,t-(k-1)T\bigr)\quad\text{in }\overline{\Omega}\times[-T,0].$$

As z is bounded in $\overline{\Omega} \times \left]-\infty, 0\right]$ and satisfies (2.67), arguing as in the proof of Lemma 2.11, we prove that the sequence $(z_k)_k$ has a subsequence $(z_{k_j})_j$ converging weakly in $W_p^{2,1}(\Omega \times \left]-T, 0\right[)$ and strongly in $C^{1,0}(\overline{\Omega} \times [-T, 0])$ to a solution ζ of

$$\begin{array}{ll} \partial_t u + A(x,t,\partial_x)u = f(x,t,u,\nabla_x u) & \text{in } \Omega \times \left]-T, 0\right[, \\ u = 0 & \text{on } \partial\Omega \times [-T, 0], \\ u(\cdot, 0) = u(\cdot, -T) & \text{in } \Omega, \end{array}$$

that is a solution of (2.36). As $\|\zeta(\cdot,0) - u_1(\cdot,0)\|_{L^\infty(\Omega)} \leqslant \delta$ and $u_1 \leqslant \zeta \leqslant u_2$, we have $\zeta = u_1$. Since this argument applies to show that any subsequence of $(z_k)_k$ has a subsequence which converges weakly in $W_p^{2,1}(\Omega \times \left]-T, 0\right[)$ to u_1, we can conclude that

$$\lim_{t \to -\infty} \left\| z(\cdot,t) - u_1(\cdot,t) \right\|_{C^1(\overline{\Omega})} = 0.$$

At last, as $z(\cdot,-T) \leqslant z(\cdot,0)$, $z(\cdot,0) > u_1(\cdot,0)$ and $\|z(\cdot,-T) - u_1(\cdot,-T)\|_{L^\infty(\Omega)} \leqslant \delta$, we see that $z|_{\overline{\Omega} \times [-T,0[}$ gives rise to a proper lower solution of (2.36) and, by Proposition 2.13, it can be extended to a T-increasing solution of (2.10) defined in $\overline{\Omega} \times \mathbb{R}$ and satisfying (2.65). □

REMARK 2.18. In the frame of Theorem 2.22, if $u_1 \ll u_2$, then the two alternatives are mutually exclusive. Further, if (2.65) holds, then for every $t_0 \in \mathbb{R}$ and every $u_0 \in W_p^{2-2/p}(\Omega)$, with $u_0 = 0$ on $\partial\Omega$ and $u_1(\cdot,t_0) \ll u_0 \leqslant u_2(\cdot,t_0)$ in Ω, there is a solution $u : \overline{\Omega} \times [t_0, +\infty[\to \mathbb{R}$ of (2.13) such that

$$\lim_{t \to +\infty} \left\| u(\cdot,t) - u_2(\cdot,t) \right\|_e = 0.$$

Similar conclusions are valid if (2.66) holds.

Above a maximal, or below a minimal, T-periodic solution

We now apply Theorem 2.22 to discuss the behaviour of solutions of (2.10) lying above a maximal solution of (2.36). Of course, symmetric conclusions can be established for solutions lying below a minimal solution of (2.36).

THEOREM 2.23. *Assume* (D), (A), (C) *and* (N). *Suppose that u_2 is a maximal solution of* (2.36). *Then either there exist $\omega_+ \in \left]-\infty, +\infty\right]$ and a T-increasing solution $z : \overline{\Omega} \times \left]-\infty, \omega_+\right[\to \mathbb{R}$ of* (2.10) *such that $z > u_2$ and*

$$\lim_{t \to -\infty} \left\| z(\cdot,t) - u_2(\cdot,t) \right\|_{C^1(\overline{\Omega})} = 0 \quad \textit{and} \quad \limsup_{t \to \omega_+} \Bigl(\max_{\overline{\Omega}} z(\cdot,t) \Bigr) = +\infty, \tag{2.68}$$

or, for any given $t_0 \in \mathbb{R}$*, there exists a* T*-decreasing solution* $z : \overline{\Omega} \times [t_0, +\infty[\to \mathbb{R}$ *of* (2.10) *such that* $z > u_2$ *and*

$$\lim_{t \to +\infty} \left\| z(\cdot, t) - u_2(\cdot, t) \right\|_{C^1(\overline{\Omega})} = 0. \tag{2.69}$$

PROOF. Take $R > 1 + \max_{\overline{Q}_T} u_2$ and define a function $f_R : Q_T \times \mathbb{R} \times \mathbb{R}^N \to \mathbb{R}$ by setting, for a.e. $(x, t) \in Q_T$ and every $(s, \xi) \in \mathbb{R} \times \mathbb{R}^N$,

$$f_R(x, t, s, \xi) = \begin{cases} f\bigl(x, t, u_2(x, t), \xi\bigr) + \omega\bigl(x, t, u_2(x, t) - s\bigr) & \text{if } s < u_2(x, t), \\ f(x, t, s, \xi) & \text{if } u_2(x, t) \leqslant s \leqslant R, \\ (R + 1 - s) f(x, t, s, \xi) & \text{if } R < s \leqslant R + 1, \\ 0 & \text{if } s > R + 1, \end{cases}$$

where

$$\omega(x, t, \delta) = \max_{|\xi| \leqslant \delta} \Bigl| f\bigl(x, t, u_2(x, t), \nabla_x u_2(x, t) + \xi\bigr) - f\bigl(x, t, u_2(x, t), \nabla_x u_2(x, t)\bigr) \Bigr|.$$

Of course, f_R satisfies the conditions (C) and (N). Consider the modified problem

$$\begin{array}{ll} \partial_t u + A(x, t, \partial_x) u = f_R(x, t, u, \nabla_x u) & \text{in } Q_T, \\ u = 0 & \text{on } \Sigma_T, \\ u(\cdot, 0) = u(\cdot, T) & \text{in } \Omega. \end{array} \tag{2.70}$$

Arguing as in the proof of Theorem 2.15, we see that every solution u of (2.70) is such that $u \geqslant u_2$. Notice that $\beta = R + 2$ is a proper regular upper solution of (2.70). Let us show that it is strict. Otherwise, there exists a solution u of (2.70) satisfying $u < \beta$ but not $u \ll \beta$. Let $v = \beta - u$. Since $v(x, t) > 0$ on $\partial\Omega \times [0, T]$ and $v(x, 0) = v(x, T)$ in Ω, there exists $(x_0, t_0) \in \Omega \times]0, T]$ such that $v(x_0, t_0) = \min_{\overline{Q}_T} v = 0$. Hence we can find an open ball $B \subseteq \Omega$, with $x_0 \in B$, and a point $t_1 \in]0, t_0[$ such that $0 \leqslant v(x, t) \leqslant 1$ in $B \times]t_1, t_0]$ and $v(\bar{x}, \bar{t}) > 0$ for some $(\bar{x}, \bar{t}) \in \bar{B} \times [t_1, t_0]$. Using the definition of f_R and β, we get

$$\partial_t v + A(x, t, \partial_x) v = a_0(R + 2) \geqslant 0,$$

a.e. in $B \times]t_1, t_0[$. Then Proposition 2.2 implies that v is constant in $\bar{B} \times [t_1, t_0]$, which is a contradiction. Assume now that there is no solution u of (2.70) with $u_2 < u \leqslant \beta$. By Lemma 2.19, there exists a proper regular upper solution $\bar{\beta}$ of (2.70) such that $\bar{\beta}|_{\overline{Q}_T} \in W^{2,1}_{p,B}(Q_T)$ and $u_2 < \bar{\beta} < \beta$. Hence, Proposition 2.13 implies that, for any given $t_0 \in \mathbb{R}$, there exists a T-decreasing solution $z : \overline{\Omega} \times [t_0, +\infty[\to \mathbb{R}$ of (2.10), with $z > u_2$, satisfying (2.69).

Next, assume that there exists a solution u of (2.70) with $u > u_2$. Then, as (2.36) has no solution u with $u > u_2$, any possible solution u of (2.70), but u_2, must satisfy

$$\max_{\overline{Q}_T} (u - u_2) \geqslant 1. \tag{2.71}$$

Denote by $\mathcal{S}$ the set of all solutions of (2.70) satisfying (2.71). By Lemma 2.16, there is a minimal solution $v \in \mathcal{S}$ of (2.70). By Theorem 2.22, there exists a T-monotone solution ζ of

$$\begin{array}{ll} \partial_t u + A(x,t,\partial_x)u = f_R(x,t,u,\nabla_x u) & \text{in } \Omega \times \mathbb{R}, \\ u = 0 & \text{on } \partial\Omega \times \mathbb{R}, \end{array}$$

such that either

$$\lim_{t\to-\infty} \left\| \zeta(\cdot,t) - u_2(\cdot,t) \right\|_{C^1(\bar{\Omega})} = 0 \quad \text{and} \quad \lim_{t\to+\infty} \left\| \zeta(\cdot,t) - v(\cdot,t) \right\|_{C^1(\overline{\Omega})} = 0,$$

or

$$\lim_{t\to-\infty} \left\| \zeta(\cdot,t) - v(\cdot,t) \right\|_{C^1(\overline{\Omega})} = 0 \quad \text{and} \quad \lim_{t\to+\infty} \left\| \zeta(\cdot,t) - u_2(\cdot,t) \right\|_{C^1(\bar{\Omega})} = 0.$$

In the former case, there exists $t_0 \in \mathbb{R}$ such that ζ is a solution of

$$\begin{array}{ll} \partial_t u + A(x,t,\partial_x)u = f(x,t,u,\nabla_x u) & \text{in } \Omega \times \left]-\infty, t_0\right], \\ u = 0 & \text{on } \partial\Omega \times \left]-\infty, t_0\right]. \end{array}$$

Proposition 2.13 implies that ζ can be continued to a T-increasing solution z of (2.10), which is defined in $\overline{\Omega} \times \left]-\infty, \omega_+\right[$ for some $\omega_+ \in \left]-\infty, +\infty\right]$ and satisfies (2.68). In the latter case, there exists $\omega_- \in \mathbb{R}$ such that ζ is a solution of

$$\begin{array}{ll} \partial_t u + A(x,t,\partial_x)u = f(x,t,u,\nabla_x u) & \text{in } \Omega \times \left]\omega_-, +\infty\right[, \\ u = 0 & \text{on } \partial\Omega \times \left]\omega_-, +\infty\right[. \end{array}$$

Then, for any given $t_0 \in \mathbb{R}$, we take $k_0 \in \mathbb{N}$ such that $\omega_- - k_0 T < t_0$ and we set $z(x,t) = \zeta(x, t + k_0 T)$ in $\overline{\Omega} \times \left[t_0, +\infty\right[$. Clearly, z is a T-decreasing solution of (2.10) satisfying (2.69). □

2.6. *Stability matters*

In this section we study the stability properties of the T-periodic solutions of (2.10) with the aid of lower and upper solutions. It seems natural to use in this context the order norm $\|\cdot\|_e$ introduced in Definition 2.8. We start by recalling the notion of one-sided Lyapunov–Bellmann stability. Since we have to take care of the fact that uniqueness for the initial value problem and validity of comparison principles are not assumed, such a definition does not generally seem the most appropriate to be considered here; indeed, some weaker concept might fit better in order to detect certain residual forms of stability. As an alternative notion to Lyapunov stability we use here order stability; this is common in the frame of order preserving semidynamical systems [93,33,58,60] and appears suited to our approach based on lower and upper solutions. We remark that Lyapunov stability implies order stability, whereas the converse implication is not generally true; however, these concepts are equivalent if a comparison principle holds for solutions of (2.10). Using these notions, we give a precise description of the stability properties of a T-periodic solution in terms of the existence of a lower or an upper solution close to it. Hence, when a pair of lower and upper solutions α, β, with $\alpha \leqslant \beta$, is given, we discuss the stability of the minimum and the maximum T-periodic solutions v and w lying in between, thus getting a completion of Theorem 2.15. Afterwards, we turn to investigate the behaviour of the solutions between v and w, finding in some cases a totally ordered continuum of order stable T-periodic solutions. Finally, in the complementary case where $\alpha \nleqslant \beta$, we see that Lyapunov instability occurs, thus completing Theorem 2.17.

One-sided Lyapunov stability
The following definitions are in the spirit of [17].

DEFINITION 2.14.

- A solution z of (2.36) is said *Lyapunov stable* (briefly, *$\mathcal{L}$-stable*) *from below* if, for every $\varepsilon > 0$, there is $\delta > 0$ such that, for every $t_0 \in [0, T[$ and for every $u_0 \in W_p^{2-2/p}(\Omega)$, with $u_0 = 0$ on $\partial\Omega$, $u_0 < z(\cdot, t_0)$ and $\|u_0 - z(\cdot, t_0)\|_e < \delta$, every nonextendible solution u of (2.13), with $u \leqslant z$, exists in $\overline{\Omega} \times [t_0, +\infty[$ and satisfies

$$\left\|u(\cdot, t) - z(\cdot, t)\right\|_e < \varepsilon \quad \text{in } [t_0, +\infty[. \tag{2.72}$$

- If, further,

$$\lim_{t \to +\infty} \left\|u(\cdot, t) - z(\cdot, t)\right\|_e = 0, \tag{2.73}$$

  z is said *$\mathcal{L}$-asymptotically stable from below*.
- *$\mathcal{L}$-stability from above* and *$\mathcal{L}$-asymptotic stability from above* are defined similarly.
- A solution z of (2.36) is said *$\mathcal{L}$-stable* if, for every $\varepsilon > 0$, there is $\delta > 0$ such that, for every $t_0 \in [0, T[$ and for every $u_0 \in W_p^{2-2/p}(\Omega)$ with $\|u_0 - z(\cdot, t_0)\|_e < \delta$, every nonextendible solution u of (2.13) exists in $\overline{\Omega} \times [t_0, +\infty[$ and satisfies (2.72).

  If, further, (2.73) holds, z is said *$\mathcal{L}$-asymptotically stable*.
- A solution z of (2.36) is said *$\mathcal{L}$-unstable from below* if it is not $\mathcal{L}$-stable from below. *$\mathcal{L}$-instability from above* and *$\mathcal{L}$-instability* are defined similarly.

REMARK 2.19. The notion of $\mathcal{L}$-stability from below given in Definition 2.14 does not require any condition on solutions $u : \overline{\Omega} \times [t_0, \omega[\to \mathbb{R}$ of (2.13), satisfying $u_0 < z(\cdot, t_0)$, $\|u(\cdot, t_0) - z(\cdot, t_0)\|_e < \delta$, but not $u \leqslant z$. A similar remark holds for the $\mathcal{L}$-stability from above.

One-sided order stability
The following definitions are in the spirit of [93,33].

DEFINITION 2.15.

- A solution z of (2.36) is said *order stable* (briefly, *$\mathcal{O}$-stable*) (respectively *properly $\mathcal{O}$-stable*, respectively *strictly $\mathcal{O}$-stable*) *from below* if there exists a sequence $(\alpha_n)_n$

of regular lower solutions (respectively proper regular lower solutions, respectively strict regular lower solutions) of (2.36) such that, for every n, $\alpha_n < z$ and $\alpha_n = 0$ on Σ_T, and $\|\alpha_n - z\|_e \to 0$ as $n \to +\infty$.

- A solution z of (2.36) is said *$\mathcal{O}$-stable* (respectively *properly $\mathcal{O}$-stable*, respectively *strictly $\mathcal{O}$-stable*) *from above* if there exists a sequence $(\beta_n)_n$ of regular upper solutions (respectively proper regular upper solutions, respectively strict regular upper solutions) of (2.36) such that, for every n, $\beta_n > z$ and $\beta_n = 0$ on Σ_T, and $\|\beta_n - z\|_e \to 0$ as $n \to +\infty$.
- A solution z of (2.36) is said *$\mathcal{O}$-stable* (respectively *properly $\mathcal{O}$-stable*, respectively *strictly $\mathcal{O}$-stable*) if it is $\mathcal{O}$-stable (respectively properly $\mathcal{O}$-stable, respectively strictly $\mathcal{O}$-stable) from below and from above.
- A solution z of (2.36) is said *$\mathcal{O}$-unstable from below* (respectively *properly $\mathcal{O}$-unstable from below*, respectively *strictly $\mathcal{O}$-unstable from below*) if there exists a sequence $(\beta_n)_n$ of regular upper solutions (respectively proper regular upper solutions, respectively strict regular upper solutions) of (2.36) such that, for every n, $\beta_n < z$ and $\beta_n = 0$ on Σ_T, and $\|\beta_n - z\|_e \to 0$ as $n \to +\infty$.
- A solution z of (2.36) is said *$\mathcal{O}$-unstable from above* (respectively *properly $\mathcal{O}$-unstable from above*, respectively *strictly $\mathcal{O}$-unstable from above*) if there exists a sequence $(\alpha_n)_n$ of regular lower solutions (respectively proper regular lower solutions, respectively strict regular lower solutions) of (2.36) such that, for every n, $\alpha_n > z$ and $\alpha_n = 0$ on Σ_T, and $\|\alpha_n - z\|_e \to 0$ as $n \to +\infty$.

REMARK 2.20. The notion of strict $\mathcal{O}$-stability corresponds to the strong stability introduced by H. Matano in [93] and, as pointed out there, it represents a form of structural stability.

REMARK 2.21. In the frame of Theorem 2.15, if α is a proper lower solution, then the minimum solution v of (2.36) is, by virtue of Proposition 2.20, properly $\mathcal{O}$-stable from below and, if β is a proper upper solution, the maximum solution w of (2.36) is properly $\mathcal{O}$-stable from above. If α is a strict lower solution, v is also not $\mathcal{O}$-unstable from below and, if β is a strict upper solution, w is also not $\mathcal{O}$-unstable from above.

REMARK 2.22. In the definition of $\mathcal{O}$-stability the request that the lower and the upper solutions are regular is not essential at the light of Lemma 2.19.

Lyapunov stability and order stability

We show here that $\mathcal{L}$-stability implies $\mathcal{O}$-stability.

DEFINITION 2.16. A solution u of (2.36) is said *isolated from above* (respectively *isolated from below*) *in* $C^{1,0}(\overline{Q}_T)$ if there is no sequence $(u_n)_n$ of solutions of (2.36) such that $u_n > u$ (respectively $u_n < u$) for every n and $u_n \to u$ in $C^{1,0}(\overline{Q}_T)$.

REMARK 2.23. We point out that, under conditions (D), (A), (C) and (N), it is equivalent to say that a solution z of (2.36) is isolated (from above or from below) in $C^{1,0}(\overline{Q}_T)$, or in $L^\infty(Q_T)$, or in $W_p^{2,1}(Q_T)$. This is a direct consequence of Proposition 2.10.

PROPOSITION 2.24. *Assume* (D), (A), (C) *and* (N). *If a solution* z *of* (2.36) *is* $\mathcal{L}$*-stable from above* (*respectively* $\mathcal{L}$*-stable from below, respectively* $\mathcal{L}$*-stable*), *then it is* $\mathcal{O}$*-stable from above* (*respectively* $\mathcal{O}$*-stable from below, respectively* $\mathcal{O}$*-stable*). *Moreover, if* z *is isolated from above* (*respectively from below*) *in* $C^{1,0}(\overline{Q}_T)$, *then it is properly* $\mathcal{O}$*-stable from above* (*respectively from below*).

PROOF. Let z be a solution of (2.36) which is $\mathcal{L}$-stable from above and suppose that z is isolated from above in $C^{1,0}(\overline{Q}_T)$, because otherwise there is a sequence of solutions $(u_n)_n$, with $u_n > z$, converging to z in $C^{1,0}(\overline{Q}_T)$ and hence z is $\mathcal{O}$-stable from above. Let $\rho > 0$ be such that every solution u of (2.36), with $u > z$, satisfies $\|u - z\|_{C^{1,0}(\overline{Q}_T)} \geqslant \rho$. We then argue as in the proof of Theorem 2.23. We take $R > \rho + \max_{\bar{\Omega}} z$ and we define a function $f_R : Q_T \times \mathbb{R} \times \mathbb{R}^N \to \mathbb{R}$ as there, replacing u_2 with z. Consider the modified problem (2.70) and notice that $\beta = R + 2$ is a strict regular upper solution of (2.70).

Assume there is no solution u of (2.70) with $z < u \leqslant \beta$. Then Proposition 2.20 implies that z is properly $\mathcal{O}$-stable from above.

Next, assume that there exists a solution u of (2.70) with $u > z$. Since every solution u of (2.70) is such that $u \geqslant z$ and (2.36) has no solution u, with $\|u - z\|_{C^{1,0}(\overline{Q}_T)} < \rho$, any possible solution u of (2.70), but z, must satisfy

$$\|u - z\|_{C^{1,0}(\overline{Q}_T)} \geqslant \rho. \tag{2.74}$$

Denote by $\mathcal{S}$ the set of all solutions of (2.70) satisfying (2.74). By Lemma 2.16, there is a minimal solution $v \in \mathcal{S}$ of (2.70), with $v > z$. By Proposition 2.18, z is either properly $\mathcal{O}$-stable from above, or properly $\mathcal{O}$-unstable from above. In the latter case, as by Proposition 2.18 $\alpha_n|_{\overline{Q}_T} \in W^{2,1}_{p,B}(Q_T)$ for each n, Proposition 2.13 imply the existence of a sequence $(\widetilde{\alpha}_n)_n$ of solutions of (2.10) such that $\|\widetilde{\alpha}_n(\cdot,0) - z(\cdot,0)\|_e \to 0$ as $n \to +\infty$, but $\limsup_{t\to+\infty} \|\widetilde{\alpha}_n(\cdot,t) - z(\cdot,t)\|_e \geqslant \frac{1}{2}\|v - z\|_e$, thus contradicting the $\mathcal{L}$-stability from above of z. □

Comparison principles

In order to discuss further relations between $\mathcal{O}$-stability and $\mathcal{L}$-stability, we introduce the following versions of the comparison principle for parabolic equations.

DEFINITION 2.17.

- We say that the *first comparison principle* holds for the equation

$$\partial_t u + A(x,t,\partial_x)u = f(x,t,u,\nabla_x u) \tag{2.75}$$

if for every $t_1, t_2 \in \mathbb{R}$, with $t_1 < t_2$, and for every $u_1, u_2 \in W^{2,1}_p(\Omega \times]t_1,t_2[)$, with $p > N + 2$, satisfying

$$\begin{aligned} &\partial_t u_1 + A(x,t,\partial_x)u_1 - f(x,t,u_1,\nabla_x u_1) \\ &\quad \leqslant \partial_t u_2 + A(x,t,\partial_x)u_2 - f(x,t,u_2,\nabla_x u_2) && \text{in } \Omega \times]t_1,t_2[, \\ &u_1 \leqslant u_2 && \text{on } \partial\Omega \times [t_1,t_2], \\ &u_1(\cdot,t_1) \leqslant u_2(\cdot,t_1), && \text{in } \Omega, \end{aligned} \tag{2.76}$$

we have

$$u_1 \leqslant u_2 \quad \text{in } \overline{\Omega} \times [t_1, t_2].$$

- We say that the *second comparison principle* holds for (2.75) if for every $t_1, t_2 \in \mathbb{R}$, with $t_1 < t_2$, and for every $u_1, u_2 \in W_p^{2,1}(\Omega \times]t_1, t_2[)$, with $p > N+2$, satisfying

$$\begin{aligned} &\partial_t u_1 + A(x,t,\partial_x)u_1 - f(x,t,u_1,\nabla_x u_1) \\ &\quad \leqslant \partial_t u_2 + A(x,t,\partial_x)u_2 - f(x,t,u_2,\nabla_x u_2) && \text{in } \Omega \times]t_1, t_2[, \\ &u_1 \leqslant u_2 && \text{in } \overline{\Omega} \times [t_1, t_2], \\ &u_1(\cdot, t_1) < u_2(\cdot, t_1), && \text{in } \Omega, \end{aligned} \tag{2.77}$$

we have

$$u_1 \ll u_2 \quad \text{in } \overline{\Omega} \times]t_1, t_2].$$

The first or the second comparison principle holds provided that f satisfies certain local one-sided Lipschitz conditions.

PROPOSITION 2.25. *Assume* (D) *and* (A). *Moreover, suppose that*

(L$^+$) *for every* $\rho > 0$ *there is a constant* $L \geqslant 0$ *such that, for a.e.* $(x,t) \in Q_T$, *every* r, $s \in [-\rho, \rho]$, *with* $r < s$, *and every* ξ, $\eta \in [-\rho, \rho]^N$,

$$f(x,t,s,\xi) - f(x,t,r,\eta) \leqslant L\big(s - r + |\xi - \eta|\big).$$

Then the first comparison principle holds.

PROOF. Let t_1, t_2, with $t_1 < t_2$, be given and let $u_1, u_2 \in W_p^{2,1}(\Omega \times]t_1, t_2[)$ satisfy (2.76). Let L be the constant associated with $\rho = \max\{\|u_1\|_{C^{1,0}(\overline{\Omega}\times[t_1,t_2])}, \|u_2\|_{C^{1,0}(\overline{\Omega}\times[t_1,t_2])}\}$ by condition (L$^+$). Set $v(x,t) = \mathrm{e}^{-Lt}(u_2(x,t) - u_1(x,t))$ in $\overline{\Omega} \times [t_1, t_2]$ and suppose that $\min_{\overline{\Omega}\times[t_1,t_2]} v < 0$. Since $v(x,t) \geqslant 0$ on $\partial\Omega \times [t_1, t_2]$ and $v(\cdot, t_1) \geqslant 0$ in Ω, there exists $(x_0, t_0) \in \Omega \times]t_1, t_2]$ such that $v(x_0, t_0) = \min_{\overline{\Omega}\times[t_1,t_2]} v$. Hence there exist an open ball $B \subseteq \Omega$, with $x_0 \in B$, and a point $t^* \in]t_1, t_0]$ such that, for a.e. $(x,t) \in B \times]t^*, t_0]$, $v(x,t) < 0$ and

$$\begin{aligned} &\partial_t v + A(x,t,\partial_x)v \\ &\quad = -L\mathrm{e}^{-Lt}(u_2 - u_1) + \mathrm{e}^{-Lt}\partial_t(u_2 - u_1) + \mathrm{e}^{-Lt}A(x,t,\partial_x)(u_2 - u_1) \\ &\quad \geqslant -L\mathrm{e}^{-Lt}(u_2 - u_1) + \mathrm{e}^{-Lt}\big(f(x,t,u_2,\nabla_x u_2) - f(x,t,u_1,\nabla_x u_1)\big) \\ &\quad \geqslant -L\mathrm{e}^{-Lt}(u_2 - u_1) + \mathrm{e}^{-Lt}L(u_2 - u_1) - \mathrm{e}^{-Lt}L|\nabla_x u_2 - \nabla_x u_1| \\ &\quad = -\sum_{n=1}^{N} \tilde{a}_i(x,t)\partial_{x_i} v, \end{aligned}$$

where, for each $i = 1, \ldots, N$, $\tilde{a}_i \in L^\infty(\Omega \times]t_1, t_2[)$ is defined by

$$\tilde{a}_i(x,t) = \begin{cases} L\dfrac{\partial_{x_i} v(x,t)}{|\nabla_x v(x,t)|} & \text{if } \nabla_x v(x,t) \neq 0, \\ 0 & \text{if } \nabla_x v(x,t) = 0. \end{cases}$$

Proposition 2.2 then implies that $v(x,t) = v(x_0,t_0) < 0$ in $B \times]t^*, t_0]$ and therefore, as $\operatorname{ess\,inf}_{Q_T} a_0 > 0$,

$$\partial_t v + A(x,t,\partial_x)v + \sum_{n=1}^{N} \tilde{a}_i(x,t)\partial_{x_i} v = a_0 v < 0$$

a.e. in $B \times]t_1, t_0]$, thus contradicting the previous inequality. Accordingly, we conclude that $\min_{\overline{\Omega}\times[t_1,t_2]} v \geqslant 0$ and hence $u_1 \leqslant u_2$ in $\overline{\Omega} \times [t_1, t_2]$. □

PROPOSITION 2.26. *Assume* (D) *and* (A). *Moreover, suppose that*

(L$^-$) *for every $\rho > 0$ there is a constant $L \geqslant 0$ such that, for a.e. $(x,t) \in Q_T$, every r, $s \in [-\rho, \rho]$, with $r < s$, and every ξ, $\eta \in [-\rho, \rho]^N$,*

$$f(x,t,s,\xi) - f(x,t,r,\eta) \geqslant -L\big(s - r + |\xi - \eta|\big).$$

Then the second comparison principle holds.

PROOF. Let t_1, t_2, with $t_1 < t_2$, be given and let $u_1, u_2 \in W_p^{2,1}(\Omega \times]t_1, t_2[)$ satisfy (2.77). Let L be the constant associated with $\rho = \max\{\|u_1\|_{C^{1,0}(\overline{\Omega}\times[t_1,t_2])}, \|u_2\|_{C^{1,0}(\overline{\Omega}\times[t_1,t_2])}\}$ by condition (L$^-$). Set $v(x,t) = u_2(x,t) - u_1(x,t)$ in $\overline{\Omega} \times [t_1, t_2]$ and suppose that either there is $(x_0, t_0) \in \Omega \times]t_1, t_2]$ such that $v(x_0,t_0) = 0$, or there is $(x_0,t_0) \in \partial\Omega \times]t_1, t_2]$ such that $v(x_0,t_0) = 0$ and $\partial_\nu v(x_0,t_0) = 0$, where ν is the outer normal to Ω at x_0. Since $v \geqslant 0$ in $\overline{\Omega} \times [t_1, t_2]$, this implies $v(x_0,t_0) = \min_{\overline{\Omega}\times[t_1,t_2]} v$. Moreover we have, for a.e. $(x,t) \in \Omega \times]t_1, t_0]$,

$$\begin{aligned} \partial_t v + A(x,t,\partial_x)v &\geqslant f(x,t,u_2,\nabla_x u_2) - f(x,t,u_1,\nabla_x u_1) \\ &\geqslant -Lv - L|\nabla_x v| = -Lv - \sum_{n=1}^{N} \tilde{a}_i(x,t)\partial_{x_i} v, \end{aligned}$$

where, for each $i = 1, \ldots, N$, $\tilde{a}_i \in L^\infty(\Omega \times]t_1, t_2[)$ is defined by

$$\tilde{a}_i(x,t) = \begin{cases} L\dfrac{\partial_{x_i} v(x,t)}{|\nabla_x v(x,t)|} & \text{if } \nabla_x v(x,t) \neq 0, \\ 0 & \text{if } \nabla_x v(x,t) = 0. \end{cases}$$

If $x_0 \in \Omega$, Proposition 2.2 implies that $v(x,t) = v(x_0,t_0) = 0$ in $\bar{\Omega} \times [t_1, t_0]$, thus contradicting the assumption $v(\cdot, t_1) > 0$ in Ω. If $x_0 \in \partial\Omega$ and $v(x,t) > 0$ in $\Omega \times]t_1, t_0]$, Proposition 2.2 implies that $\partial_\nu v(x_0,t_0) < 0$, which is again a contradiction. Hence we conclude that $u_1 \ll u_2$ in $\overline{\Omega} \times]t_1, t_2]$. □

PROPOSITION 2.27. *Assume* (D) *and* (A). *If the second comparison principle holds, then for every* $t_1, t_2 \in \mathbb{R}$, *with* $t_1 < t_2$, *and for every* $u_1, u_2 \in W_p^{2,1}(\Omega \times]t_1, t_2[)$, *with* $p > N+2$, *satisfying*

$$\begin{aligned} &\partial_t u_1 + A(x,t,\partial_x)u_1 - f(x,t,u_1,\nabla_x u_1) \\ &\quad \leqslant \partial_t u_2 + A(x,t,\partial_x)u_2 - f(x,t,u_2,\nabla_x u_2) && \text{in } \Omega \times]t_1, t_2[, \\ &u_1 \leqslant u_2 && \text{on } \partial\Omega \times [t_1, t_2], \\ &u_1(\cdot, t_1) \ll u_2(\cdot, t_1) && \text{in } \Omega, \end{aligned} \tag{2.78}$$

we have

$$u_1 \ll u_2 \quad \text{in } \overline{\Omega} \times [t_1, t_2].$$

PROOF. Let t_1, t_2 be such that $t_1 < t_2$ and let $u_1, u_2 \in W_p^{2,1}(\Omega \times]t_1, t_2[)$ satisfy (2.78). By continuity, we have $t^* = \sup\{t \in]t_1, t_2] \mid u_1(\cdot, t) \ll u_2(\cdot, t) \text{ in } \Omega\} > t_1$. Suppose that $t^* < t_2$. As $u_1(\cdot, t) \leqslant u_2(\cdot, t)$ in $\Omega \times]t_1, t^*]$ and $u_1(\cdot, t_1) < u_2(\cdot, t_1)$ in Ω, the second comparison principle implies, in particular, that $u_1(\cdot, t^*) \ll u_2(\cdot, t^*)$ in Ω, which is a contradiction. Hence we conclude that $u_1 \ll u_2$ in $\overline{\Omega} \times [t_1, t_2]$. □

REMARK 2.24. The first comparison principle implies uniqueness in the future for the initial value problem (2.13). On the contrary, this is not true for the second comparison principle: examples in this direction can be found, for instance, in [16].

Lyapunov and order stability in case of validity of comparison principles

In this section we discuss some relations between the notion of $\mathcal{O}$-stability and that of $\mathcal{L}$-stability when the first or the second comparison principle holds. We start with the following observation.

PROPOSITION 2.28. *Assume* (D), (A), (C) *and* (N). *Further, suppose that the first or the second comparison principle holds. If a solution* z *of* (2.36) *is* $\mathcal{L}$*-stable* (*respectively* $\mathcal{L}$*-asymptotically stable*) *from above and from below, then it is* $\mathcal{L}$*-stable* (*respectively* $\mathcal{L}$*-asymptotically stable*).

PROOF. Let z be a solution of (2.36) which is $\mathcal{L}$-stable from above and from below. Then, for every $\varepsilon > 0$, there is $\delta > 0$ such that, for every $t_0 \in [0, T[$ and for every $v_0, w_0 \in W_p^{2-2/p}(\Omega)$, with $v_0 = w_0 = 0$ on $\partial\Omega$ and $z(\cdot, t_0) - \delta e < v_0 < z(\cdot, t_0) < w_0 < z(\cdot, t_0) + \delta e$, there exist, by Lemma 2.8 and the $\mathcal{L}$-stability from above and from below, solutions $v, w : \overline{\Omega} \times [t_0, +\infty[\to \mathbb{R}$ of (2.13), with $u_0 = v_0$ and $u_0 = w_0$ respectively, such that $z(\cdot, t) - \varepsilon e < v(\cdot, t) < z(\cdot, t) < w(\cdot, t) < z(\cdot, t) + \varepsilon e$ in $[t_0, +\infty[$. Pick now $u_0 \in W_p^{2-2/p}(\Omega)$, with $u_0 = 0$ on $\partial\Omega$ and $z(\cdot, t_0) - \delta e \ll u_0 \ll z(\cdot, t_0) + \delta e$, and let $u : \overline{\Omega} \times [t_0, \omega[\to \mathbb{R}$ be a nonextendible solution of (2.13) which exists by Proposition 2.9. Take $v_0, w_0 \in W_p^{2-2/p}(\Omega)$ such that $v_0 = w_0 = 0$ on $\partial\Omega$ and $z(\cdot, t_0) - \delta e < v_0 \ll u_0 \ll w_0 < z(\cdot, t_0) + \delta e$ and let v and w be the corresponding solutions as in the first part of the proof. If the first comparison principle holds, then, by Corollary 2.7 and Remark 2.24,

$\omega = +\infty$, $v < u < w$ and u satisfies (2.72). If the second comparison principle holds, then, by Proposition 2.27, $v \ll u \ll w$, u exists in $\overline{\Omega} \times [t_0, +\infty[$ and satisfies (2.72). $\square$

PROPOSITION 2.29. *Assume* (D), (A), (C) *and* (N). *Further, suppose that the first comparison principle holds. If a solution z of* (2.36) *is strictly $\mathcal{O}$-stable from below* (*respectively strictly $\mathcal{O}$-stable from above*, *respectively strictly $\mathcal{O}$-stable*), *then it is $\mathcal{L}$-stable from below* (*respectively $\mathcal{L}$-stable from above*, *respectively $\mathcal{L}$-stable*).

PROOF. Since z is strictly $\mathcal{O}$-stable from below, there exists a sequence $(\alpha_n)_n$ of strict regular lower solutions of (2.36) such that, for each n, $\alpha_n \ll z$, $\alpha_n = 0$ on Σ_T and $\|\alpha_n - z\|_e \to 0$ as $n \to +\infty$. Fix $\varepsilon > 0$ and take n such that $\|\alpha_n - z\|_e < \varepsilon$. Since $\alpha_n \ll z$, by Proposition 2.1, there exists a constant $\delta > 0$ such that $\delta e \leqslant z(\cdot, t_0) - \alpha_n(\cdot, t_0)$ for every $t_0 \in [0, T]$. Let $u_0 \in W_p^{2-2/p}(\Omega)$, with $u_0 = 0$ on $\partial\Omega$, be such that $z(\cdot, t_0) - \delta e < u_0 \leqslant z(\cdot, t_0)$. Since $\alpha_n(\cdot, t_0) \leqslant z(\cdot, t_0) - \delta e \leqslant u_0 \leqslant z(\cdot, t_0)$, $\alpha_n|_{\bar{\Omega} \times [t_0, +\infty[}$ is a lower solution and $z|_{\overline{\Omega} \times [t_0, +\infty[}$ is an upper solution of (2.13), Corollary 2.7 implies that there exists a solution $u : \overline{\Omega} \times [t_0, +\infty[\to \mathbb{R}$ of (2.13), which is unique by Remark 2.24, satisfying $\alpha_n \leqslant u \leqslant z$ in $\overline{\Omega} \times [t_0, +\infty[$ and hence $\|u(\cdot, t) - z(\cdot, t)\|_e < \varepsilon$ in $[t_0, +\infty[$. $\square$

LEMMA 2.30. *Assume* (D), (A), (C) *and* (N). *Further, suppose that the second comparison principle holds. If α is a lower solution of* (2.36) *and z is a solution of* (2.36), *with $\alpha < z$, then $\alpha \ll z$.*

PROOF. According to the definition of lower solution, let $0 = \sigma_0 < \sigma_1 < \cdots < \sigma_k = T$ and for each $h \in \{0, \dots, k-1\}$, $\alpha = \max_{1 \leqslant i \leqslant m_h} \alpha_i^{(h)}$ in $\overline{\Omega} \times]\sigma_h, \sigma_{h+1}[$, with $\alpha_i^{(h)} \in W_p^{2,1}(\Omega \times]\sigma_h, \sigma_{h+1}[)$ for every $i \in \{1, \dots, m_h\}$. Since $\alpha < z$, our definition of a lower solution implies that there is a point $t_1 \in]\sigma_h, \sigma_{h+1}[$, for some $h \in \{0, \dots, k-1\}$, such that $\alpha(\cdot, t_1) < z(\cdot, t_1)$ and hence $\alpha_i^{(h)}(\cdot, t_1) < z(\cdot, t_1)$ for each $i \in \{1, \dots, m_h\}$. The second comparison principle implies that $\alpha_i^{(h)} \ll z$ in $\overline{\Omega} \times]t_1, \sigma_{h+1}]$ for each $i \in \{1, \dots, m_h\}$ and therefore $\alpha(\cdot, \sigma_{h+1}) \leqslant \lim_{t \to \sigma_{h+1}^-} \alpha(\cdot, t) = \lim_{t \to \sigma_{h+1}^-} \max_{1 \leqslant i \leqslant m_h} \alpha_i^{(h)}(\cdot, t) \ll z(\cdot, \sigma_{h+1})$ in Ω. Applying recursively the second comparison principle and using the T-periodicity we conclude that $\alpha \ll z$ in $\overline{\Omega} \times [0, T]$. $\square$

REMARK 2.25. Suppose that the second comparison principle holds. Lemma 2.30 implies that a lower solution of (2.36) is strict if and only if it is proper and hence, in particular, that proper $\mathcal{O}$-stability from below is equivalent to strict $\mathcal{O}$-stability from below. Similar conclusions obviously hold for upper solutions, for proper $\mathcal{O}$-stability from above and for proper $\mathcal{O}$-stability.

PROPOSITION 2.31. *Assume* (D), (A), (C) *and* (N). *Further, suppose that the second comparison principle holds. A solution z of* (2.36) *is $\mathcal{O}$-stable from below* (*respectively $\mathcal{O}$-stable from above*, *respectively $\mathcal{O}$-stable*) *if and only if it is $\mathcal{L}$-stable from below* (*respectively $\mathcal{L}$-stable from above*, *respectively $\mathcal{L}$-stable*).

PROOF. Let z be a solution of (2.36), which is $\mathcal{O}$-stable from below, and let $(\alpha_n)_n$ be a sequence of regular lower solutions of (2.36) such that, for each n, $\alpha_n < z$, $\alpha_n = 0$ on Σ_T and $\|\alpha_n - z\|_e \to 0$ as $n \to +\infty$. Fix $\varepsilon > 0$ and take n such that $\|\alpha_n - z\|_e < \varepsilon$. Since, by Lemma 2.30, $\alpha_n \ll z$, Proposition 2.1 implies the existence of a constant $\delta > 0$ such that $\delta e \leqslant z(\cdot, t_0) - \alpha_n(\cdot, t_0)$ for every $t_0 \in [0, T]$. Let $u_0 \in W_p^{2-2/p}(\Omega)$, with $u_0 = 0$ on $\partial\Omega$, be such that $u_0 \leqslant z(\cdot, t_0)$ and $\|u_0 - z(\cdot, t_0)\|_e < \delta$. Since $\alpha_n(\cdot, t_0) \leqslant z(\cdot, t_0) - \delta e \ll u_0 \leqslant z(\cdot, t_0)$, $\alpha_n|_{\bar{\Omega}\times[t_0,+\infty[}$ is a lower solution and $z|_{\overline{\Omega}\times[t_0,+\infty[}$ is an upper solution of (2.13), Corollary 2.7 implies that there exists a solution $u : \overline{\Omega} \times [t_0, +\infty[\to \mathbb{R}$ of (2.13), satisfying $\alpha_n \leqslant u \leqslant z$ in $\bar{\Omega} \times [t_0, +\infty[$ and hence $\|u(\cdot, t) - z(\cdot, t)\|_e < \varepsilon$ in $[t_0, +\infty[$. Moreover, Proposition 2.27 implies that any nonextendible solution $u : \overline{\Omega} \times [t_0, \omega[\to \mathbb{R}$ of (2.13), with $\alpha_n(\cdot, t_0) \ll u_0 \leqslant z(\cdot, t_0)$ and $u \leqslant z$, satisfies $\alpha_n(\cdot, t) \ll u(\cdot, t)$ and hence $\|u(\cdot, t) - z(\cdot, t)\|_e < \varepsilon$ in $\overline{\Omega} \times [t_0, \omega[$. Proposition 2.9 finally implies that $\omega = +\infty$. To conclude we use Proposition 2.24 and Proposition 2.28. ☐

Stability via lower and upper solutions

In this section we use lower and upper solutions α, β, with $\alpha \leqslant \beta$, to describe the stability properties of the T-periodic solutions of (2.36) lying in between. We start with an immediate consequence of Proposition 2.13, which shows a certain form of stability of a one-sided isolated solution z of (2.36) in the presence of a lower solution $\alpha < z$, or of an upper solution $\beta > z$.

PROPOSITION 2.32. *Assume* (D), (A), (C) *and* (N). *Moreover, let z be a solution of* (2.36).

(i) *Let α be a proper lower solution of* (2.36) *such that, for some t_0, $\alpha(\cdot, t_0) \in W_p^{2-2/p}(\Omega)$ and $\alpha(\cdot, t_0) = 0$ on $\partial\Omega$. Assume $\alpha < z$ and there is no solution u of* (2.36) *with $\alpha < u < z$. Then there exists the minimum solution $\widetilde{\alpha} : \overline{\Omega} \times [t_0, +\infty[\to \mathbb{R}$ in $[\alpha, z]$ of* (2.13), *with $u_0 = \alpha(\cdot, t_0)$. Further, $\widetilde{\alpha}$ is T-increasing and satisfies*

$$\lim_{t\to+\infty} \left\|\widetilde{\alpha}(\cdot, t) - z(\cdot, t)\right\|_{C^1(\overline{\Omega})} = 0.$$

(ii) *Let β be a proper upper solution of* (2.36) *such that, for some t_0, $\beta(\cdot, t_0) \in W_p^{2-2/p}(\Omega)$ and $\beta(\cdot, t_0) = 0$ on $\partial\Omega$. Assume $z < \beta$ and there is no solution u of* (2.36) *with $z < u < \beta$. Then there exists the maximum solution $\widetilde{\beta} : \overline{\Omega} \times [t_0, +\infty[\to \mathbb{R}$ in $[z, \beta]$ of* (2.13), *with $u_0 = \beta(\cdot, t_0)$. Further, $\widetilde{\beta}$ is T-decreasing and satisfies*

$$\lim_{t\to+\infty} \left\|\widetilde{\beta}(\cdot, t) - z(\cdot, t)\right\|_{C^1(\overline{\Omega})} = 0.$$

From this proposition we get an attractivity and invariance result, which completes Theorem 2.15. It regards the set of solutions of problem (2.36) lying between α and β. This is a classical topic which has been extensively investigated in the last fifty years (see [124,71,72,33,34,58,37,60]). Unlike all these works, here we require no regularity on the function f besides the Carathéodory conditions. So that our assumptions do not guarantee either uniqueness for the initial value problem or validity of comparison principles, which are the basic tools for applying the theory of order preserving discrete-time semidynamical systems.

THEOREM 2.33. *Assume* (D), (A), (C) *and* (N). *Suppose that* α *is a proper lower solution and* β *is a proper upper solution of* (2.36), *such that, for some* t_0, $\alpha(\cdot, t_0)$, $\beta(\cdot, t_0) \in W_p^{2-2/p}(\Omega)$ *and* $\alpha(\cdot, t_0) = 0$, $\beta(\cdot, t_0) = 0$ *on* $\partial\Omega$. *Finally, assume*

$$\alpha < \beta$$

and denote by v *the minimum solution and by* w *the maximum solution of* (2.36) *in* $[\alpha, \beta]$. *Then the following conclusions hold*:

(i) *there exist a* T*-increasing solution* $\widetilde{\alpha} : \overline{\Omega} \times [t_0, +\infty[\to \mathbb{R}$ *of* (2.13), *with* $u_0 = \alpha(\cdot, t_0)$, *and a* T*-decreasing solution* $\widetilde{\beta} : \overline{\Omega} \times [t_0, +\infty[\to \mathbb{R}$ *of* (2.13), *with* $u_0 = \beta(\cdot, t_0)$, *such that*

$$\alpha < \widetilde{\alpha} \leqslant v \leqslant w \leqslant \widetilde{\beta} < \beta$$

and

$$\lim_{t \to +\infty} \left\| \widetilde{\alpha}(\cdot, t) - v(\cdot, t) \right\|_{C^1(\bar{\Omega})} = 0 = \lim_{t \to +\infty} \left\| \widetilde{\beta}(\cdot, t) - w(\cdot, t) \right\|_{C^1(\bar{\Omega})};$$

(ii) *if* $u_0 \in W_p^{2-2/p}(\Omega)$ *is such that* $u_0 = 0$ *on* $\partial\Omega$ *and* $\alpha(\cdot, t_0) \leqslant u_0 \leqslant v(\cdot, t_0)$, *then there exists a solution* $u : \overline{\Omega} \times [t_0, +\infty[\to \mathbb{R}$ *of* (2.13), *satisfying* $\widetilde{\alpha} \leqslant u \leqslant v$ *and hence*

$$\lim_{t \to +\infty} \left\| u(\cdot, t) - v(\cdot, t) \right\|_e = 0;$$

similarly, if $u_0 \in W_p^{2-2/p}(\Omega)$ *is such that* $u_0 = 0$ *on* $\partial\Omega$ *and* $w(\cdot, t_0) \leqslant u_0 \leqslant \beta(\cdot, t_0)$, *then there exists a solution* $u : \overline{\Omega} \times [t_0, +\infty[\to \mathbb{R}$ *of* (2.13), *satisfying* $w \leqslant u \leqslant \widetilde{\beta}$ *and hence*

$$\lim_{t \to +\infty} \left\| u(\cdot, t) - w(\cdot, t) \right\|_e = 0;$$

(iii) *any solution* u *of* (2.10), *such that* $\alpha \leqslant u \leqslant \beta$ *in* $\overline{\Omega} \times [t_0, +\infty[$ *satisfies* $\widetilde{\alpha} \leqslant u \leqslant \widetilde{\beta}$ *in* $\overline{\Omega} \times [t_0, +\infty[$.

PROOF. We first notice that conclusion (i) directly follows from Proposition 2.32. Next, we take $u_0 \in W_p^{2-2/p}(\Omega)$ such that $u_0 = 0$ on $\partial\Omega$ and $\alpha(\cdot, t_0) \leqslant u_0 \leqslant v(\cdot, t_0)$. Since $\widetilde{\alpha}$ and v are, respectively, a lower and an upper solution in $\overline{\Omega} \times [t_0, +\infty[$ of (2.13), Corollary 2.7 implies the existence of a solution $u : \overline{\Omega} \times [t_0, +\infty[\to \mathbb{R}$ of (2.13), satisfying $\widetilde{\alpha} \leqslant u \leqslant v$ and hence

$$\lim_{t \to +\infty} \left\| u(\cdot, t) - v(\cdot, t) \right\|_e = 0.$$

Similarly, if $u_0 \in W_p^{2-2/p}(\Omega)$ is such that $u_0 = 0$ on $\partial\Omega$ and $w(\cdot, t_0) \leqslant u_0 \leqslant \beta(\cdot, t_0)$, then there is a solution $u : \overline{\Omega} \times [t_0, +\infty[\to \mathbb{R}$ of (2.13), satisfying $w \leqslant u \leqslant \widetilde{\beta}$ and hence

$$\lim_{t\to+\infty} \left\| u(\cdot, t) - w(\cdot, t) \right\|_e = 0.$$

This proves conclusion (ii). Finally, if $u : \overline{\Omega} \times [t_0, +\infty[\to \mathbb{R}$ is any solution of (2.10), satisfying $\alpha \leqslant u \leqslant \beta$, then by the minimality properties of $\widetilde{\alpha}$ described in Proposition 2.13 we conclude that $u \geqslant \widetilde{\alpha}$. In a similar way we prove that $u \leqslant \widetilde{\beta}$. This yields conclusion (iii). □

REMARK 2.26. We assumed in Theorem 2.33 the existence of a common value t_0 such that $\alpha(\cdot, t_0)$, $\beta(\cdot, t_0) \in W_p^{2-2/p}(\Omega)$ and $\alpha(\cdot, t_0) = 0$, $\beta(\cdot, t_0) = 0$ on $\partial\Omega$. Of course, this request is not essential: the above conditions could be satisfied at different values t_0', t_0'', respectively.

The property expressed in Theorem 2.33 is a form of relative attractivity, which is somehow related to the notion of relative stability introduced in [17] and to that of weak positive invariance defined in [15].

Assuming the validity of the second comparison principle, the following stronger stability result holds.

COROLLARY 2.34. *Assume* (D), (A), (C), (N) *and suppose that the second comparison principle holds. Assume that α is a proper lower solution and β is a proper upper solution of* (2.36), *such that, for some t_0, $\alpha(\cdot, t_0)$, $\beta(\cdot, t_0) \in W_p^{2-2/p}(\Omega)$ and $\alpha(\cdot, t_0) = 0$, $\beta(\cdot, t_0) = 0$ on $\partial\Omega$. Further, suppose that $\alpha < \beta$ and denote by v and w the minimum and the maximum solutions of* (2.36) *in* $[\alpha, \beta]$. *Then v is $\mathcal{L}$-asymptotically stable from below and w is $\mathcal{L}$-asymptotically stable from above.*

PROOF. By Remark 2.21, we know that v is properly $\mathcal{O}$-stable from below and hence, by Proposition 2.31, it is $\mathcal{L}$-stable from below. Notice that, by Lemma 2.30, $\alpha \ll v$. Let $\widetilde{\alpha}$ be the solution of (2.13), with $u_0 = \alpha(\cdot, t_0)$, whose existence is guaranteed by Theorem 2.33, satisfying, by Proposition 2.27, $\alpha < \widetilde{\alpha} \ll v$ in $\overline{\Omega} \times [t_0, +\infty[$ and

$$\lim_{t\to+\infty} \left\| \widetilde{\alpha}(\cdot, t) - v(\cdot, t) \right\|_{C^1(\overline{\Omega})} = 0.$$

Then, for every $u_0 \in W_p^{2-2/p}(\Omega)$ such that $u_0 = 0$ on $\partial\Omega$ and $\widetilde{\alpha}(\cdot, t_0) \ll u_0 < v(\cdot, t_0)$, any nonextendible solution u of (2.13) with $u \leqslant v$ satisfies, by Proposition 2.27, $\widetilde{\alpha} \ll u \leqslant v$ in $\overline{\Omega} \times [t_0, +\infty[$ and hence

$$\lim_{t\to+\infty} \left\| u(\cdot, t) - v(\cdot, t) \right\|_e = 0.$$

This implies that v is $\mathcal{L}$-asymptotically stable from below. By a similar argument we get the corresponding conclusion for w. □

REMARK 2.27. Under the assumptions of Corollary 2.34, we have that, for every $u_0 \in W_p^{2-2/p}(\Omega)$ such that $u_0 = 0$ on $\partial\Omega$ and $\widetilde{\alpha}(\cdot, t_0) \ll u_0 \ll \widetilde{\beta}(\cdot, t_0)$, any nonextendible solution $u : \overline{\Omega} \times [t_0, \omega[\to \mathbb{R}$ of (2.13) satisfies, by Proposition 2.27 and Proposition 2.9, $\widetilde{\alpha} \ll u \ll \widetilde{\beta}$ in $\overline{\Omega} \times [t_0, \omega[$ with $\omega = +\infty$.

We conclude this section stating some illustrative results where the existence of the pair of lower and upper solutions α, β is replaced by assumptions relating the behaviour of the function f to the principal eigenvalue λ_1 (see Appendix 2.7). Alternative conditions are discussed in [41,42]. We first apply Corollary 2.34 to show the global $\mathcal{L}$-asymptotic stability of the T-periodic solution of a linear problem.

PROPOSITION 2.35. *Assume* (D) *and* (A). *Let* $q \in L^\infty(Q_T)$ *satisfy* $q(x,t) \leqslant \lambda_1$ *a.e. in* Q_T *and* $q(x,t) < \lambda_1$ *on a set of positive measure. Let* $h \in L^p(Q_T)$, *with* $p > N + 2$. *Then the unique solution* z *of*

$$\begin{array}{ll} \partial_t u + A(x,t,\partial_x)u = q(x,t)u + h(x,t) & \textit{in } Q_T, \\ u = 0 & \textit{on } \Sigma_T, \\ u(\cdot,0) = u(\cdot,T) & \textit{in } \Omega, \end{array} \tag{2.79}$$

is globally $\mathcal{L}$*-asymptotically stable.*

PROOF. Let $\varphi_1 \gg 0$ be the principal eigenfunction (see Proposition 2.49). For any $\sigma > 0$ the functions $\alpha = z - \sigma\varphi_1$ and $\beta = z + \sigma\varphi_1$ are respectively a strict lower and a strict upper solution of problem (2.79), with $\alpha \ll z \ll \beta$. Hence, by Corollary 2.34, z is $\mathcal{L}$-asymptotically stable from below and from above. Now, take $t_0 \in [0, T[$ and $u_0 \in W_p^{2-2/p}(\Omega)$ such that $u_0 = 0$ on $\partial\Omega$. Let $\sigma > 0$ be so large that $\alpha(\cdot, t_0) \leqslant u_0 \leqslant \beta(\cdot, t_0)$ in Ω. By Remark 2.27 the solution u of

$$\begin{array}{ll} \partial_t u + A(x,t,\partial_x)u = q(x,t)u + h(x,t) & \text{in } \Omega \times [t_0, +\infty[, \\ u = 0 & \text{on } \partial\Omega \times [t_0, +\infty[, \\ u(\cdot,t_0) = u_0 & \text{in } \Omega, \end{array}$$

satisfies $\widetilde{\alpha} \ll u \ll \widetilde{\beta}$ in $\overline{\Omega} \times [t_0, +\infty[$, where $\widetilde{\alpha}$, $\widetilde{\beta}$ are the functions whose existence is guaranteed by Theorem 2.33, and hence $\lim_{t\to+\infty} \|u(\cdot,t) - z(\cdot,t)\|_e = 0$. □

For the nonlinear problem (2.36) we state the following stabilization result (see [41,42]). Related, less general, statements can be found in [3,34].

PROPOSITION 2.36. *Assume* (D), (A), (C) *and* (N). *Suppose that there exist functions* $a, b \in L^p(Q_T)$, *with* $p > N + 2$, *and* $\gamma, \Gamma \in L^\infty(Q_T)$, *such that, for a.e.* $(x,t) \in Q_T$ *and all* $(s,\xi) \in \mathbb{R} \times \mathbb{R}^N$ *with* $s \neq 0$,

$$\gamma(x,t)|s| + a(x,t) \leqslant f(x,t,s,\xi)\,\mathrm{sgn}(s) \leqslant \Gamma(x,t)|s| + b(x,t),$$

with $\Gamma(x,t) \leqslant \lambda_1$ *a.e. in* Q_T *and* $\Gamma(x,t) < \lambda_1$ *on a subset of positive measure. Then there exist the minimum solution* v *and the maximum solution* w *of* (2.36). *Moreover, for each* $t_0 \in [0, T[$ *and every* $u_0 \in W_p^{2-2/p}(\Omega)$, *with* $u_0 = 0$ *on* $\partial\Omega$, *the following conclusions hold*:

- *if* $u_0 \leqslant v(\cdot, t_0)$, *then there exists a solution* $u : \bar{\Omega} \times [t_0, +\infty[\to \mathbb{R}$ *of* (2.13) *such that* $u \leqslant v$ *and*
$$\lim_{t\to+\infty} \left\| u(\cdot,t) - v(\cdot,t) \right\|_e = 0;$$
- *if* $u_0 \geqslant w(\cdot, t_0)$, *then there exists a solution* $u : \bar{\Omega} \times [t_0, +\infty[\to \mathbb{R}$ *of* (2.13) *such that* $u \geqslant w$ *and*
$$\lim_{t\to+\infty} \left\| u(\cdot,t) - w(\cdot,t) \right\|_e = 0.$$

PROOF. The proof is carried out through some steps.

CLAIM 1. *There exists* $R > 0$ *such that all solutions* u *of* (2.36) *satisfy* $\|u\|_{C^{1,0}(\overline{Q}_T)} < R$.

Without loss of generality, we can suppose $a(x,t) \leqslant 0 \leqslant b(x,t)$ and $\gamma(x,t) \leqslant \Gamma(x,t)$ a.e. in Q_T. Let $q : Q_T \times \mathbb{R} \times \mathbb{R}^N \to \mathbb{R}$ be a L^p-Carathéodory function, with $p > N + 2$, such that, for a.e. $(x,t) \in Q_T$ and every $(s, \xi) \in \mathbb{R} \times \mathbb{R}^N$,

$$\gamma(x,t) \leqslant q(x,t,s,\xi) \leqslant \Gamma(x,t)$$

and

$$q(x,t,s,\xi) = \max\bigl\{\gamma(x,t), \min\bigl\{s^{-1} f(x,t,s,\xi), \Gamma(x,t)\bigr\}\bigr\}, \quad \text{if } |s| \geqslant 1.$$

Define

$$h(x,t,s,\xi) = f(x,t,s,\xi) - q(x,t,s,\xi)s$$

and observe that there exists a function $c \in L^p(Q_T)$, with $p > N + 2$, such that, for a.e. $(x,t) \in Q_T$ and every $(s, \xi) \in \mathbb{R} \times \mathbb{R}^N$,

$$\bigl|h(x,t,s,\xi)\bigr| \leqslant c(x,t).$$

Assume by contradiction that there exists a sequence $(u_n)_n$ of solutions of (2.36) such that $\|u_n\|_{C^{1,0}(\overline{Q}_T)} \to +\infty$. For each n, set $v_n = u_n / \|u_n\|_{C^{1,0}(\overline{Q}_T)}$. Clearly, v_n satisfies

$$\begin{aligned} &\partial_t v_n + A(x,t,\partial_x) v_n = q(x,t,u_n,\nabla u_n) v_n + \frac{h(x,t,u_n,\nabla u_n)}{\|u_n\|_{C^{1,0}(\overline{Q}_T)}} && \text{in } Q_T, \\ &v_n = 0 && \text{on } \Sigma_T, \\ &v_n(\cdot,0) = v_n(\cdot,T) && \text{in } \Omega. \end{aligned}$$

We have that $q(\cdot,\cdot,u_n,\nabla u_n) \to q$ weakly in $L^p(Q_T)$, where $q \in L^\infty(Q_T)$ satisfies $\gamma(x,t) \leqslant q(x,t) \leqslant \Gamma(x,t)$ a.e. in Q_T, and $h_n(\cdot,\cdot,u_n,\nabla u_n)/\|u_n\|_{C^{1,0}(\overline{Q}_T)} \to 0$ strongly in $L^p(Q_T)$. Moreover, $(v_n)_n$ is bounded in $W^{2,1}_p(Q_T)$ and therefore, possibly passing to a subsequence, it converges weakly in $W^{2,1}_p(Q_T)$ and strongly in $C^{1,0}(\overline{Q}_T)$ to some function v with $\|v\|_{C^{1,0}(\overline{Q}_T)} = 1$. Hence v is a nontrivial solution of

$$\begin{array}{ll} \partial_t v + A(x,t,\partial_x)v = q(x,t)v & \text{in } Q_T, \\ v = 0 & \text{on } \Sigma_T, \\ v(\cdot,0) = v(\cdot,T) & \text{in } \Omega, \end{array}$$

thus contradicting Proposition 2.51. This proves the claim.

CLAIM 2. *There exist a strict regular lower solution α and a strict regular upper solution β of* (2.36) *such that every solution u of* (2.36) *satisfies $\alpha \ll u \ll \beta$.*

Denote by $w_\pm$ the solutions of

$$\begin{array}{ll} \partial_t u + A(x,t,\partial_x)u = \Gamma(x,t)u \pm b(x,t) & \text{in } Q_T, \\ u = 0 & \text{on } \Sigma_T, \\ u(\cdot,0) = u(\cdot,T) & \text{in } \Omega, \end{array}$$

which exist by Proposition 2.51. Proposition 2.49 and Proposition 2.1 then imply the existence of a constant $k > 0$ such that $w_- - k\varphi_1 \ll u \ll w_+ + k\varphi_1$, for all $u \in C^{1,0}(\overline{Q}_T)$ with $\|u\|_{C^{1,0}(\overline{Q}_T)} < R$. It is now easy to verify that $\alpha = w_- - k\varphi_1$ and $\beta = w_+ + k\varphi_1$ are, respectively, strict regular lower and upper solutions of (2.36). The conclusion then follows using Claim 1.

From the above claims, we deduce by Theorem 2.15 the existence of the minimum solution v and the maximum solution w in $[\alpha,\beta]$; as every solution u of (2.36) satisfies $\alpha \leqslant u \leqslant \beta$, v and w are the minimum and the maximum solution. Possibly modifying the choice of k in the definition of α and β, we can assume that, if u_0 is such that $u_0 \leqslant v(\cdot,t_0)$ (respectively $w(\cdot,t_0) \leqslant u_0$), then $\alpha(\cdot,t_0) \leqslant u_0 \leqslant v(\cdot,t_0)$ (respectively $w(\cdot,t_0) \leqslant u_0 \leqslant \beta(\cdot,t_0)$). The result then follows from Theorem 2.33. □

Continua of stable T-periodic solutions

We now prove a result which generalizes [33, Theorem 1] (see also [34,58]) and provides the existence of $\mathcal{O}$-stable solutions of (2.36) in the presence of lower and upper solutions α, β, with $\alpha \leqslant \beta$. It also provides information about the topological structure of the set of $\mathcal{O}$-stable solutions lying between α and β.

In the proof we shall use a property of compact subsets of $C^{1,0}(\overline{Q}_T)$, which are dense-in-itself with respect to the order, analogous to that one we have described in Lemma 1.3 for compact subsets of $C^0([t_0,t_1])$.

DEFINITION 2.18. A subset $\mathcal{S}$ of $C^{1,0}(\overline{Q}_T)$ is said *dense-in-itself with respect to the order* if for any $u_1, u_2 \in \mathcal{S}$, with $u_1 < u_2$, there exists $u_3 \in \mathcal{S}$ with $u_1 < u_3 < u_2$.

The next result can be proved exactly in the same way as Lemma 1.3.

LEMMA 2.37. *Let $\mathcal{S} \subset C^{1,0}(\overline{Q}_T)$ be a compact set which is dense-in-itself with respect to the order. Let $\mathcal{T} \subseteq \mathcal{S}$ be a maximal nondegenerate totally ordered subset of $\mathcal{S}$. Then $\mathcal{T}$ is homeomorphic to a nondegenerate compact interval of $\mathbb{R}$.*

THEOREM 2.38. *Assume* (D), (A), (C) *and* (N). *Suppose that α is a proper lower solution and β is a proper upper solution of* (2.36) *satisfying $\alpha < \beta$. Denote, respectively, by v and w the minimum and the maximum solution of* (2.36) *in* $[\alpha, \beta]$. *Then there exists a totally ordered continuum $\mathcal{K}$ in $C^{1,0}(\overline{Q}_T)$ such that every $u \in \mathcal{K}$ is an $\mathcal{O}$-stable solution of* (2.36) *satisfying $v \leqslant u \leqslant w$; moreover, $u_1 = \min \mathcal{K}$ is properly $\mathcal{O}$-stable from below and $u_2 = \max \mathcal{K}$ is properly $\mathcal{O}$-stable from above.*

PROOF. The proof closely follows up the proof of Theorem 1.33. We denote by $\mathcal{S}_1$ the set of all solutions u of (2.36), with $\alpha \leqslant u \leqslant \beta$, which are properly $\mathcal{O}$-stable from below. Since, by Remark 2.21, the minimum solution v is properly $\mathcal{O}$-stable from below, $\mathcal{S}_1$ is not empty. Notice also that, since $\mathcal{S}_1$ is bounded in $L^\infty(Q_T)$, the Nagumo condition (N) implies, by Proposition 2.10, that this set is bounded in $W_p^{2,1}(Q_T)$ and therefore it is relatively compact in $C^{1,0}(\overline{Q}_T)$. Arguing as in the proof of Theorem 1.33, with the aid here of Lemma 2.16 instead of Lemma 1.15, we prove the existence of a maximal solution u_1 of (2.36) in $\mathcal{S}_1$. Proceeding further as in that proof, we denote by $\mathcal{S}_2$ the set of all solutions u of (2.36), with $u_1 \leqslant u \leqslant \beta$, which are properly $\mathcal{O}$-stable from above. By Remark 2.21, $w \in \mathcal{S}_2$. Arguing as above, we get a minimal solution u_2 of (2.36) in $\mathcal{S}_2$.

If $u_1 = u_2$, the conclusion is achieved. Otherwise we denote by $\mathcal{S}_3$ the set of all solutions u of (2.36), with $u_1 \leqslant u \leqslant u_2$. Notice that $\mathcal{S}_3$ is compact in $C^{1,0}(\overline{Q}_T)$. To show that $\mathcal{S}_3$ is dense-in-itself with respect to the order we argue as in Theorem 1.33, with the aid here of Remark 2.21, to show that no proper lower or upper solution of (2.36) may exist between u_1 and u_2, and of Proposition 2.18. Finally, we fix a solution $u_0 \in \mathcal{S}_3$ and we denote by $\mathcal{S}(u_0)$ a maximal totally ordered subset of $\mathcal{S}_3$, with $u_0 \in \mathcal{S}(u_0)$. Then we apply Lemma 2.37 to prove that $\mathcal{S}(u_0)$ is compact and connected. Clearly, every $u \in \mathcal{S}(u_0)$ is $\mathcal{O}$-stable and $u_1 = \min \mathcal{S}(u_0)$ and $u_2 = \max \mathcal{S}(u_0)$ are properly $\mathcal{O}$-stable from below and above, respectively. □

Assuming the validity of the second comparison principle stronger conclusions can be achieved.

COROLLARY 2.39. *Assume* (D), (A), (C), (N) *and suppose that the second comparison principle holds. Let α be a proper lower solution and β be a proper upper solution of* (2.36) *satisfying $\alpha < \beta$. Denote, respectively, by v and w the minimum and the maximum solution of* (2.36) *in* $[\alpha, \beta]$. *Then there exists a totally ordered continuum $\mathcal{K}$ in $C^{1,0}(\overline{Q}_T)$ such that every $u \in \mathcal{K}$ is a $\mathcal{L}$-stable solution of* (2.36) *satisfying $v \leqslant u \leqslant w$. Moreover, if $u_1 = \min \mathcal{K}$ is isolated from below in $C^{1,0}(\overline{Q}_T)$, then u_1 is $\mathcal{L}$-asymptotically stable from below and if $u_2 = \max \mathcal{K}$ is isolated from above in $C^{1,0}(\overline{Q}_T)$, then u_2 is $\mathcal{L}$-asymptotically stable from above. In particular, if $u_1 = u_2 = u^*$ is isolated in $C^{1,0}(\overline{Q}_T)$, then u^* is $\mathcal{L}$-asymptotically stable.*

PROOF. The former conclusion follows from Theorem 2.38 and Proposition 2.31. The latter conclusion, concerning the $\mathcal{L}$-asymptotic stability from below of u_1, is a consequence of Corollary 2.34. Indeed, since u_1 is isolated from below in $C^{1,0}(\overline{Q}_T)$ and, by Theorem 2.38, is properly $\mathcal{O}$-stable from below, there exists a proper lower solution α^*, with $\alpha^* < u_1$, such that there is no solution u of (2.36) with $\alpha^* < u < u_1$, i.e. u_1 is the minimum solution of (2.36) in $[\alpha^*, \beta]$. Hence u_1 is $\mathcal{L}$-asymptotically stable from below. The conclusion about u_2 follows from a similar argument. The $\mathcal{L}$-asymptotic stability of u^* is a consequence of Proposition 2.28. □

Instability via lower and upper solutions

We now show that the presence of lower and upper solutions α, β, with $\alpha \nleqslant \beta$, yields the existence of unstable T-periodic solutions of (2.10). We stress that all the results in this section are obtained without requiring the validity of any comparison principle.

PROPOSITION 2.40. *Assume* (D), (A), (C) *and* (N). *Let z be a solution of* (2.36). *If z is $\mathcal{O}$-unstable from above and isolated from above in $C^{1,0}(\overline{Q}_T)$, then it is $\mathcal{L}$-unstable from above. If z is $\mathcal{O}$-unstable from below and isolated from below in $C^{1,0}(\overline{Q}_T)$, then it is $\mathcal{L}$-unstable from below.*

PROOF. According to Remark 2.23, we pick $\varepsilon > 0$ such that any solution v of (2.36), with $v > z$, satisfies $\|z - v\|_{L^\infty(Q_T)} \geqslant \varepsilon$. Further, let $(\alpha_n)_n$ be a sequence of regular lower solutions of (2.36) such that $\alpha_n > z$, $\alpha_n = 0$ on Σ_T and $\|\alpha_n - z\|_e \to 0$, as $n \to +\infty$. Fix $t_0 \in [0, T[$. Then, for every $\delta > 0$, there exists n such that, setting $u_0 = \alpha_n(\cdot, t_0)$, we have $u_0 \in W_p^{2-2/p}(\Omega)$, $u_0 = 0$ on $\partial\Omega$, $u_0 \geqslant z(\cdot, t_0)$ and $\|u_0 - z(\cdot, t_0)\|_e < \delta$. Moreover, problem (2.13) has, by Proposition 2.13, a nonextendible solution $u : \overline{\Omega} \times [t_0, \omega[\to \mathbb{R}$, satisfying $u > z$ in $\overline{\Omega} \times [t_0, \omega[$ and either $\lim_{t\to\omega} \|u(\cdot, t)\|_{L^\infty(\Omega)} = +\infty$, or $\lim_{t\to+\infty} \|u(\cdot, t) - v(\cdot, t)\|_{L^\infty(\Omega)} = 0$, for some solution v of (2.36), with $v > z$ and $\|z - v\|_{L^\infty(Q_T)} \geqslant \varepsilon$. Anyhow we conclude that z is $\mathcal{L}$-unstable from above. □

The following result is a counterpart, for what concerns instability, of Proposition 2.32.

PROPOSITION 2.41. *Assume* (D), (A), (C) *and* (N). *Moreover, let z be a solution of* (2.36).

(i) *If α is a strict lower solution of* (2.36) *and β is an upper solution of* (2.36) *such that $\alpha \leqslant \beta$, $\alpha \nleqslant z$, $z < \beta$ and there is no solution u of* (2.36) *satisfying $z < u \leqslant \beta$ and $u \ngeqslant \alpha$, then z is $\mathcal{L}$-unstable from above.*

(ii) *If β is a strict upper solution of* (2.36) *and α is a lower solution of* (2.36) *such that $\alpha \leqslant \beta$, $\beta \ngeqslant z$, $\alpha < z$ and there is no solution u of* (2.36) *satisfying $\alpha \leqslant u < z$ and $u \nleqslant \beta$, then z is $\mathcal{L}$-unstable from below.*

PROOF. We prove only the former statement; the proof of the latter being similar. Let v be the minimum solution of (2.36) in $[\max\{\alpha, z\}, \beta]$ given by Theorem 2.15. Since α is a strict lower solution, we have $v \gg \alpha$ and hence $v > \max\{\alpha, z\}$. Let us observe that there is no solution u of (2.36) such that $z < u < v$. Indeed, if u were such a solution, by the minimality of v, it should satisfy $u \ngeqslant \max\{\alpha, z\}$ and hence $u \ngeqslant \alpha$. This contradicts the assumptions on z. Then Proposition 2.18 implies that either there exists a sequence $(\alpha_n)_n$

of proper regular lower solutions of (2.36) such that, for each n, $\alpha_n|_{\overline{Q}_T} \in W^{2,1}_{p,B}(Q_T)$ and $z < \alpha_n < v$, which converges in $C^{1,0}(\overline{Q}_T)$ to z as $n \to +\infty$, or there exists a sequence $(\beta_n)_n$ of proper regular upper solutions of (2.36) such that, for each n, $\beta_n|_{\overline{Q}_T} \in W^{2,1}_{p,B}(Q_T)$ and $z < \beta_n < v$, which converges in $C^{1,0}(\overline{Q}_T)$ to v as $n \to +\infty$. Let us show that the latter alternative cannot occur. Indeed, otherwise, as $v \gg \alpha$, we could find an upper solution $\hat{\beta}$ of (2.36), with $\max\{\alpha, z\} \leqslant \hat{\beta} < v$. Hence there should exist a solution u of (2.36), with $\max\{\alpha, z\} \leqslant u \leqslant \hat{\beta}$ and therefore $z < u < v$, as $z \ngeq \alpha$. This yields a contradiction with a preceding conclusion. Therefore, the former alternative necessarily occurs, i.e. z is properly $\mathcal{O}$-unstable from above. Arguing as in Proposition 2.40, we get the conclusion. □

An immediate consequence of these statements is the following instability result, in the presence of a lower solution α and an upper solution β satisfying the condition $\alpha \nleq \beta$. It yields a completion of Theorem 2.17; as there, we write

$$\mathcal{V} = \left\{u \in C^{1,0}_B\left(\overline{Q}_T\right) \mid u \ngeq \alpha \text{ and } u \nleq \beta\right\}.$$

THEOREM 2.42. *Assume* (D), (A), (C) *and* (N). *Suppose that α is a strict lower solution and β is a strict upper solution of* (2.36) *satisfying*

$$\alpha \nleq \beta.$$

Further, assume that there exist a lower solution α_1 and an upper solution β_1 of (2.36) *such that $\alpha_1 \leqslant \beta_1$ and $\alpha, \beta \in [\alpha_1, \beta_1]$. Then any minimal solution v and any maximal solution w of* (2.36) *in $\overline{\mathcal{V}} \cap [\alpha_1, \beta_1]$ is, respectively, $\mathcal{L}$-unstable from below and $\mathcal{L}$-unstable from above.*

PROOF. We first notice that, as α is a strict lower solution and β is a strict upper solution, $v, w \in \mathcal{V}$. We then apply the former statement of Proposition 2.41, with β and z replaced respectively by β_1 and w, to show that w is $\mathcal{L}$-unstable from above. Whereas, we apply the latter statement of Proposition 2.41, with α and z replaced respectively by α_1 and v, to show that v is $\mathcal{L}$-unstable from below. □

We conclude this section stating some illustrative results where the existence of the lower and upper solutions α, α_1, β, β_1 is replaced by assumptions relating the behaviour of the function f to the principal eigenvalue λ_1. Alternative conditions can be found in [41,42]. We first discuss the $\mathcal{L}$-instability of the T-periodic solution of a linear problem.

PROPOSITION 2.43. *Assume* (D) *and* (A). *Let $q \in L^\infty(Q_T)$ satisfy $\lambda_1 \leqslant q(x,t) \leqslant \mu$ a.e. in Q_T, with $\mu > \lambda_1$ defined in Proposition* 2.52, *and $\lambda_1 < q(x,t)$ on a subset of positive measure. Let $h \in L^p(Q_T)$, with $p > N + 2$. Then the unique solution z of problem* (2.79) *is $\mathcal{L}$-unstable from below and from above.*

PROOF. Let $\varphi_1 \gg 0$ be the principal eigenfunction. For any $\sigma > 0$ the functions $\alpha = z + \sigma\varphi_1$ and $\beta = z - \sigma\varphi_1$ are respectively a strict lower and a strict upper solution of problem (2.79), with $\alpha \gg z \gg \beta$. Hence z is $\mathcal{O}$-unstable from above and from below. Proposition 2.40 yields the conclusion. □

A nonlinear counterpart of Proposition 2.43 for problem (2.36) is the following instability result (see [41,42]).

PROPOSITION 2.44. *Assume* (D), (A), (C) *and* (N). *Suppose that there exist functions* $a, b \in L^p(Q_T)$, *with* $p > N+2$, *and* $\gamma \in L^\infty(Q_T)$ *such that, for a.e.* $(x,t) \in Q_T$ *and all* $(s,\xi) \in \mathbb{R} \times \mathbb{R}^N$ *with* $s \neq 0$,

$$\gamma(x,t)|s| + a(x,t) \leqslant f(x,t,s,\xi)\,\mathrm{sgn}(s) \leqslant \mu|s| + b(x,t),$$

where $\gamma(x,t) \geqslant \lambda_1$ *a.e. in* Q_T, $\gamma(x,t) > \lambda_1$ *on a subset of positive measure and* μ *is defined in Proposition* 2.52. *Then there exist a minimal solution* v *and a maximal solution* w *of* (2.36) *which are, respectively,* $\mathcal{L}$*-unstable from below and* $\mathcal{L}$*-unstable from above.*

PROOF. The proof is carried out through several steps.

CLAIM 1. *There exists a minimal solution* v *and a maximal solution* w *of* (2.36).

Arguing as in Claim 1 of Proposition 2.36 and using Proposition 2.52 instead of Proposition 2.51, we prove the existence of a constant $M > 0$ such that all solutions u of (2.36) satisfy $\|u\|_{C^{1,0}(\overline{Q}_T)} < M$. Hence we conclude by Lemma 2.16.

CLAIM 2. *There exist a strict regular lower solution* α *and a strict regular upper solution* β *of* (2.36) *such that every solution* u *of* (2.36) *satisfies* $\beta \ll u \ll \alpha$.

Using Proposition 2.52, Proposition 2.49 and Proposition 2.1, we define, as in Claim 2 in the proof of Proposition 2.36, $\alpha = w_+ + k\varphi_1$ and $\beta = w_- - k\varphi_1$, where $w_\pm$ are the solutions of

$$\begin{array}{ll} \partial_t u + A(x,t,\partial_x)u = \gamma(x,t)u \pm a(x,t) & \text{in } Q_T, \\ u = 0 & \text{on } \Sigma_T, \\ u(\cdot,0) = u(\cdot,T) & \text{in } \Omega, \end{array}$$
